This Specification is protected by copyright laws and contains material proprietary to Khronos. Except as described by these terms, it or any components may not be reproduced, republished, distributed, transmitted, displayed, broadcast or otherwise exploited in any manner without the express prior written permission of Khronos. Khronos grants a conditional copyright license to use and reproduce the unmodified Specification for any purpose, without fee or royalty, EXCEPT no licenses to any patent, trademark or other intellectual property rights are granted under these terms.

Khronos makes no, and expressly disclaims any, representations or warranties, express or implied, regarding this Specification, including, without limitation: merchantability, fitness for a particular purpose, non-infringement of any intellectual property, correctness, accuracy, completeness, timeliness, and reliability. Under no circumstances will Khronos, or any of its Promoters, Contributors or Members, or their respective partners, officers, directors, employees, agents or representatives be liable for any damages, whether direct, indirect, special or consequential damages for lost revenues, lost profits, or otherwise, arising from or in connection with these materials.

This Specification has been created under the Khronos Intellectual Property Rights Policy, which is Attachment A of the Khronos Group Membership Agreement available at https://www.khronos.org/files/member_agreement.pdf, and which defines the terms 'Scope', 'Compliant Portion', and 'Necessary Patent Claims'. Parties desiring to implement the Specification and make use of Khronos trademarks in relation to that implementation, and receive reciprocal patent license protection under the Khronos Intellectual Property Rights Policy must become Adopters and confirm the implementation as conformant under the process defined by Khronos for this Specification; see https://www.khronos.org/adopters.

This Specification contains substantially unmodified functionality from, and is a successor to, Khronos specifications including OpenGL, OpenGL ES and OpenCL.

Some parts of this Specification are purely informative and so are EXCLUDED from the Scope of this Specification. The Document Conventions section of the Introduction defines how these parts of the Specification are identified.

Where this Specification uses technical terminology, defined in the Glossary or otherwise, that refer to enabling technologies that are not expressly set forth in this Specification, those enabling technologies are EXCLUDED from the Scope of this Specification. For clarity, enabling technologies not disclosed with particularity in this Specification (e.g. semiconductor manufacturing technology, hardware architecture, processor architecture or microarchitecture, memory architecture, compiler technology, object oriented technology, basic operating system technology, compression technology, algorithms, and so on) are NOT to be considered expressly set forth; only those application program interfaces and data structures disclosed with particularity are included in the Scope of this Specification.

For purposes of the Khronos Intellectual Property Rights Policy as it relates to the definition of Necessary Patent Claims, all recommended or optional features, behaviors and functionality set forth in this Specification, if implemented, are considered to be included as Compliant Portions.
Where this Specification includes normative references to external documents, only the specifically identified sections of those external documents are INCLUDED in the Scope of this Specification. If not created by Khronos, those external documents may contain contributions from non-members of Khronos not covered by the Khronos Intellectual Property Rights Policy.

This document contains extensions which are not ratified by Khronos, and as such is not a ratified Specification, though it contains text from (and is a superset of) the ratified Vulkan Specification. The ratified versions of the Vulkan Specification can be found at https://www.khronos.org/registry/vulkan/specs/1.2/html/vkspec.html (core only) and https://www.khronos.org/registry/vulkan/specs/1.2-khr-extensions/html/vkspec.html (core with KHR extensions).

Vulkan and Khronos are registered trademarks of The Khronos Group Inc. ASTC is a trademark of ARM Holdings PLC; OpenCL is a trademark of Apple Inc.; and OpenGL and OpenGL ES are registered trademarks of Hewlett Packard Enterprise, all used under license by Khronos. All other product names, trademarks, and/or company names are used solely for identification and belong to their respective owners.
Chapter 1. Introduction

This document, referred to as the “Vulkan Specification” or just the “Specification” hereafter, describes the Vulkan Application Programming Interface (API). Vulkan is a C99 API designed for explicit control of low-level graphics and compute functionality.

The canonical version of the Specification is available in the official Vulkan Registry (https://www.khronos.org/registry/vulkan/). The source files used to generate the Vulkan specification are stored in the Vulkan Documentation Repository (https://github.com/KhronosGroup/Vulkan-Docs). The source repository additionally has a public issue tracker and allows the submission of pull requests that improve the specification.

1.1. Document Conventions

The Vulkan specification is intended for use by both implementors of the API and application developers seeking to make use of the API, forming a contract between these parties. Specification text may address either party; typically the intended audience can be inferred from context, though some sections are defined to address only one of these parties. (For example, Valid Usage sections only address application developers). Any requirements, prohibitions, recommendations or options defined by normative terminology are imposed only on the audience of that text.

Structure and enumerated types defined in extensions that were promoted to core in Vulkan 1.1 are now defined in terms of the equivalent Vulkan 1.1 interfaces. This affects the Vulkan Specification, the Vulkan header files, and the corresponding XML Registry.

1.1.1. Normative Terminology

Within this specification, the key words must, required, should, recommended, may, and optional are to be interpreted as described in RFC 2119 - Key words for use in RFCs to Indicate Requirement Levels (https://www.ietf.org/rfc/rfc2119.txt). These key words are highlighted in the specification for clarity. In text addressing application developers, their use expresses requirements that apply to application behavior. In text addressing implementors, their use expresses requirements that apply to implementations.

In text addressing application developers, the additional key words can and cannot are to be interpreted as describing the capabilities of an application, as follows:

can

This word means that the application is able to perform the action described.

cannot

This word means that the API and/or the execution environment provide no mechanism through which the application can express or accomplish the action described.

These key words are never used in text addressing implementors.
Note
There is an important distinction between cannot and must not, as used in this Specification. Cannot means something the application literally is unable to express or accomplish through the API, while must not means something that the application is capable of expressing through the API, but that the consequences of doing so are undefined and potentially unrecoverable for the implementation (see Errors).

Unless otherwise noted in the section heading, all sections and appendices in this document are normative.

1.1.2. Technical Terminology

The Vulkan Specification makes use of common engineering and graphics terms such as Pipeline, Shader, and Host to identify and describe Vulkan API constructs and their attributes, states, and behaviors. The Glossary defines the basic meanings of these terms in the context of the Specification. The Specification text provides fuller definitions of the terms and may elaborate, extend, or clarify the Glossary definitions. When a term defined in the Glossary is used in normative language within the Specification, the definitions within the Specification govern and supersede any meanings the terms may have in other technical contexts (i.e. outside the Specification).

1.1.3. Normative References

References to external documents are considered normative references if the Specification uses any of the normative terms defined in Normative Terminology to refer to them or their requirements, either as a whole or in part.

The following documents are referenced by normative sections of the specification:

Chapter 2. Fundamentals

This chapter introduces fundamental concepts including the Vulkan architecture and execution model, API syntax, queues, pipeline configurations, numeric representation, state and state queries, and the different types of objects and shaders. It provides a framework for interpreting more specific descriptions of commands and behavior in the remainder of the Specification.

2.1. Host and Device Environment

The Vulkan Specification assumes and requires: the following properties of the host environment with respect to Vulkan implementations:

- The host must have runtime support for 8, 16, 32 and 64-bit signed and unsigned two's-complement integers, all addressable at the granularity of their size in bytes.
- The host must have runtime support for 32- and 64-bit floating-point types satisfying the range and precision constraints in the Floating Point Computation section.
- The representation and endianness of these types on the host must match the representation and endianness of the same types on every physical device supported.

Note
Since a variety of data types and structures in Vulkan may be accessible by both host and physical device operations, the implementation should be able to access such data efficiently in both paths in order to facilitate writing portable and performant applications.

2.2. Execution Model

This section outlines the execution model of a Vulkan system.

Vulkan exposes one or more devices, each of which exposes one or more queues which may process work asynchronously to one another. The set of queues supported by a device is partitioned into families. Each family supports one or more types of functionality and may contain multiple queues with similar characteristics. Queues within a single family are considered compatible with one another, and work produced for a family of queues can be executed on any queue within that family. This Specification defines four types of functionality that queues may support: graphics, compute, transfer, and sparse memory management.

Note
A single device may report multiple similar queue families rather than, or as well as, reporting multiple members of one or more of those families. This indicates that while members of those families have similar capabilities, they are not directly compatible with one another.

Device memory is explicitly managed by the application. Each device may advertise one or more heaps, representing different areas of memory. Memory heaps are either device local or host local,
but are always visible to the device. Further detail about memory heaps is exposed via memory types available on that heap. Examples of memory areas that may be available on an implementation include:

- **device local** is memory that is physically connected to the device.
- **device local, host visible** is device local memory that is visible to the host.
- **host local, host visible** is memory that is local to the host and visible to the device and host.

On other architectures, there may only be a single heap that can be used for any purpose.

A Vulkan application controls a set of devices through the submission of command buffers which have recorded device commands issued via Vulkan library calls. The content of command buffers is specific to the underlying implementation and is opaque to the application. Once constructed, a command buffer can be submitted once or many times to a queue for execution. Multiple command buffers can be built in parallel by employing multiple threads within the application.

Command buffers submitted to different queues may execute in parallel or even out of order with respect to one another. Command buffers submitted to a single queue respect submission order, as described further in synchronization chapter. Command buffer execution by the device is also asynchronous to host execution. Once a command buffer is submitted to a queue, control may return to the application immediately. Synchronization between the device and host, and between different queues is the responsibility of the application.

### 2.2.1. Queue Operation

Vulkan queues provide an interface to the execution engines of a device. Commands for these execution engines are recorded into command buffers ahead of execution time. These command buffers are then submitted to queues with a queue submission command for execution in a number of batches. Once submitted to a queue, these commands will begin and complete execution without further application intervention, though the order of this execution is dependent on a number of implicit and explicit ordering constraints.

Work is submitted to queues using queue submission commands that typically take the form `vkQueue*` (e.g. `vkQueueSubmit`, `vkQueueBindSparse`), and optionally take a list of semaphores upon which to wait before work begins and a list of semaphores to signal once work has completed. The work itself, as well as signaling and waiting on the semaphores are all queue operations.

Queue operations on different queues have no implicit ordering constraints, and may execute in any order. Explicit ordering constraints between queues can be expressed with semaphores and fences.

Command buffer submissions to a single queue respect submission order and other implicit ordering guarantees, but otherwise may overlap or execute out of order. Other types of batches and queue submissions against a single queue (e.g. sparse memory binding) have no implicit ordering constraints with any other queue submission or batch. Additional explicit ordering constraints between queue submissions and individual batches can be expressed with semaphores and fences.

Before a fence or semaphore is signaled, it is guaranteed that any previously submitted queue operations have completed execution, and that memory writes from those queue operations are
available to future queue operations. Waiting on a signaled semaphore or fence guarantees that previous writes that are available are also visible to subsequent commands.

Command buffer boundaries, both between primary command buffers of the same or different batches or submissions as well as between primary and secondary command buffers, do not introduce any additional ordering constraints. In other words, submitting the set of command buffers (which can include executing secondary command buffers) between any semaphore or fence operations execute the recorded commands as if they had all been recorded into a single primary command buffer, except that the current state is reset on each boundary. Explicit ordering constraints can be expressed with explicit synchronization primitives.

There are a few implicit ordering guarantees between commands within a command buffer, but only covering a subset of execution. Additional explicit ordering constraints can be expressed with the various explicit synchronization primitives.

Note
Implementations have significant freedom to overlap execution of work submitted to a queue, and this is common due to deep pipelining and parallelism in Vulkan devices.

Commands recorded in command buffers either perform actions (draw, dispatch, clear, copy, query/timestamp operations, begin/end subpass operations), set state (bind pipelines, descriptor sets, and buffers, set dynamic state, push constants, set render pass/subpass state), or perform synchronization (set/wait events, pipeline barrier, render pass/subpass dependencies). Some commands perform more than one of these tasks. State setting commands update the current state of the command buffer. Some commands that perform actions (e.g. draw/dispatch) do so based on the current state set cumulatively since the start of the command buffer. The work involved in performing action commands is often allowed to overlap or to be reordered, but doing so must not alter the state to be used by each action command. In general, action commands are those commands that alter framebuffer attachments, read/write buffer or image memory, or write to query pools.

Synchronization commands introduce explicit execution and memory dependencies between two sets of action commands, where the second set of commands depends on the first set of commands. These dependencies enforce that both the execution of certain pipeline stages in the later set occur after the execution of certain stages in the source set, and that the effects of memory accesses performed by certain pipeline stages occur in order and are visible to each other. When not enforced by an explicit dependency or implicit ordering guarantees, action commands may overlap execution or execute out of order, and may not see the side effects of each other’s memory accesses.

The device executes queue operations asynchronously with respect to the host. Control is returned to an application immediately following command buffer submission to a queue. The application must synchronize work between the host and device as needed.

2.3. Object Model

The devices, queues, and other entities in Vulkan are represented by Vulkan objects. At the API
level, all objects are referred to by handles. There are two classes of handles, dispatchable and non-
dispatchable. Dispatchable handle types are a pointer to an opaque type. This pointer may be used
by layers as part of intercepting API commands, and thus each API command takes a dispatchable
type as its first parameter. Each object of a dispatchable type must have a unique handle value
during its lifetime.

Non-dispatchable handle types are a 64-bit integer type whose meaning is implementation-
dependent, and may encode object information directly in the handle rather than acting as a reference to an underlying object. Objects of a non-dispatchable type may not have unique handle values within a type or across types. If handle values are not unique, then destroying one such handle must not cause identical handles of other types to become invalid, and must not cause identical handles of the same type to become invalid if that handle value has been created more times than it has been destroyed.

All objects created or allocated from a VkDevice (i.e. with a VkDevice as the first parameter) are private to that device, and must not be used on other devices.

2.3.1. Object Lifetime

Objects are created or allocated by vkCreate* and vkAllocate* commands, respectively. Once an object is created or allocated, its “structure” is considered to be immutable, though the contents of certain object types is still free to change. Objects are destroyed or freed by vkDestroy* and vkFree* commands, respectively.

Objects that are allocated (rather than created) take resources from an existing pool object or memory heap, and when freed return resources to that pool or heap. While object creation and destruction are generally expected to be low-frequency occurrences during runtime, allocating and freeing objects can occur at high frequency. Pool objects help accommodate improved performance of the allocations and frees.

It is an application’s responsibility to track the lifetime of Vulkan objects, and not to destroy them while they are still in use.

The ownership of application-owned memory is immediately acquired by any Vulkan command it is passed into. Ownership of such memory must be released back to the application at the end of the duration of the command, so that the application can alter or free this memory as soon as all the commands that acquired it have returned.

The following object types are consumed when they are passed into a Vulkan command and not further accessed by the objects they are used to create. They must not be destroyed in the duration of any API command they are passed into:

- VkShaderModule
- VkPipelineCache
- VkValidationCacheEXT

A VkRenderPass object passed as a parameter to create another object is not further accessed by that object after the duration of the command it is passed into. A VkRenderPass used in a command buffer follows the rules described below.
A `VkPipelineLayout` object **must** not be destroyed while any command buffer that uses it is in the recording state.

`VkDescriptorSetLayout` objects **may** be accessed by commands that operate on descriptor sets allocated using that layout, and those descriptor sets **must** not be updated with `vkUpdateDescriptorSets` after the descriptor set layout has been destroyed. Otherwise, a `VkDescriptorSetLayout` object passed as a parameter to create another object is not further accessed by that object after the duration of the command it is passed into.

The application **must** not destroy any other type of Vulkan object until all uses of that object by the device (such as via command buffer execution) have completed.

The following Vulkan objects **must** not be destroyed while any command buffers using the object are in the **pending state**:

- `VkEvent`
- `VkQueryPool`
- `VkBuffer`
- `VkBufferView`
- `VkImage`
- `VkImageView`
- `VkPipeline`
- `VkSampler`
- `VkSamplerYcbcrConversion`
- `VkDescriptorPool`
- `VkFramebuffer`
- `VkRenderPass`
- `VkCommandBuffer`
- `VkCommandPool`
- `VkDeviceMemory`
- `VkDescriptorSet`
- `VkIndirectCommandsLayoutNV`

Destroying these objects will move any command buffers that are in the **recording or executable state**, and are using those objects, to the **invalid state**.

The following Vulkan objects **must** not be destroyed while any queue is executing commands that use the object:

- `VkFence`
- `VkSemaphore`
- `VkCommandBuffer`
In general, objects can be destroyed or freed in any order, even if the object being freed is involved in the use of another object (e.g. use of a resource in a view, use of a view in a descriptor set, use of a pipeline library in another pipeline, use of a referenced pipeline for additional graphics shader groups in another pipeline, use of an object in a command buffer, binding of a memory allocation to a resource), as long as any object that uses the freed object is not further used in any way except to be destroyed or to be reset in such a way that it no longer uses the other object (such as resetting a command buffer). If the object has been reset, then it can be used as if it never used the freed object. An exception to this is when there is a parent/child relationship between objects. In this case, the application must not destroy a parent object before its children, except when the parent is explicitly defined to free its children when it is destroyed (e.g. for pool objects, as defined below).

VkCommandPool objects are parents of VkCommandBuffer objects. VkDescriptorPool objects are parents of VkDescriptorSet objects. VkDevice objects are parents of many object types (all that take a VkDevice as a parameter to their creation).

The following Vulkan objects have specific restrictions for when they can be destroyed:

- VkQueue objects cannot be explicitly destroyed. Instead, they are implicitly destroyed when the VkDevice object they are retrieved from is destroyed.
- Destroying a pool object implicitly frees all objects allocated from that pool. Specifically, destroying VkCommandPool frees all VkCommandBuffer objects that were allocated from it, and destroyingVkDescriptorPool frees all VkDescriptorSet objects that were allocated from it.
- VkDevice objects can be destroyed when all VkQueue objects retrieved from them are idle, and all objects created from them have been destroyed. This includes the following objects:
  - VkFence
  - VkSemaphore
  - VkEvent
  - VkQueryPool
  - VkBuffer
  - VkBufferView
  - VkImage
  - VkImageView
  - VkShaderModule
  - VkPipelineCache
  - VkPipeline
  - VkPipelineLayout
  - VkSampler
  - VkSamplerYcbcrConversion
  - VkDescriptorSetLayout
  - VkDescriptorPool
• VkPhysicalDevice objects cannot be explicitly destroyed. Instead, they are implicitly destroyed when the VkInstance object they are retrieved from is destroyed.

• VkInstance objects can be destroyed once all VkDevice objects created from any of its VkPhysicalDevice objects have been destroyed.

2.3.2. External Object Handles

As defined above, the scope of object handles created or allocated from a VkDevice is limited to that logical device. Objects which are not in scope are said to be external. To bring an external object into scope, an external handle must be exported from the object in the source scope and imported into the destination scope.

Note
The scope of external handles and their associated resources may vary according to their type, but they can generally be shared across process and API boundaries.

2.4. Application Binary Interface

The mechanism by which Vulkan is made available to applications is platform- or implementation-defined. On many platforms the C interface described in this Specification is provided by a shared library. Since shared libraries can be changed independently of the applications that use them, they present particular compatibility challenges, and this Specification places some requirements on them.

Shared library implementations must use the default Application Binary Interface (ABI) of the standard C compiler for the platform, or provide customized API headers that cause application code to use the implementation's non-default ABI. An ABI in this context means the size, alignment, and layout of C data types; the procedure calling convention; and the naming convention for shared library symbols corresponding to C functions. Customizing the calling convention for a platform is usually accomplished by defining calling convention macros appropriately in vk_platform.h.

On platforms where Vulkan is provided as a shared library, library symbols beginning with “vk” and followed by a digit or uppercase letter are reserved for use by the implementation. Applications which use Vulkan must not provide definitions of these symbols. This allows the Vulkan shared library to be updated with additional symbols for new API versions or extensions without causing symbol conflicts with existing applications.

Shared library implementations should provide library symbols for commands in the highest version of this Specification they support, and for Window System Integration extensions relevant
to the platform. They **may** also provide library symbols for commands defined by additional extensions.

## Note

These requirements and recommendations are intended to allow implementors to take advantage of platform-specific conventions for SDKs, ABIs, library versioning mechanisms, etc. while still minimizing the code changes necessary to port applications or libraries between platforms. Platform vendors, or providers of the *de facto* standard Vulkan shared library for a platform, are encouraged to document what symbols the shared library provides and how it will be versioned when new symbols are added.

Applications **should** only rely on shared library symbols for commands in the minimum core version required by the application. `vkGetInstanceProcAddr` and `vkGetDeviceProcAddr` **should** be used to obtain function pointers for commands in core versions beyond the application’s minimum required version.

### 2.5. Command Syntax and Duration

The Specification describes Vulkan commands as functions or procedures using C99 syntax. Language bindings for other languages such as C++ and JavaScript **may** allow for stricter parameter passing, or object-oriented interfaces.

Vulkan uses the standard C types for the base type of scalar parameters (e.g. types from `<stdint.h>`), with exceptions described below, or elsewhere in the text when appropriate:

- **VkBool32** represents boolean *True* and *False* values, since C does not have a sufficiently portable built-in boolean type:

  ```
typedef uint32_t VkBool32;
  ```

  `VK_TRUE` represents a boolean *True* (integer 1) value, and `VK_FALSE` a boolean *False* (integer 0) value.

  All values returned from a Vulkan implementation in a `VkBool32` will be either `VK_TRUE` or `VK_FALSE`.

  Applications **must** not pass any other values than `VK_TRUE` or `VK_FALSE` into a Vulkan implementation where a `VkBool32` is expected.

- **VkDeviceSize** represents device memory size and offset values:

  ```
typedef uint64_t VkDeviceSize;
  ```

- **VkDeviceAddress** represents device buffer address values:

  ```
typedef uint64_t VkDeviceAddress;
  ```
Commands that create Vulkan objects are of the form `vkCreate*` and take `Vk*CreateInfo` structures with the parameters needed to create the object. These Vulkan objects are destroyed with commands of the form `vkDestroy*`.

The last in-parameter to each command that creates or destroys a Vulkan object is `pAllocator`. The `pAllocator` parameter can be set to a non-NULL value such that allocations for the given object are delegated to an application provided callback; refer to the Memory Allocation chapter for further details.

Commands that allocate Vulkan objects owned by pool objects are of the form `vkAllocate*`, and take `Vk*AllocateInfo` structures. These Vulkan objects are freed with commands of the form `vkFree*`. These objects do not take allocators; if host memory is needed, they will use the allocator that was specified when their parent pool was created.

Commands are recorded into a command buffer by calling API commands of the form `vkCmd*`. Each such command may have different restrictions on where it can be used: in a primary and/or secondary command buffer, inside and/or outside a render pass, and in one or more of the supported queue types. These restrictions are documented together with the definition of each such command.

The *duration* of a Vulkan command refers to the interval between calling the command and its return to the caller.

2.5.1. Lifetime of Retrieved Results

Information is retrieved from the implementation with commands of the form `vkGet*` and `vkEnumerate*`.

Unless otherwise specified for an individual command, the results are invariant; that is, they will remain unchanged when retrieved again by calling the same command with the same parameters, so long as those parameters themselves all remain valid.

2.6. Threading Behavior

Vulkan is intended to provide scalable performance when used on multiple host threads. All commands support being called concurrently from multiple threads, but certain parameters, or components of parameters are defined to be externally synchronized. This means that the caller must guarantee that no more than one thread is using such a parameter at a given time.

More precisely, Vulkan commands use simple stores to update the state of Vulkan objects. A parameter declared as externally synchronized may have its contents updated at any time during the host execution of the command. If two commands operate on the same object and at least one of the commands declares the object to be externally synchronized, then the caller must guarantee not only that the commands do not execute simultaneously, but also that the two commands are separated by an appropriate memory barrier (if needed).
Memory barriers are particularly relevant for hosts based on the ARM CPU architecture, which is more weakly ordered than many developers are accustomed to from x86/x64 programming. Fortunately, most higher-level synchronization primitives (like the pthread library) perform memory barriers as a part of mutual exclusion, so muting Vulkan objects via these primitives will have the desired effect.

Similarly the application must avoid any potential data hazard of application-owned memory that has its ownership temporarily acquired by a Vulkan command. While the ownership of application-owned memory remains acquired by a command the implementation may read the memory at any point, and it may write non-const qualified memory at any point. Parameters referring to non-const qualified application-owned memory are not marked explicitly as externally synchronized in the Specification.

If an application is using deferred host operations in a command, and that operation is successfully deferred, object parameters and application-owned memory passed to that command may be accessed at any time until the deferred operation is complete.

Many object types are immutable, meaning the objects cannot change once they have been created. These types of objects never need external synchronization, except that they must not be destroyed while they are in use on another thread. In certain special cases mutable object parameters are internally synchronized, making external synchronization unnecessary. Any command parameters that are not labeled as externally synchronized are either not mutated by the command or are internally synchronized. Additionally, certain objects related to a command’s parameters (e.g. command pools and descriptor pools) may be affected by a command, and must also be externally synchronized. These implicit parameters are documented as described below.

Parameters of commands that are externally synchronized are listed below.
Externally Synchronized Parameters

- The `instance` parameter in `vkDestroyInstance`
- The `device` parameter in `vkDestroyDevice`
- The `queue` parameter in `vkQueueSubmit`
- The `fence` parameter in `vkQueueSubmit`
- The `queue` parameter in `vkQueueWaitIdle`
- The `memory` parameter in `vkFreeMemory`
- The `memory` parameter in `vkMapMemory`
- The `memory` parameter in `vkUnmapMemory`
- The `buffer` parameter in `vkBindBufferMemory`
- The `image` parameter in `vkBindImageMemory`
- The `queue` parameter in `vkQueueBindSparse`
- The `fence` parameter in `vkQueueBindSparse`
- The `fence` parameter in `vkDestroyFence`
- The `semaphore` parameter in `vkDestroySemaphore`
- The `event` parameter in `vkDestroyEvent`
- The `event` parameter in `vkSetEvent`
- The `event` parameter in `vkResetEvent`
- The `queryPool` parameter in `vkDestroyQueryPool`
- The `buffer` parameter in `vkDestroyBuffer`
- The `bufferView` parameter in `vkDestroyBufferView`
- The `image` parameter in `vkDestroyImage`
- The `imageView` parameter in `vkDestroyImageView`
- The `shaderModule` parameter in `vkDestroyShaderModule`
- The `pipelineCache` parameter in `vkDestroyPipelineCache`
- The `dstCache` parameter in `vkMergePipelineCaches`
- The `pipeline` parameter in `vkDestroyPipeline`
- The `pipelineLayout` parameter in `vkDestroyPipelineLayout`
- The `sampler` parameter in `vkDestroySampler`
- The `descriptorSetLayout` parameter in `vkDestroyDescriptorSetLayout`
- The `descriptorPool` parameter in `vkDestroyDescriptorPool`
- The `descriptorPool` parameter in `vkResetDescriptorPool`
- The `descriptorPool` member of the `pAllocateInfo` parameter in `vkAllocateDescriptorSets`
- The `descriptorPool` parameter in `vkFreeDescriptorSets`
• The framebuffer parameter in vkDestroyFramebuffer
• The renderPass parameter in vkDestroyRenderPass
• The commandPool parameter in vkDestroyCommandPool
• The commandPool parameter in vkResetCommandPool
• The commandPool member of the pAllocateInfo parameter in vkAllocateCommandBuffers
• The commandPool parameter in vkFreeCommandBuffers
• The commandBuffer parameter in vkBeginCommandBuffer
• The commandBuffer parameter in vkEndCommandBuffer
• The commandBuffer parameter in vkResetCommandBuffer
• The commandBuffer parameter in vkCmdBindPipeline
• The commandBuffer parameter in vkCmdSetViewport
• The commandBuffer parameter in vkCmdSetScissor
• The commandBuffer parameter in vkCmdSetLineWidth
• The commandBuffer parameter in vkCmdSetDepthBias
• The commandBuffer parameter in vkCmdSetBlendConstants
• The commandBuffer parameter in vkCmdSetDepthBounds
• The commandBuffer parameter in vkCmdSetStencilCompareMask
• The commandBuffer parameter in vkCmdSetStencilWriteMask
• The commandBuffer parameter in vkCmdSetStencilReference
• The commandBuffer parameter in vkCmdBindDescriptorSets
• The commandBuffer parameter in vkCmdBindIndexBuffer
• The commandBuffer parameter in vkCmdBindVertexBuffers
• The commandBuffer parameter in vkCmdDraw
• The commandBuffer parameter in vkCmdDrawIndexed
• The commandBuffer parameter in vkCmdDrawIndirect
• The commandBuffer parameter in vkCmdDispatch
• The commandBuffer parameter in vkCmdDispatchIndirect
• The commandBuffer parameter in vkCmdCopyBuffer
• The commandBuffer parameter in vkCmdCopyImage
• The commandBuffer parameter in vkCmdBlitImage
• The commandBuffer parameter in vkCmdCopyBufferToImage
• The commandBuffer parameter in vkCmdCopyImageToBuffer
• The commandBuffer parameter in vkCmdUpdateBuffer
• The commandBuffer parameter in vkCmdFillBuffer
The `commandBuffer` parameter in `vkCmdClearColorImage`

The `commandBuffer` parameter in `vkCmdClearDepthStencilImage`

The `commandBuffer` parameter in `vkCmdClearAttachments`

The `commandBuffer` parameter in `vkCmdResolveImage`

The `commandBuffer` parameter in `vkCmdSetEvent`

The `commandBuffer` parameter in `vkCmdResetEvent`

The `commandBuffer` parameter in `vkCmdWaitEvents`

The `commandBuffer` parameter in `vkCmdPipelineBarrier`

The `commandBuffer` parameter in `vkCmdBeginQuery`

The `commandBuffer` parameter in `vkCmdEndQuery`

The `commandBuffer` parameter in `vkCmdResetQueryPool`

The `commandBuffer` parameter in `vkCmdWriteTimestamp`

The `commandBuffer` parameter in `vkCmdCopyQueryPoolResults`

The `commandBuffer` parameter in `vkCmdPushConstants`

The `commandBuffer` parameter in `vkCmdBeginRenderPass`

The `commandBuffer` parameter in `vkCmdNextSubpass`

The `commandBuffer` parameter in `vkCmdEndRenderPass`

The `commandBuffer` parameter in `vkCmdExecuteCommands`

The `surface` parameter in `vkDestroySurfaceKHR`

The `surface` member of the `pCreateInfo` parameter in `vkCreateSwapchainKHR`

The `oldSwapchain` member of the `pCreateInfo` parameter in `vkCreateSwapchainKHR`

The `swapchain` parameter in `vkDestroySwapchainKHR`

The `swapchain` parameter in `vkAcquireNextImageKHR`

The `semaphore` parameter in `vkAcquireNextImageKHR`

The `fence` parameter in `vkAcquireNextImageKHR`

The `queue` parameter in `vkQueuePresentKHR`

The `surface` parameter in `vkGetDeviceGroupSurfacePresentModesKHR`

The `surface` parameter in `vkGetPhysicalDevicePresentRectanglesKHR`

The `display` parameter in `vkCreateDisplayModeKHR`

The `mode` parameter in `vkGetDisplayPlaneCapabilitiesKHR`

The `commandBuffer` parameter in `vkCmdSetDeviceMask`

The `commandBuffer` parameter in `vkCmdSetDeviceMaskKHR`

The `commandBuffer` parameter in `vkCmdDispatchBase`

The `commandBuffer` parameter in `vkCmdDispatchBaseKHR`

The `commandPool` parameter in `vkTrimCommandPool`
• The `commandPool` parameter in `vkTrimCommandPoolKHR`
• The `commandBuffer` parameter in `vkCmdPushDescriptorSetKHR`
• The `commandBuffer` parameter in `vkCmdPushDescriptorSetWithTemplateKHR`
• The `descriptorUpdateTemplate` parameter in `vkDestroyDescriptorUpdateTemplate`
• The `descriptorUpdateTemplate` parameter in `vkDestroyDescriptorUpdateTemplateKHR`
• The `descriptorSet` parameter in `vkUpdateDescriptorSetWithTemplate`
• The `descriptorSet` parameter in `vkUpdateDescriptorSetWithTemplateKHR`
• The `commandBuffer` parameter in `vkCmdBeginRenderPass2`
• The `commandBuffer` parameter in `vkCmdBeginRenderPass2KHR`
• The `commandBuffer` parameter in `vkCmdNextSubpass2`
• The `commandBuffer` parameter in `vkCmdNextSubpass2KHR`
• The `commandBuffer` parameter in `vkCmdEndRenderPass2`
• The `commandBuffer` parameter in `vkCmdEndRenderPass2KHR`
• The `swapchain` parameter in `vkGetSwapchainStatusKHR`
• The `ycbcrConversion` parameter in `vkDestroySamplerYcbcrConversion`
• The `ycbcrConversion` parameter in `vkDestroySamplerYcbcrConversionKHR`
• The `commandBuffer` parameter in `vkCmdDrawIndirectCount`
• The `commandBuffer` parameter in `vkCmdDrawIndirectCountKHR`
• The `commandBuffer` parameter in `vkCmdDrawIndexedIndirectCount`
• The `commandBuffer` parameter in `vkCmdDrawIndexedIndirectCountKHR`
• The `operation` parameter in `vkDestroyDeferredOperationKHR`
• The `callback` parameter in `vkDestroyDebugReportCallbackEXT`
• The `object` member of the `pTagInfo` parameter in `vkDebugMarkerSetObjectTagEXT`
• The `object` member of the `pNameInfo` parameter in `vkDebugMarkerSetObjectNameEXT`
• The `commandBuffer` parameter in `vkCmdBindTransformFeedbackBuffersEXT`
• The `commandBuffer` parameter in `vkCmdBeginTransformFeedbackEXT`
• The `commandBuffer` parameter in `vkCmdEndTransformFeedbackEXT`
• The `commandBuffer` parameter in `vkCmdBeginQueryIndexedEXT`
• The `commandBuffer` parameter in `vkCmdEndQueryIndexedEXT`
• The `commandBuffer` parameter in `vkCmdDrawIndirectByteCountEXT`
• The `commandBuffer` parameter in `vkCmdDrawIndirectCountAMD`
• The `commandBuffer` parameter in `vkCmdDrawIndexedIndirectCountAMD`
• The `commandBuffer` parameter in `vkCmdBeginConditionalRenderingEXT`
• The `commandBuffer` parameter in `vkCmdEndConditionalRenderingEXT`
• The `commandBuffer` parameter in `vkCmdSetViewportWScalingNV`
• The `swapchain` parameter in `vkGetRefreshCycleDurationGOOGLE`  
• The `swapchain` parameter in `vkGetPastPresentationTimingGOOGLE`  
• The `commandBuffer` parameter in `vkCmdSetDiscardRectangleEXT`  
• The `objectHandle` member of the `pNameInfo` parameter in `vkSetDebugUtilsObjectNameEXT`  
• The `objectHandle` member of the `pTagInfo` parameter in `vkSetDebugUtilsObjectTagEXT`  
• The `messenger` parameter in `vkDestroyDebugUtilsMessengerEXT`  
• The `commandBuffer` parameter in `vkCmdSetSampleLocationsEXT`  
• The `validationCache` parameter in `vkDestroyValidationCacheEXT`  
• The `dstCache` parameter in `vkMergeValidationCachesEXT`  
• The `commandBuffer` parameter in `vkCmdBindShadingRateImageNV`  
• The `commandBuffer` parameter in `vkCmdSetViewportShadingRatePaletteNV`  
• The `commandBuffer` parameter in `vkCmdSetCoarseSampleOrderNV`  
• The `accelerationStructure` parameter in `vkDestroyAccelerationStructureKHR`  
• The `accelerationStructure` parameter in `vkDestroyAccelerationStructureNV`  
• The `commandBuffer` parameter in `vkCmdWriteBufferMarkerAMD`  
• The `commandBuffer` parameter in `vkCmdDrawMeshTasksNV`  
• The `commandBuffer` parameter in `vkCmdDrawMeshTasksIndirectNV`  
• The `commandBuffer` parameter in `vkCmdDrawMeshTasksIndirectCountNV`  
• The `commandBuffer` parameter in `vkCmdSetExclusiveScissorNV`  
• The `commandBuffer` parameter in `vkCmdSetLineStippleEXT`  
• The `commandBuffer` parameter in `vkCmdPreprocessGeneratedCommandsNV`  
• The `commandBuffer` parameter in `vkCmdExecuteGeneratedCommandsNV`  
• The `commandBuffer` parameter in `vkCmdBindPipelineShaderGroupNV`  
• The `indirectCommandsLayout` parameter in `vkDestroyIndirectCommandsLayoutNV`  
• The `privateDataSlot` parameter in `vkDestroyPrivateDataSlotEXT`  

For `VkPipelineCache` objects created with flags containing `VK_PIPELINE_CACHE_CREATE_EXTERNALLY_SYNCHRONIZED_BIT_EXT`, the above table is extended with the `pipelineCache` parameter to `vkCreate*Pipelines` being externally synchronized.

There are also a few instances where a command can take in a user allocated list whose contents are externally synchronized parameters. In these cases, the caller must guarantee that at most one thread is using a given element within the list at a given time. These parameters are listed below.
Externally Synchronized Parameter Lists

- The buffer member of each element of the pBufferBinds member of each element of the pBindInfo parameter in vkQueueBindSparse
- The image member of each element of the pImageOpaqueBinds member of each element of the pBindInfo parameter in vkQueueBindSparse
- The image member of each element of the pImageBinds member of each element of the pBindInfo parameter in vkQueueBindSparse
- Each element of the pFences parameter in vkResetFences
- Each element of the pDescriptorSets parameter in vkFreeDescriptorSets
- The dstSet member of each element of the pDescriptorWrites parameter in vkUpdateDescriptorSets
- The dstSet member of each element of the pDescriptorCopies parameter in vkUpdateDescriptorSets
- Each element of the pCommandBuffers parameter in vkFreeCommandBuffers
- Each element of the pWaitSemaphores member of the pPresentInfo parameter in vkQueuePresentKHR
- Each element of the pSwapchains member of the pPresentInfo parameter in vkQueuePresentKHR
- The surface member of each element of the pCreateInfos parameter in vkCreateSharedSwapchainsKHR
- The oldSwapchain member of each element of the pCreateInfos parameter in vkCreateSharedSwapchainsKHR

In addition, there are some implicit parameters that need to be externally synchronized. For example, all commandBuffer parameters that need to be externally synchronized imply that the commandPool that was passed in when creating that command buffer also needs to be externally synchronized. The implicit parameters and their associated object are listed below.
Implicit Externally Synchronized Parameters

- All `VkPhysicalDevice` objects enumerated from `instance` in `vkDestroyInstance`
- All `VkQueue` objects received from `device` in `vkDestroyDevice`
- All `VkQueue` objects created from `device` in `vkDeviceWaitIdle`
- Any `VkDescriptorSet` objects allocated from `descriptorPool` in `vkResetDescriptorPool`
- The `VkCommandPool` that `commandBuffer` was allocated from in `vkBeginCommandBuffer`
- The `VkCommandPool` that `commandBuffer` was allocated from in `vkEndCommandBuffer`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdBindPipeline`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetViewport`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetScissor`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetLineWidth`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetDepthBias`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetBlendConstants`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetDepthBounds`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetStencilCompareMask`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetStencilWriteMask`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetStencilReference`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdBindDescriptorSets`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdBindIndexBuffer`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdBindVertexBuffers`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDraw`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDrawIndexed`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDrawIndirect`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatch`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatchIndirect`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdCopyBuffer`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdCopyImage`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdBlitImage`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdCopyBufferToImage`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdCopyImageToBuffer`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdUpdateBuffer`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdFillBuffer`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdClearColorImage`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdClearDepthStencilImage`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdClearColorImage`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdClearDepthStencilImage`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdClearAttachments`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdResolveImage`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetEvent`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdResetEvent`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdWaitEvents`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdPipelineBarrier`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdBeginQuery`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdEndQuery`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdResetQueryPool`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdWriteTimestamp`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdCopyQueryPoolResults`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdPushConstants`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdBeginRenderPass`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdNextSubpass`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdExecuteCommands`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdSetDeviceMaskKHR`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatchBaseKHR`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatchBaseWithTemplateKHR`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatchBaseWithTemplateKHR`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatchBaseWithTemplateKHR`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatchBaseWithTemplateKHR`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatchBaseWithTemplateKHR`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatchBaseWithTemplateKHR`
- The `VkCommandPool` that `commandBuffer` was allocated from, in `vkCmdDispatchBaseWithTemplateKHR`
• The VkCommandPool that commandBuffer was allocated from, in vkCmdDrawIndexedIndirectCount
• The VkCommandPool that commandBuffer was allocated from, in vkCmdDrawIndexedIndirectCountKHR
• The VkCommandPool that commandBuffer was allocated from, in vkCmdDebugMarkerBeginEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdDebugMarkerEndEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdDebugMarkerInsertEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdBindTransformFeedbackBuffersEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdBeginTransformFeedbackEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdEndTransformFeedbackEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdBeginQueryIndexedEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdEndQueryIndexedEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdDrawIndirectByteCountEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdDrawIndirectCountAMD
• The VkCommandPool that commandBuffer was allocated from, in vkCmdBeginConditionalRenderingEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdEndConditionalRenderingEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdSetViewportWScalingNV
• The VkCommandPool that commandBuffer was allocated from, in vkCmdSetDiscardRectangleEXT
• The VkCommandPool that commandBuffer was allocated from, in vkCmdBeginDebugUtilsLabelEXT

2.7. Errors

Vulkan is a layered API. The lowest layer is the core Vulkan layer, as defined by this Specification. The application can use additional layers above the core for debugging, validation, and other purposes.

One of the core principles of Vulkan is that building and submitting command buffers should be highly efficient. Thus error checking and validation of state in the core layer is minimal, although more rigorous validation can be enabled through the use of layers.

The core layer assumes applications are using the API correctly. Except as documented elsewhere in the Specification, the behavior of the core layer to an application using the API incorrectly is undefined, and may include program termination. However, implementations must ensure that incorrect usage by an application does not affect the integrity of the operating system, the Vulkan implementation, or other Vulkan client applications in the system. In particular, any guarantees made by an operating system about whether memory from one process can be visible to another process or not must not be violated by a Vulkan implementation for any memory allocation. Vulkan implementations are not required to make additional security or integrity guarantees beyond those provided by the OS unless explicitly directed by the application’s use of a particular feature or extension.

Note

For instance, if an operating system guarantees that data in all its memory allocations are set to zero when newly allocated, the Vulkan implementation must make the same guarantees for any allocations it controls (e.g. VkDeviceMemory).

Similarly, if an operating system guarantees that use-after-free of host allocations will not result in values written by another process becoming visible, the same guarantees must be made by the Vulkan implementation for device memory.

Validation of correct API usage is left to validation layers. Applications should be developed with validation layers enabled, to help catch and eliminate errors. Once validated, released applications should not enable validation layers by default.
2.7.1. Valid Usage

Valid usage defines a set of conditions which must be met in order to achieve well-defined runtime behavior in an application. These conditions depend only on Vulkan state, and the parameters or objects whose usage is constrained by the condition.

Some valid usage conditions have dependencies on runtime limits or feature availability. It is possible to validate these conditions against Vulkan’s minimum supported values for these limits and features, or some subset of other known values.

Valid usage conditions do not cover conditions where well-defined behavior (including returning an error code) exists.

Valid usage conditions should apply to the command or structure where complete information about the condition would be known during execution of an application. This is such that a validation layer or linter can be written directly against these statements at the point they are specified.

Note

This does lead to some non-obvious places for valid usage statements. For instance, the valid values for a structure might depend on a separate value in the calling command. In this case, the structure itself will not reference this valid usage as it is impossible to determine validity from the structure that it is invalid - instead this valid usage would be attached to the calling command.

Another example is draw state - the state setters are independent, and can cause a legitimately invalid state configuration between draw calls; so the valid usage statements are attached to the place where all state needs to be valid - at the draw command.

Valid usage conditions are described in a block labelled “Valid Usage” following each command or structure they apply to.

2.7.2. Implicit Valid Usage

Some valid usage conditions apply to all commands and structures in the API, unless explicitly denoted otherwise for a specific command or structure. These conditions are considered implicit, and are described in a block labelled “Valid Usage (Implicit)” following each command or structure they apply to. Implicit valid usage conditions are described in detail below.

Valid Usage for Object Handles

Any input parameter to a command that is an object handle must be a valid object handle, unless otherwise specified. An object handle is valid if:

• It has been created or allocated by a previous, successful call to the API. Such calls are noted in the Specification.

• It has not been deleted or freed by a previous call to the API. Such calls are noted in the Specification.
• Any objects used by that object, either as part of creation or execution, must also be valid.

The reserved values VK_NULL_HANDLE and NULL can be used in place of valid non-dispatchable handles and dispatchable handles, respectively, when explicitly called out in the Specification. Any command that creates an object successfully must not return these values. It is valid to pass these values to vkDestroy* or vkFree* commands, which will silently ignore these values.

Valid Usage for Pointers

Any parameter that is a pointer must be a valid pointer only if it is explicitly called out by a Valid Usage statement.

A pointer is “valid” if it points at memory containing values of the number and type(s) expected by the command, and all fundamental types accessed through the pointer (e.g. as elements of an array or as members of a structure) satisfy the alignment requirements of the host processor.

Valid Usage for Strings

Any parameter that is a pointer to char must be a finite sequence of values terminated by a null character, or if explicitly called out in the Specification, can be NULL.

Valid Usage for Enumerated Types

Any parameter of an enumerated type must be a valid enumerant for that type. A enumerant is valid if:

• The enumerant is defined as part of the enumerated type.
• The enumerant is not the special value (suffixied with _MAX_ENUM) defined for the enumerated type.

1

This special value exists only to ensure that C enum types are 32 bits in size. It is not part of the API, and should not be used by applications.

Any enumerated type returned from a query command or otherwise output from Vulkan to the application must not have a reserved value. Reserved values are values not defined by any extension for that enumerated type.

Note

This language is intended to accommodate cases such as “hidden” extensions known only to driver internals, or layers enabling extensions without knowledge of the application, without allowing return of values not defined by any extension.
Application developers are encouraged to be careful when using `switch` statements with Vulkan API enums. This is because new extensions can add new values to existing enums. The use of a `default:` statement, within a `switch`, may avoid future compilation issues. Particularly for enums like e.g. `VkDriverId` that may change at any time.

### Valid Usage for Flags

A collection of flags is represented by a bitmask using the type `VkFlags`:

```c
typedef uint32_t VkFlags;
```

Bitmasks are passed to many commands and structures to compactly represent options, but `VkFlags` is not used directly in the API. Instead, a `Vk*Flags` type which is an alias of `VkFlags`, and whose name matches the corresponding `Vk*FlagBits` that are valid for that type, is used.

Any `Vk*Flags` member or parameter used in the API as an input must be a valid combination of bit flags. A valid combination is either zero or the bitwise OR of valid bit flags. A bit flag is valid if:

- The bit flag is defined as part of the `Vk*FlagBits` type, where the bits type is obtained by taking the flag type and replacing the trailing `Flags` with `FlagBits`. For example, a flag value of type `VkColorComponentFlags` must contain only bit flags defined by `VkColorComponentFlagBits`.
- The flag is allowed in the context in which it is being used. For example, in some cases, certain bit flags or combinations of bit flags are mutually exclusive.

Any `Vk*Flags` member or parameter returned from a query command or otherwise output from Vulkan to the application may contain bit flags undefined in its corresponding `Vk*FlagBits` type. An application cannot rely on the state of these unspecified bits.

Only the low-order 31 bits (bit positions zero through 30) are available for use as flag bits.

This restriction is due to poorly defined behavior by C compilers given a C enumerant value of `0x80000000`. In some cases adding this enumerant value may increase the size of the underlying `Vk*FlagBits` type, breaking the ABI.

### Valid Usage for Structure Types

Any parameter that is a structure containing a `sType` member must have a value of `sType` which is a valid `VkStructureType` value matching the type of the structure.

Structure types supported by the Vulkan API include:

```c
typedef enum VkStructureType {
    VK_STRUCTURE_TYPE_APPLICATION_INFO = 0,
    VK_STRUCTURE_TYPE_INSTANCE_CREATE_INFO = 1,
    ...
} VkStructureType;
```

Each value corresponds to a particular structure with a sType member with a matching name. As a general rule, the name of each VkStructureType value is obtained by taking the name of the structure, stripping the leading Vk, prefixing each capital letter with _, converting the entire resulting string to upper case, and prefixing it with VK_STRUCTURE_TYPE_. For example, structures of type VkImageCreateInfo correspond to a VkStructureType of VK_STRUCTURE_TYPE_IMAGE_CREATE_INFO, and thus its sType member must equal that when it is passed to the API.

The values VK_STRUCTURE_TYPE_LOADER_INSTANCE_CREATE_INFO and VK_STRUCTURE_TYPE_LOADER_DEVICE_CREATE_INFO are reserved for internal use by the loader, and do not have corresponding Vulkan structures in this Specification.

Valid Usage for Structure Pointer Chains

Any parameter that is a structure containing a void* pNext member must have a value of pNext that is either NULL, or is a pointer to a valid structure defined by an extension, containing sType and pNext.
members as described in the *Vulkan Documentation and Extensions* document in the section “Extension Interactions”. The set of structures connected by *pNext* pointers is referred to as a *pNext chain*. If that extension is supported by the implementation, then it *must* be enabled.

Each type of valid structure *must* not appear more than once in a *pNext* chain, including any *aliases*. This general rule may be explicitly overridden for specific structures.

Any component of the implementation (the loader, any enabled layers, and drivers) *must* skip over, without processing (other than reading the *sType* and *pNext* members) any structures in the chain with *sType* values not defined by extensions supported by that component.

Extension structures are not described in the base Vulkan Specification, but either in layered Specifications incorporating those extensions, or in separate vendor-provided documents.

As a convenience to implementations and layers needing to iterate through a structure pointer chain, the Vulkan API provides two *base structures*. These structures allow for some type safety, and can be used by Vulkan API functions that operate on generic inputs and outputs.

The *VkBaseInStructure* structure is defined as:

```c
typedef struct VkBaseInStructure {
    VkStructureType sType;
    const struct VkBaseInStructure*pNext;
} VkBaseInStructure;
```

- *sType* is the structure type of the structure being iterated through.
- *pNext* is NULL or a pointer to the next structure in a structure chain.

*VkBaseInStructure* can be used to facilitate iterating through a read-only structure pointer chain.

The *VkBaseOutStructure* structure is defined as:

```c
typedef struct VkBaseOutStructure {
    VkStructureType sType;
    struct VkBaseOutStructure* pNext;
} VkBaseOutStructure;
```

- *sType* is the structure type of the structure being iterated through.
- *pNext* is NULL or a pointer to the next structure in a structure chain.

*VkBaseOutStructure* can be used to facilitate iterating through a structure pointer chain that returns data back to the application.

**Valid Usage for Nested Structures**

The above conditions also apply recursively to members of structures provided as input to a command, either as a direct argument to the command, or themselves a member of another structure.
Specifics on valid usage of each command are covered in their individual sections.

**Valid Usage for Extensions**

Instance-level functionality or behavior added by an instance extension to the API must not be used unless that extension is supported by the instance as determined by `vkEnumerateInstanceExtensionProperties`, and that extension is enabled in `VkInstanceCreateInfo`.

Physical-device-level functionality or behavior added by an instance extension to the API must not be used unless that extension is supported by the instance as determined by `vkEnumerateInstanceExtensionProperties`, and that extension is enabled in `VkInstanceCreateInfo`.

Physical-device-level functionality or behavior added by a device extension to the API must not be used unless the conditions described in Extending Physical Device Core Functionality are met.

Device functionality or behavior added by a device extension to the API must not be used unless that extension is supported by the device as determined by `vkEnumerateDeviceExtensionProperties`, and that extension is enabled in `VkDeviceCreateInfo`.

**Valid Usage for Newer Core Versions**

Physical-device-level functionality or behavior added by a new core version of the API must not be used unless it is supported by the physical device as determined by `VkPhysicalDeviceProperties::apiVersion` and the specified version of `VkApplicationInfo::apiVersion`.

Device-level functionality or behavior added by a new core version of the API must not be used unless it is supported by the device as determined by `VkPhysicalDeviceProperties::apiVersion` and the specified version of `VkApplicationInfo::apiVersion`.

**2.7.3. Return Codes**

While the core Vulkan API is not designed to capture incorrect usage, some circumstances still require return codes. Commands in Vulkan return their status via return codes that are in one of two categories:

- Successful completion codes are returned when a command needs to communicate success or status information. All successful completion codes are non-negative values.
- Run time error codes are returned when a command needs to communicate a failure that could only be detected at runtime. All runtime error codes are negative values.

All return codes in Vulkan are reported via `VkResult` return values. The possible codes are:
typedef enum VkResult {
    VK_SUCCESS = 0,
    VK_NOT_READY = 1,
    VK_TIMEOUT = 2,
    VK_EVENT_SET = 3,
    VK_EVENT_RESET = 4,
    VK_INCOMPLETE = 5,

    VK_OPERATION_NOT_DEFERRED_KHR = 1000268003,
    VK_PIPELINE_COMPILE_REQUIRED_EXT = 1000297000,
    VK_ERROR_OUT_OF_POOL_MEMORY_KHR = VK_ERROR_OUT_OF_POOL_MEMORY,
    VK_ERROR_INVALID_EXTERNAL_HANDLE_KHR = VK_ERROR_INVALID_EXTERNAL_HANDLE,
    VK_ERROR_FRAGMENTATION_KHR = VK_ERROR_FRAGMENTATION,
    VK_ERROR_INVALID_DEVICE_ADDRESS_KHR = VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS_KHR =
    VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS,
    VK_ERROR_PIPELINE_COMPILE_REQUIRED_EXT = VK_PIPELINE_COMPILE_REQUIRED_EXT,
} VkResult;

Success Codes
• **VK_SUCCESS** Command successfully completed
• **VK_NOT_READY** A fence or query has not yet completed
• **VK_TIMEOUT** A wait operation has not completed in the specified time
• **VK_EVENT_SET** An event is signaled
• **VK_EVENT_RESET** An event is unsignaled
• **VK_INCOMPLETE** A return array was too small for the result
• **VK_SUBOPTIMAL_KHR** A swapchain no longer matches the surface properties exactly, but can still be used to present to the surface successfully.
• **VK_THREAD_IDLE_KHR** A deferred operation is not complete but there is currently no work for this thread to do at the time of this call.
• **VK_THREAD_DONE_KHR** A deferred operation is not complete but there is no work remaining to assign to additional threads.
• **VK_OPERATION_DEFERRED_KHR** A deferred operation was requested and at least some of the work was deferred.
• **VK_OPERATION_NOT_DEFERRED_KHR** A deferred operation was requested and no operations were deferred.
• **VK_PIPELINE_COMPILE_REQUIRED_EXT** A requested pipeline creation would have required compilation, but the application requested compilation to not be performed.

**Error codes**
• **VK_ERROR_OUT_OF_HOST_MEMORY** A host memory allocation has failed.
• **VK_ERROR_OUT_OF_DEVICE_MEMORY** A device memory allocation has failed.
• **VK_ERROR_INITIALIZATION_FAILED** Initialization of an object could not be completed for implementation-specific reasons.
• **VK_ERROR_DEVICE_LOST** The logical or physical device has been lost. See [Lost Device](#)
• **VK_ERROR_MEMORY_MAP_FAILED** Mapping of a memory object has failed.
• **VK_ERROR_LAYER_NOT_PRESENT** A requested layer is not present or could not be loaded.
• **VK_ERROR_EXTENSION_NOT_PRESENT** A requested extension is not supported.
• **VK_ERROR_FEATURE_NOT_PRESENT** A requested feature is not supported.
• **VK_ERROR_INCOMPATIBLE_DRIVER** The requested version of Vulkan is not supported by the driver or is otherwise incompatible for implementation-specific reasons.
• **VK_ERROR_TOO_MANY_OBJECTS** Too many objects of the type have already been created.
• **VK_ERROR_FORMAT_NOT_SUPPORTED** A requested format is not supported on this device.
• **VK_ERROR_FRAGMENTED_POOL** A pool allocation has failed due to fragmentation of the pool’s memory. This must only be returned if no attempt to allocate host or device memory was made to accommodate the new allocation. This should be returned in preference to **VK_ERROR_OUT_OF_POOL_MEMORY**, but only if the implementation is certain that the pool allocation failure was due to fragmentation.
• **VK_ERROR_SURFACE_LOST_KHR** A surface is no longer available.
• **VK_ERROR_NATIVE_WINDOW_IN_USE_KHR** The requested window is already in use by Vulkan or another API in a manner which prevents it from being used again.

• **VK_ERROR_OUT_OF_DATE_KHR** A surface has changed in such a way that it is no longer compatible with the swapchain, and further presentation requests using the swapchain will fail. Applications **must** query the new surface properties and recreate their swapchain if they wish to continue presenting to the surface.

• **VK_ERROR_INCOMPATIBLE_DISPLAY_KHR** The display used by a swapchain does not use the same presentable image layout, or is incompatible in a way that prevents sharing an image.

• **VK_ERROR_INVALID_SHADER_NV** One or more shaders failed to compile or link. More details are reported back to the application via **VK_EXT_debug_report** if enabled.

• **VK_ERROR_OUT_OF_POOL_MEMORY** A pool memory allocation has failed. This **must** only be returned if no attempt to allocate host or device memory was made to accommodate the new allocation. If the failure was definitely due to fragmentation of the pool, **VK_ERROR_FRAGMENTED_POOL** should be returned instead.

• **VK_ERROR_INVALID_EXTERNAL_HANDLE** An external handle is not a valid handle of the specified type.

• **VK_ERROR_FRAGMENTATION** A descriptor pool creation has failed due to fragmentation.

• **VK_ERROR_INVALID_DEVICE_ADDRESS_EXT** A buffer creation failed because the requested address is not available.

• **VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS** A buffer creation or memory allocation failed because the requested address is not available. A shader group handle assignment failed because the requested shader group handle information is no longer valid.

• **VK_ERROR_FULL_SCREEN_EXCLUSIVE_MODE_LOST_EXT** An operation on a swapchain created with **VK_FULL_SCREEN_EXCLUSIVE_APPLICATION_CONTROLLED_EXT** failed as it did not have exclusive full-screen access. This **may** occur due to implementation-dependent reasons, outside of the application’s control.

• **VK_ERROR_UNKNOWN** An unknown error has occurred; either the application has provided invalid input, or an implementation failure has occurred.

If a command returns a runtime error, unless otherwise specified any output parameters will have undefined contents, except that if the output parameter is a structure with **sType** and **pNext** fields, those fields will be unmodified. Any structures chained from **pNext** will also have undefined contents, except that **sType** and **pNext** will be unmodified.

Out of memory errors do not damage any currently existing Vulkan objects. Objects that have already been successfully created can still be used by the application.

**VK_ERROR_UNKNOWN** will be returned by an implementation when an unexpected error occurs that cannot be attributed to valid behavior of the application and implementation. Under these conditions, it **may** be returned from any command returning a **VkResult**.
Note

\texttt{VK\_ERROR\_UNKNOWN} is not expected to ever be returned if the application behavior is valid, and if the implementation is bug-free. If \texttt{VK\_ERROR\_UNKNOWN} is received, the application should be checked against the latest validation layers to verify correct behavior as much as possible. If no issues are identified it could be an implementation issue, and the implementor should be contacted for support.

Performance-critical commands generally do not have return codes. If a runtime error occurs in such commands, the implementation will defer reporting the error until a specified point. For commands that record into command buffers (\texttt{vkCmd*}) runtime errors are reported by \texttt{vkEndCommandBuffer}.

### 2.8. Numeric Representation and Computation

Implementations normally perform computations in floating-point, and \textbf{must} meet the range and precision requirements defined under “Floating-Point Computation” below.

These requirements only apply to computations performed in Vulkan operations outside of shader execution, such as texture image specification and sampling, and per-fragment operations. Range and precision requirements during shader execution differ and are specified by the \textit{Precision and Operation of SPIR-V Instructions} section.

In some cases, the representation and/or precision of operations is implicitly limited by the specified format of vertex or texel data consumed by Vulkan. Specific floating-point formats are described later in this section.

#### 2.8.1. Floating-Point Computation

Most floating-point computation is performed in SPIR-V shader modules. The properties of computation within shaders are constrained as defined by the \textit{Precision and Operation of SPIR-V Instructions} section.

Some floating-point computation is performed outside of shaders, such as viewport and depth range calculations. For these computations, we do not specify how floating-point numbers are to be represented, or the details of how operations on them are performed, but only place minimal requirements on representation and precision as described in the remainder of this section.

We require simply that numbers’ floating-point parts contain enough bits and that their exponent fields are large enough so that individual results of floating-point operations are accurate to about 1 part in $10^5$. The maximum representable magnitude for all floating-point values \textbf{must} be at least $2^{32}$.

\[
\times 0 = 0 \times x = 0 \text{ for any non-infinite and non-NaN } x.
\]

\[
1 \times x = x \times 1 = x.
\]
$x + 0 = 0 + x = x$.

$0^0 = 1$.

Occasionally, further requirements will be specified. Most single-precision floating-point formats meet these requirements.

The special values Inf and -Inf encode values with magnitudes too large to be represented; the special value NaN encodes “Not A Number” values resulting from undefined arithmetic operations such as $0 / 0$. Implementations may support Inf and NaN in their floating-point computations.

### 2.8.2. Floating-Point Format Conversions

When a value is converted to a defined floating-point representation, finite values falling between two representable finite values are rounded to one or the other. The rounding mode is not defined. Finite values whose magnitude is larger than that of any representable finite value may be rounded either to the closest representable finite value or to the appropriately signed infinity. For unsigned destination formats any negative values are converted to zero. Positive infinity is converted to positive infinity; negative infinity is converted to negative infinity in signed formats and to zero in unsigned formats; and any NaN is converted to a NaN.

### 2.8.3. 16-Bit Floating-Point Numbers

16-bit floating point numbers are defined in the “16-bit floating point numbers” section of the [Khronos Data Format Specification](https://www.khronos.org/registry/ Khronos Data Format Specification).

### 2.8.4. Unsigned 11-Bit Floating-Point Numbers

Unsigned 11-bit floating point numbers are defined in the “Unsigned 11-bit floating point numbers” section of the [Khronos Data Format Specification](https://www.khronos.org/registry/ Khronos Data Format Specification).

### 2.8.5. Unsigned 10-Bit Floating-Point Numbers

Unsigned 10-bit floating point numbers are defined in the “Unsigned 10-bit floating point numbers” section of the [Khronos Data Format Specification](https://www.khronos.org/registry/ Khronos Data Format Specification).

### 2.8.6. General Requirements

Any representable floating-point value in the appropriate format is legal as input to a Vulkan command that requires floating-point data. The result of providing a value that is not a floating-point number to such a command is unspecified, but must not lead to Vulkan interruption or termination. For example, providing a negative zero (where applicable) or a denormalized number to a Vulkan command must yield deterministic results, while providing a NaN or Inf yields unspecified results.

Some calculations require division. In such cases (including implied divisions performed by vector normalization), division by zero produces an unspecified result but must not lead to Vulkan
2.9. Fixed-Point Data Conversions

When generic vertex attributes and pixel color or depth components are represented as integers, they are often (but not always) considered to be normalized. Normalized integer values are treated specially when being converted to and from floating-point values, and are usually referred to as normalized fixed-point.

In the remainder of this section, \( b \) denotes the bit width of the fixed-point integer representation. When the integer is one of the types defined by the API, \( b \) is the bit width of that type. When the integer comes from an image containing color or depth component texels, \( b \) is the number of bits allocated to that component in its specified image format.

The signed and unsigned fixed-point representations are assumed to be \( b \)-bit binary two’s-complement integers and binary unsigned integers, respectively.

2.9.1. Conversion from Normalized Fixed-Point to Floating-Point

Unsigned normalized fixed-point integers represent numbers in the range \([0,1]\). The conversion from an unsigned normalized fixed-point value \( c \) to the corresponding floating-point value \( f \) is defined as

\[
    f = \frac{c}{2^b - 1}
\]

Signed normalized fixed-point integers represent numbers in the range \([-1,1]\). The conversion from a signed normalized fixed-point value \( c \) to the corresponding floating-point value \( f \) is performed using

\[
    f = \max\left(\frac{c}{2^b - 1}, -1.0\right)
\]

Only the range \([-2^{b-1} + 1, 2^{b-1} - 1]\) is used to represent signed fixed-point values in the range \([-1,1]\). For example, if \( b = 8 \), then the integer value -127 corresponds to -1.0 and the value 127 corresponds to 1.0. Note that while zero is exactly expressible in this representation, one value (-128 in the example) is outside the representable range, and must be clamped before use. This equation is used everywhere that signed normalized fixed-point values are converted to floating-point.

2.9.2. Conversion from Floating-Point to Normalized Fixed-Point

The conversion from a floating-point value \( f \) to the corresponding unsigned normalized fixed-point value \( c \) is defined by first clamping \( f \) to the range \([0,1]\), then computing

\[
    c = \text{convertFloatToUint}(f \times (2^b - 1), b)
\]

where \( \text{convertFloatToUint}(r, b) \) returns one of the two unsigned binary integer values with exactly \( b \) bits which are closest to the floating-point value \( r \). Implementations should round to nearest. If \( r \) is equal to an integer, then that integer value must be returned. In particular, if \( f \) is equal to 0.0 or 1.0, then \( c \) must be assigned 0 or \( 2^b - 1 \), respectively.
The conversion from a floating-point value \( f \) to the corresponding signed normalized fixed-point value \( c \) is performed by clamping \( f \) to the range \([-1,1]\), then computing

\[
c = \text{convertFloatToInt}(f \times (2^{b-1} - 1), b)
\]

where \( \text{convertFloatToInt}(r,b) \) returns one of the two signed two's-complement binary integer values with exactly \( b \) bits which are closest to the floating-point value \( r \). Implementations should round to nearest. If \( r \) is equal to an integer, then that integer value must be returned. In particular, if \( f \) is equal to \(-1.0, 0.0, \) or \(1.0\), then \( c \) must be assigned \((-2^{b-1} - 1), 0, \) or \(2^{b-1} - 1\), respectively.

This equation is used everywhere that floating-point values are converted to signed normalized fixed-point.

2.10. Common Object Types

Some types of Vulkan objects are used in many different structures and command parameters, and are described here. These types include offsets, extents, and rectangles.

2.10.1. Offsets

Offsets are used to describe a pixel location within an image or framebuffer, as an \((x,y)\) location for two-dimensional images, or an \((x,y,z)\) location for three-dimensional images.

A two-dimensional offsets is defined by the structure:

```c
typedef struct VkOffset2D {
    int32_t    x;
    int32_t    y;
} VkOffset2D;
```

- \(x\) is the \(x\) offset.
- \(y\) is the \(y\) offset.

A three-dimensional offset is defined by the structure:

```c
typedef struct VkOffset3D {
    int32_t    x;
    int32_t    y;
    int32_t    z;
} VkOffset3D;
```

- \(x\) is the \(x\) offset.
- \(y\) is the \(y\) offset.
- \(z\) is the \(z\) offset.
2.10.2. Extents

Extents are used to describe the size of a rectangular region of pixels within an image or framebuffer, as (width,height) for two-dimensional images, or as (width,height,depth) for three-dimensional images.

A two-dimensional extent is defined by the structure:

```c
typedef struct VkExtent2D {
    uint32_t    width;
    uint32_t    height;
} VkExtent2D;
```

• `width` is the width of the extent.
• `height` is the height of the extent.

A three-dimensional extent is defined by the structure:

```c
typedef struct VkExtent3D {
    uint32_t    width;
    uint32_t    height;
    uint32_t    depth;
} VkExtent3D;
```

• `width` is the width of the extent.
• `height` is the height of the extent.
• `depth` is the depth of the extent.

2.10.3. Rectangles

Rectangles are used to describe a specified rectangular region of pixels within an image or framebuffer. Rectangles include both an offset and an extent of the same dimensionality, as described above. Two-dimensional rectangles are defined by the structure:

```c
typedef struct VkRect2D {
    VkOffset2D    offset;
    VkExtent2D    extent;
} VkRect2D;
```

• `offset` is a `VkOffset2D` specifying the rectangle offset.
• `extent` is a `VkExtent2D` specifying the rectangle extent.
Chapter 3. Initialization

Before using Vulkan, an application must initialize it by loading the Vulkan commands, and creating a VkInstance object.

3.1. Command Function Pointers

Vulkan commands are not necessarily exposed by static linking on a platform. Commands to query function pointers for Vulkan commands are described below.

Note
When extensions are promoted or otherwise incorporated into another extension or Vulkan core version, command aliases may be included. Whilst the behavior of each command alias is identical, the behavior of retrieving each alias’s function pointer is not. A function pointer for a given alias can only be retrieved if the extension or version that introduced that alias is supported and enabled, irrespective of whether any other alias is available.

Function pointers for all Vulkan commands can be obtained with the command:

```c
PFN_vkVoidFunction vkGetInstanceProcAddr( VkInstance instance, const char* pName);
```

- `instance` is the instance that the function pointer will be compatible with, or NULL for commands not dependent on any instance.
- `pName` is the name of the command to obtain.

vkGetInstanceProcAddr itself is obtained in a platform- and loader- specific manner. Typically, the loader library will export this command as a function symbol, so applications can link against the loader library, or load it dynamically and look up the symbol using platform-specific APIs.

The table below defines the various use cases for vkGetInstanceProcAddr and expected return value (“fp” is “function pointer”) for each case.

The returned function pointer is of type PFN_vkVoidFunction, and must be cast to the type of the command being queried before use.

<table>
<thead>
<tr>
<th>instance</th>
<th>pName</th>
<th>return value</th>
</tr>
</thead>
<tbody>
<tr>
<td>*1</td>
<td>NULL</td>
<td>undefined</td>
</tr>
<tr>
<td>invalid non-NULL instance</td>
<td>*1</td>
<td>undefined</td>
</tr>
<tr>
<td>NULL</td>
<td>vkEnumerateInstanceExtensionProperties</td>
<td>fp</td>
</tr>
</tbody>
</table>
### Table

<table>
<thead>
<tr>
<th>instance</th>
<th>pName</th>
<th>return value</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>vkEnumerateInstanceLayerProperties</td>
<td>fp</td>
</tr>
<tr>
<td>NULL</td>
<td>vkCreateInstance</td>
<td>fp</td>
</tr>
<tr>
<td>instance</td>
<td>core Vulkan command</td>
<td>fp^2</td>
</tr>
<tr>
<td>instance</td>
<td>enabled instance extension commands for instance</td>
<td>fp^2</td>
</tr>
<tr>
<td>instance</td>
<td>available device extension commands for instance</td>
<td>fp^3</td>
</tr>
<tr>
<td>any other case, not covered above</td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

1

"*" means any representable value for the parameter (including valid values, invalid values, and NULL).

2

The returned function pointer must only be called with a dispatchable object (the first parameter) that is instance or a child of instance, e.g. VkInstance, VkPhysicalDevice, VkDevice, VkQueue, or VkCommandBuffer.

3

An “available device extension” is a device extension supported by any physical device enumerated by instance.

---

**Valid Usage (Implicit)**

- If instance is not NULL, instance must be a valid VkInstance handle
- pName must be a null-terminated UTF-8 string

In order to support systems with multiple Vulkan implementations, the function pointers returned by vkGetInstanceProcAddr may point to dispatch code that calls a different real implementation for different VkDevice objects or their child objects. The overhead of the internal dispatch for VkDevice objects can be avoided by obtaining device-specific function pointers for any commands that use a device or device-child object as their dispatchable object. Such function pointers can be obtained with the command:

```c
PFN_vkVoidFunction vkGetDeviceProcAddr(
    VkDevice device,
    const char* pName);
```

The table below defines the various use cases for vkGetDeviceProcAddr and expected return value for
each case.

The returned function pointer is of type `PFN_vkVoidFunction`, and must be cast to the type of the command being queried before use. The function pointer must only be called with a dispatchable object (the first parameter) that is device or a child of device.

<table>
<thead>
<tr>
<th>device</th>
<th>fName</th>
<th>return value</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>*1</td>
<td>undefined</td>
</tr>
<tr>
<td>invalid device</td>
<td>*1</td>
<td>undefined</td>
</tr>
<tr>
<td>device</td>
<td>NULL</td>
<td>undefined</td>
</tr>
<tr>
<td>device</td>
<td>core device-level Vulkan command</td>
<td>fp2</td>
</tr>
<tr>
<td>device</td>
<td>enabled extension device-level commands</td>
<td>fp2</td>
</tr>
<tr>
<td>any other case, not covered above</td>
<td></td>
<td>NULL</td>
</tr>
</tbody>
</table>

1

"*" means any representable value for the parameter (including valid values, invalid values, and NULL).

2

The returned function pointer must only be called with a dispatchable object (the first parameter) that is device or a child of device e.g. VkDevice, VkQueue, or VkCommandBuffer.

Valid Usage (Implicit)

- device must be a valid VkDevice handle
- fName must be a null-terminated UTF-8 string

The definition of `PFN_vkVoidFunction` is:

```c
typedef void (VKAPI_PTR *PFN_vkVoidFunction)(void);
```

3.1.1. Extending Physical Device From Device Extensions

When the VK_KHR_get_physical_device_properties2 extension is enabled, physical-device-level functionality of a device extension can be used with a physical device if the corresponding extension is enumerated by `vkEnumerateDeviceExtensionProperties` for that physical device, even before a logical device has been created.

To obtain a function pointer for a physical-device-level command from a device extension, an application can use `vkGetInstanceProcAddr`. This function pointer may point to dispatch code,
which calls a different real implementation for different `VkPhysicalDevice` objects. Applications must not use a `VkPhysicalDevice` in any command added by an extension or core version that is not supported by that physical device.

Device extensions may define structures that can be added to the `pNext` chain of physical-device-level commands.

### 3.2. Instances

There is no global state in Vulkan and all per-application state is stored in a `VkInstance` object. Creating a `VkInstance` object initializes the Vulkan library and allows the application to pass information about itself to the implementation.

Instances are represented by `VkInstance` handles:

```
VK_DEFINE_HANDLE(VkInstance)
```

To create an instance object, call:

```
VkResult vkCreateInstance(
    const VkInstanceCreateInfo* pCreateInfo,
    const VkAllocationCallbacks* pAllocator,
    VkInstance* pInstance);
```

- `pCreateInfo` is a pointer to a `VkInstanceCreateInfo` structure controlling creation of the instance.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
- `pInstance` points a `VkInstance` handle in which the resulting instance is returned.

`vkCreateInstance` verifies that the requested layers exist. If not, `vkCreateInstance` will return `VK_ERROR_LAYER_NOT_PRESENT`. Next `vkCreateInstance` verifies that the requested extensions are supported (e.g. in the implementation or in any enabled instance layer) and if any requested extension is not supported, `vkCreateInstance` must return `VK_ERROR_EXTENSION_NOT_PRESENT`. After verifying and enabling the instance layers and extensions the `VkInstance` object is created and returned to the application. If a requested extension is only supported by a layer, both the layer and the extension need to be specified at `vkCreateInstance` time for the creation to succeed.

**Valid Usage**

- All required extensions for each extension in the `VkInstanceCreateInfo` :::`ppEnabledExtensionNames` list must also be present in that list
Valid Usage (Implicit)

- **pCreateInfo** must be a valid pointer to a valid `VkInstanceCreateInfo` structure.
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid `VkAllocationCallbacks` structure.
- **pInstance** must be a valid pointer to a `VkInstance` handle.

Return Codes

**Success**
- **VK_SUCCESS**

**Failure**
- **VK_ERROR_OUT_OF_HOST_MEMORY**
- **VK_ERROR_OUT_OF_DEVICE_MEMORY**
- **VK_ERROR_INITIALIZATION_FAILED**
- **VK_ERROR_LAYER_NOT_PRESENT**
- **VK_ERROR_EXTENSION_NOT_PRESENT**
- **VK_ERROR_INCOMPATIBLE_DRIVER**

The `VkInstanceCreateInfo` structure is defined as:

```c
typedef struct VkInstanceCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkInstanceCreateFlags flags;
    const VkApplicationInfo* pApplicationInfo;
    uint32_t enabledLayerCount;
    const char* const* ppEnabledLayerNames;
    uint32_t enabledExtensionCount;
    const char* const* ppEnabledExtensionNames;
} VkInstanceCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **flags** is reserved for future use.
- **pApplicationInfo** is NULL or a pointer to a `VkApplicationInfo` structure. If not NULL, this information helps implementations recognize behavior inherent to classes of applications. `VkApplicationInfo` is defined in detail below.
- **enabledLayerCount** is the number of global layers to enable.
• **ppEnabledLayerNames** is a pointer to an array of `enabledLayerCount` null-terminated UTF-8 strings containing the names of layers to enable for the created instance. The layers are loaded in the order they are listed in this array, with the first array element being the closest to the application, and the last array element being the closest to the driver. See the Layers section for further details.

• **enabledExtensionCount** is the number of global extensions to enable.

• **ppEnabledExtensionNames** is a pointer to an array of `enabledExtensionCount` null-terminated UTF-8 strings containing the names of extensions to enable.

---

**Valid Usage (Implicit)**

• **sType** must be `VK_STRUCTURE_TYPE_INSTANCE_CREATE_INFO`

• Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkDebugReportCallbackCreateInfoEXT`, `VkDebugUtilsMessengerCreateInfoEXT`, `VkValidationFeaturesEXT`, or `VkValidationFlagsEXT`

• The `sType` value of each struct in the `pNext` chain must be unique

• **flags** must be `0`

• If `pApplicationInfo` is not `NULL`, `pApplicationInfo` must be a valid pointer to a valid `VkApplicationInfo` structure

• If `enabledLayerCount` is not `0`, `ppEnabledLayerNames` must be a valid pointer to an array of `enabledLayerCount` null-terminated UTF-8 strings

• If `enabledExtensionCount` is not `0`, `ppEnabledExtensionNames` must be a valid pointer to an array of `enabledExtensionCount` null-terminated UTF-8 strings

---

```typedef VkFlags VkInstanceCreateFlags;```

`VkInstanceCreateFlags` is a bitmask type for setting a mask, but is currently reserved for future use.

When creating a Vulkan instance for which you wish to disable validation checks, add a `VkValidationFlagsEXT` structure to the `pNext` chain of the `VkInstanceCreateInfo` structure, specifying the checks to be disabled.

```typedef struct VkValidationFlagsEXT {
    VkStructureType                                    sType;
    const void*                                        pNext;
    uint32_t                                            disabledValidationCheckCount;
    const VkValidationCheckEXT*                        pDisabledValidationChecks;
} VkValidationFlagsEXT;```

• **sType** is the type of this structure.

• **pNext** is `NULL` or a pointer to an extension-specific structure.
• `disabledValidationCheckCount` is the number of checks to disable.

• `pDisabledValidationChecks` is a pointer to an array of `VkValidationCheckEXT` values specifying the validation checks to be disabled.

### Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_VALIDATION_FLAGS_EXT`
- `pDisabledValidationChecks` **must** be a valid pointer to an array of `disabledValidationCheckCount` valid `VkValidationCheckEXT` values
- `disabledValidationCheckCount` **must** be greater than 0

Possible values of elements of the `VkValidationFlagsEXT::pDisabledValidationChecks` array, specifying validation checks to be disabled, are:

```c
typedef enum VkValidationCheckEXT {
    VK_VALIDATION_CHECK_ALL_EXT = 0,
    VK_VALIDATION_CHECK_SHADERS_EXT = 1,
} VkValidationCheckEXT;
```

- `VK_VALIDATION_CHECK_ALL_EXT` specifies that all validation checks are disabled.
- `VK_VALIDATION_CHECK_SHADERS_EXT` specifies that shader validation is disabled.

When creating a Vulkan instance for which you wish to enable or disable specific validation features, add a `VkValidationFeaturesEXT` structure to the `pNext` chain of the `VkInstanceCreateInfo` structure, specifying the features to be enabled or disabled.

```c
typedef struct VkValidationFeaturesEXT {
    VkStructureType                          sType;
    const void*                               pNext;
    uint32_t                                   enabledValidationFeatureCount;
    const VkValidationFeatureEnableEXT*       pEnabledValidationFeatures;
    uint32_t                                   disabledValidationFeatureCount;
    const VkValidationFeatureDisableEXT*      pDisabledValidationFeatures;
} VkValidationFeaturesEXT;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `enabledValidationFeatureCount` is the number of features to enable.
- `pEnabledValidationFeatures` is a pointer to an array of `VkValidationFeatureEnableEXT` values specifying the validation features to be enabled.
- `disabledValidationFeatureCount` is the number of features to disable.
- `pDisabledValidationFeatures` is a pointer to an array of `VkValidationFeatureDisableEXT` values specifying validation features to be disabled.
Specifying the validation features to be disabled.

Valid Usage

- If the `pEnabledValidationFeatures` array contains `VK_VALIDATION_FEATURE_ENABLE_GPU_ASSISTED_RESERVE_BINDING_SLOT_EXT`, then it must also contain `VK_VALIDATION_FEATURE_ENABLE_GPU_ASSISTED_EXT`.
- If the `pEnabledValidationFeatures` array contains `VK_VALIDATION_FEATURE_ENABLE_DEBUG_PRINTF_EXT`, then it must not contain `VK_VALIDATION_FEATURE_ENABLE_GPU_ASSISTED_EXT`.

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_VALIDATION_FEATURES_EXT`.
- If `enabledValidationFeatureCount` is not 0, `pEnabledValidationFeatures` must be a valid pointer to an array of `enabledValidationFeatureCount` valid `VkValidationFeatureEnableEXT` values.
- If `disabledValidationFeatureCount` is not 0, `pDisabledValidationFeatures` must be a valid pointer to an array of `disabledValidationFeatureCount` valid `VkValidationFeatureDisableEXT` values.

Possible values of elements of the `VkValidationFeaturesEXT::pEnabledValidationFeatures` array, specifying validation features to be enabled, are:

```c
typedef enum VkValidationFeatureEnableEXT {
    VK_VALIDATION_FEATURE_ENABLE_GPU_ASSISTED_EXT = 0,
    VK_VALIDATION_FEATURE_ENABLE_GPU_ASSISTED_RESERVE_BINDING_SLOT_EXT = 1,
    VK_VALIDATION_FEATURE_ENABLE_BEST_PRACTICES_EXT = 2,
    VK_VALIDATION_FEATURE_ENABLE_DEBUG_PRINTF_EXT = 3,
} VkValidationFeatureEnableEXT;
```

- `VK_VALIDATION_FEATURE_ENABLE_GPU_ASSISTED_EXT` specifies that GPU-assisted validation is enabled. Activating this feature instruments shader programs to generate additional diagnostic data. This feature is disabled by default.

- `VK_VALIDATION_FEATURE_ENABLE_GPU_ASSISTED_RESERVE_BINDING_SLOT_EXT` specifies that the validation layers reserve a descriptor set binding slot for their own use. The layer reports a value for `VkPhysicalDeviceLimits::maxBoundDescriptorSets` that is one less than the value reported by the device. If the device supports the binding of only one descriptor set, the validation layer does not perform GPU-assisted validation. This feature is disabled by default.

- `VK_VALIDATION_FEATURE_ENABLE_BEST_PRACTICES_EXT` specifies that Vulkan best-practices validation is enabled. Activating this feature enables the output of warnings related to common misuse of the API, but which are not explicitly prohibited by the specification. This feature is disabled by default.
• **VK_VALIDATION_FEATURE_ENABLE_DEBUG_PRINTF_EXT** specifies that the layers will process `debugPrintfEXT` operations in shaders and send the resulting output to the debug callback. This feature is disabled by default.

Possible values of elements of the `VkValidationFeaturesEXT::pDisabledValidationFeatures` array, specifying validation features to be disabled, are:

```c
typedef enum VkValidationFeatureDisableEXT {
    VK_VALIDATION_FEATURE_DISABLE_ALL_EXT = 0,
    VK_VALIDATION_FEATURE_DISABLE_SHADERS_EXT = 1,
    VK_VALIDATION_FEATURE_DISABLE_THREAD_SAFETY_EXT = 2,
    VK_VALIDATION_FEATURE_DISABLE_API_PARAMETERS_EXT = 3,
    VK_VALIDATION_FEATURE_DISABLE_OBJECT_LIFETIMES_EXT = 4,
    VK_VALIDATION_FEATURE_DISABLE_CORE_CHECKS_EXT = 5,
    VK_VALIDATION_FEATURE_DISABLE_UNIQUE_HANDLES_EXT = 6,
} VkValidationFeatureDisableEXT;
```

• **VK_VALIDATION_FEATURE_DISABLE_ALL_EXT** specifies that all validation checks are disabled.

• **VK_VALIDATION_FEATURE_DISABLE_SHADERS_EXT** specifies that shader validation is disabled. This feature is enabled by default.

• **VK_VALIDATION_FEATURE_DISABLE_THREAD_SAFETY_EXT** specifies that thread safety validation is disabled. This feature is enabled by default.

• **VK_VALIDATION_FEATURE_DISABLE_API_PARAMETERS_EXT** specifies that stateless parameter validation is disabled. This feature is enabled by default.

• **VK_VALIDATION_FEATURE_DISABLE_OBJECT_LIFETIMES_EXT** specifies that object lifetime validation is disabled. This feature is enabled by default.

• **VK_VALIDATION_FEATURE_DISABLE_CORE_CHECKS_EXT** specifies that core validation checks are disabled. This feature is enabled by default. If this feature is disabled, the shader validation and GPU-assisted validation features are also disabled.

• **VK_VALIDATION_FEATURE_DISABLE_UNIQUE_HANDLES_EXT** specifies that protection against duplicate non-dispatchable object handles is disabled. This feature is enabled by default.

**Note**

Disabling checks such as parameter validation and object lifetime validation prevents the reporting of error conditions that can cause other validation checks to behave incorrectly or crash. Some validation checks assume that their inputs are already valid and do not always revalidate them.

**Note**

The `VK_EXT_validation_features` extension subsumes all the functionality provided in the `VK_EXT_validation_flags` extension.

The `VkApplicationInfo` structure is defined as:
typedef struct VkApplicationInfo {
    VkStructureType sType;
    const void* pNext;
    const char* pApplicationName;
    uint32_t applicationVersion;
    const char* pEngineName;
    uint32_t engineVersion;
    uint32_t apiVersion;
} VkApplicationInfo;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• pApplicationName is NULL or is a pointer to a null-terminated UTF-8 string containing the name of the application.
• applicationVersion is an unsigned integer variable containing the developer-supplied version number of the application.
• pEngineName is NULL or is a pointer to a null-terminated UTF-8 string containing the name of the engine (if any) used to create the application.
• engineVersion is an unsigned integer variable containing the developer-supplied version number of the engine used to create the application.
• apiVersion is the version of the Vulkan API against which the application expects to run, encoded as described in Version Numbers. If apiVersion is 0 the implementation must ignore it, otherwise if the implementation does not support the requested apiVersion, or an effective substitute for apiVersion, it must return VK_ERROR_INCOMPATIBLE_DRIVER. The patch version number specified in apiVersion is ignored when creating an instance object. Only the major and minor versions of the instance must match those requested in apiVersion.

Valid Usage

• If apiVersion is not 0, then it must be greater or equal to VK_API_VERSION_1_0

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_APPLICATION_INFO
• pNext must be NULL
• If pApplicationName is not NULL, pApplicationName must be a null-terminated UTF-8 string
• If pEngineName is not NULL, pEngineName must be a null-terminated UTF-8 string

To destroy an instance, call:
void vkDestroyInstance(
    VkInstance instance,
    const VkAllocationCallbacks* pAllocator);

• **instance** is the handle of the instance to destroy.
• **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.

### Valid Usage

- All child objects created using **instance** must have been destroyed prior to destroying **instance**
- If **VkAllocationCallbacks** were provided when **instance** was created, a compatible set of callbacks **must** be provided here
- If no **VkAllocationCallbacks** were provided when **instance** was created, **pAllocator** must be **NULL**

### Valid Usage (Implicit)

- If **instance** is not **NULL**, **instance** must be a valid **VkInstance** handle
- If **pAllocator** is not **NULL**, **pAllocator** must be a valid pointer to a valid **VkAllocationCallbacks** structure

### Host Synchronization

- Host access to **instance** must be externally synchronized
- Host access to all **VkPhysicalDevice** objects enumerated from **instance** must be externally synchronized
Chapter 4. Devices and Queues

Once Vulkan is initialized, devices and queues are the primary objects used to interact with a Vulkan implementation.

Vulkan separates the concept of physical and logical devices. A physical device usually represents a single complete implementation of Vulkan (excluding instance-level functionality) available to the host, of which there are a finite number. A logical device represents an instance of that implementation with its own state and resources independent of other logical devices.

Physical devices are represented by VkPhysicalDevice handles:

```c
VK_DEFINE_HANDLE(VkPhysicalDevice)
```

4.1. Physical Devices

To retrieve a list of physical device objects representing the physical devices installed in the system, call:

```c
VkResult vkEnumeratePhysicalDevices(
    VkInstance instance,
    uint32_t* pPhysicalDeviceCount,
    VkPhysicalDevice* pPhysicalDevices);
```

- `instance` is a handle to a Vulkan instance previously created with `vkCreateInstance`.
- `pPhysicalDeviceCount` is a pointer to an integer related to the number of physical devices available or queried, as described below.
- `pPhysicalDevices` is either `NULL` or a pointer to an array of `VkPhysicalDevice` handles.

If `pPhysicalDevices` is `NULL`, then the number of physical devices available is returned in `pPhysicalDeviceCount`. Otherwise, `pPhysicalDeviceCount` must point to a variable set by the user to the number of elements in the `pPhysicalDevices` array, and on return the variable is overwritten with the number of handles actually written to `pPhysicalDevices`. If `pPhysicalDeviceCount` is less than the number of physical devices available, `VK_INCOMPLETE` will be returned instead of `VK_SUCCESS`, to indicate that not all the available physical devices were returned.
Valid Usage (Implicit)

- `instance` **must** be a valid `VkInstance` handle
- `pPhysicalDeviceCount` **must** be a valid pointer to a `uint32_t` value
- If the value referenced by `pPhysicalDeviceCount` is not 0, and `pPhysicalDevices` is not NULL, `pPhysicalDevices` **must** be a valid pointer to an array of `pPhysicalDeviceCount` `VkPhysicalDevice` handles

Return Codes

**Success**

- `VK_SUCCESS`
- `VK_INCOMPLETE`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`
- `VK_ERROR_INITIALIZATION_FAILED`

To query general properties of physical devices once enumerated, call:

```c
void vkGetPhysicalDeviceProperties(
    VkPhysicalDevice                                     physicalDevice,
    VkPhysicalDeviceProperties*                         pProperties);
```

- `physicalDevice` is the handle to the physical device whose properties will be queried.
- `pProperties` is a pointer to a `VkPhysicalDeviceProperties` structure in which properties are returned.

Valid Usage (Implicit)

- `physicalDevice` **must** be a valid `VkPhysicalDevice` handle
- `pProperties` **must** be a valid pointer to a `VkPhysicalDeviceProperties` structure

The `VkPhysicalDeviceProperties` structure is defined as:
typedef struct VkPhysicalDeviceProperties {
    uint32_t apiVersion;
    uint32_t driverVersion;
    uint32_t vendorID;
    uint32_t deviceID;
    VkPhysicalDeviceType deviceType;
    char deviceName[VK_MAX_PHYSICAL_DEVICE_NAME_SIZE];
    uint8_t pipelineCacheUUID[VK_UUID_SIZE];
    VkPhysicalDeviceLimits limits;
    VkPhysicalDeviceSparseProperties sparseProperties;
} VkPhysicalDeviceProperties;

- **apiVersion** is the version of Vulkan supported by the device, encoded as described in Version Numbers.
- **driverVersion** is the vendor-specified version of the driver.
- **vendorID** is a unique identifier for the vendor (see below) of the physical device.
- **deviceID** is a unique identifier for the physical device among devices available from the vendor.
- **deviceType** is a VkPhysicalDeviceType specifying the type of device.
- **deviceName** is an array of VK_MAX_PHYSICAL_DEVICE_NAME_SIZE char containing a null-terminated UTF-8 string which is the name of the device.
- **pipelineCacheUUID** is an array of VK_UUID_SIZE uint8_t values representing a universally unique identifier for the device.
- **limits** is the VkPhysicalDeviceLimits structure specifying device-specific limits of the physical device. See Limits for details.
- **sparseProperties** is the VkPhysicalDeviceSparseProperties structure specifying various sparse related properties of the physical device. See Sparse Properties for details.

The **vendorID** and **deviceID** fields are provided to allow applications to adapt to device characteristics that are not adequately exposed by other Vulkan queries.

**Note**

These may include performance profiles, hardware errata, or other characteristics.

The **vendor** identified by **vendorID** is the entity responsible for the most salient characteristics of the underlying implementation of the VkPhysicalDevice being queried.

**Note**

For example, in the case of a discrete GPU implementation, this should be the GPU chipset vendor. In the case of a hardware accelerator integrated into a system-on-chip (SoC), this should be the supplier of the silicon IP used to create the accelerator.

If the vendor has a PCI vendor ID, the low 16 bits of **vendorID** must contain that PCI vendor ID, and
the remaining bits must be set to zero. Otherwise, the value returned must be a valid Khronos vendor ID, obtained as described in the Vulkan Documentation and Extensions: Procedures and Conventions document in the section “Registering a Vendor ID with Khronos”. Khronos vendor IDs are allocated starting at 0x10000, to distinguish them from the PCI vendor ID namespace. Khronos vendor IDs are symbolically defined in the VkVendorId type.

The vendor is also responsible for the value returned in deviceID. If the implementation is driven primarily by a PCI device with a PCI device ID, the low 16 bits of deviceID must contain that PCI device ID, and the remaining bits must be set to zero. Otherwise, the choice of what values to return may be dictated by operating system or platform policies - but should uniquely identify both the device version and any major configuration options (for example, core count in the case of multicore devices).

Note
The same device ID should be used for all physical implementations of that device version and configuration. For example, all uses of a specific silicon IP GPU version and configuration should use the same device ID, even if those uses occur in different SoCs.

Khronos vendor IDs which may be returned in VkPhysicalDeviceProperties::vendorID are:

```c
typedef enum VkVendorId {
    VK_VENDOR_ID_VIV = 0x10001,
    VK_VENDOR_ID_VSI = 0x10002,
    VK_VENDOR_ID_KAZAN = 0x10003,
    VK_VENDOR_ID_CODEPLAY = 0x10004,
    VK_VENDOR_ID_MESA = 0x10005,
} VkVendorId;
```

Note
Khronos vendor IDs may be allocated by vendors at any time. Only the latest canonical versions of this Specification, of the corresponding vk.xml API Registry, and of the corresponding vulkan_core.h header file must contain all reserved Khronos vendor IDs.

Only Khronos vendor IDs are given symbolic names at present. PCI vendor IDs returned by the implementation can be looked up in the PCI-SIG database.

The physical device types which may be returned in VkPhysicalDeviceProperties::deviceType are:
typedef enum VkPhysicalDeviceType {
    VK_PHYSICAL_DEVICE_TYPE_OTHER = 0,
    VK_PHYSICAL_DEVICE_TYPE_INTEGRATED_GPU = 1,
    VK_PHYSICAL_DEVICE_TYPE_DISCRETE_GPU = 2,
    VK_PHYSICAL_DEVICE_TYPE_VIRTUAL_GPU = 3,
    VK_PHYSICAL_DEVICE_TYPE_CPU = 4,
} VkPhysicalDeviceType;

- **VK_PHYSICAL_DEVICE_TYPE_OTHER** - the device does not match any other available types.
- **VK_PHYSICAL_DEVICE_TYPE_INTEGRATED_GPU** - the device is typically one embedded in or tightly coupled with the host.
- **VK_PHYSICAL_DEVICE_TYPE_DISCRETE_GPU** - the device is typically a separate processor connected to the host via an interlink.
- **VK_PHYSICAL_DEVICE_TYPE_VIRTUAL_GPU** - the device is typically a virtual node in a virtualization environment.
- **VK_PHYSICAL_DEVICE_TYPE_CPU** - the device is typically running on the same processors as the host.

The physical device type is advertised for informational purposes only, and does not directly affect the operation of the system. However, the device type may correlate with other advertised properties or capabilities of the system, such as how many memory heaps there are.

To query general properties of physical devices once enumerated, call:

```c
void vkGetPhysicalDeviceProperties2KHR(
    VkPhysicalDevice physicalDevice,    
    VkPhysicalDeviceProperties2* pProperties);
```

- **physicalDevice** is the handle to the physical device whose properties will be queried.
- **pProperties** is a pointer to a VkPhysicalDeviceProperties2 structure in which properties are returned.

Each structure in pProperties and its pNext chain contain members corresponding to properties or implementation-dependent limits. vkGetPhysicalDeviceProperties2 writes each member to a value indicating the value of that property or limit.

**Valid Usage (Implicit)**

- **physicalDevice** must be a valid VkPhysicalDevice handle
- **pProperties** must be a valid pointer to a VkPhysicalDeviceProperties2 structure

The VkPhysicalDeviceProperties2 structure is defined as:
typedef struct VkPhysicalDeviceProperties2 {
    VkStructureType sType;
    void* pNext;
    VkPhysicalDeviceProperties properties;
} VkPhysicalDeviceProperties2;

or the equivalent

typedef VkPhysicalDeviceProperties2 VkPhysicalDeviceProperties2KHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **properties** is a VkPhysicalDeviceProperties structure describing properties of the physical device. This structure is written with the same values as if it were written by vkGetPhysicalDeviceProperties.

The **pNext** chain of this structure is used to extend the structure with properties defined by extensions.
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_PHYSICAL_DEVICE_PROPERTIES_2`
- Each **pNext** member of any structure (including this one) in the **pNext** chain must be either `NULL` or a pointer to a valid instance of
  - `VkPhysicalDeviceBlendOperationAdvancedPropertiesEXT`
  - `VkPhysicalDeviceConservativeRasterizationPropertiesEXT`
  - `VkPhysicalDeviceCooperativeMatrixPropertiesNV`
  - `VkPhysicalDeviceCustomBorderColorPropertiesEXT`
  - `VkPhysicalDeviceDepthStencilResolveProperties`
  - `VkPhysicalDeviceDescriptorIndexingProperties`
  - `VkPhysicalDeviceDeviceGeneratedCommandsPropertiesNV`
  - `VkPhysicalDeviceDiscardRectanglePropertiesEXT`
  - `VkPhysicalDeviceDriverProperties`
  - `VkPhysicalDeviceExternalMemoryHostPropertiesEXT`
  - `VkPhysicalDeviceFloatControlsProperties`
  - `VkPhysicalDeviceFragmentDensityMapPropertiesEXT`
  - `VkPhysicalDeviceIDProperties`
  - `VkPhysicalDeviceInlineUniformBlockPropertiesEXT`
  - `VkPhysicalDeviceLineRasterizationPropertiesEXT`
  - `VkPhysicalDeviceMaintenance3Properties`
  - `VkPhysicalDeviceMeshShaderPropertiesNV`
  - `VkPhysicalDeviceMultiplePerViewAttributesPropertiesNVX`
  - `VkPhysicalDeviceMultiviewProperties`
  - `VkPhysicalDevicePCIBusInfoPropertiesEXT`
  - `VkPhysicalDevicePerformanceQueryPropertiesKHR`
  - `VkPhysicalDevicePointClippingProperties`
  - `VkPhysicalDevicePushDescriptorPropertiesKHR`
  - `VkPhysicalDeviceRayTracingPropertiesKHR`
  - `VkPhysicalDeviceRayTracingPropertiesNV`
  - `VkPhysicalDeviceRobustness2PropertiesEXT`
  - `VkPhysicalDeviceSampleLocationsPropertiesEXT`
  - `VkPhysicalDeviceSamplerFilterMinmaxProperties`
  - `VkPhysicalDeviceShaderCoreProperties2AMD`
  - `VkPhysicalDeviceShaderCorePropertiesAMD`
  - `VkPhysicalDeviceShaderSMBuiltinsPropertiesNV`
  - `VkPhysicalDeviceShadingRateImagePropertiesNV`
  - `VkPhysicalDeviceSubgroupSizeControlPropertiesEXT`
  - `VkPhysicalDeviceTexelBufferAlignmentPropertiesEXT`
  - `VkPhysicalDeviceTimelineSemaphoreProperties`
  - `VkPhysicalDeviceTransformFeedbackPropertiesEXT`
  - `VkPhysicalDeviceVertexAttributeDivisorPropertiesEXT`

- The **sType** value of each struct in the **pNext** chain must be unique

To query the UUID and LUID of a device, add a `VkPhysicalDeviceIDProperties` structure to the **pNext** chain of the `VkPhysicalDeviceProperties2` structure. The `VkPhysicalDeviceIDProperties` structure is defined as:
typedef struct VkPhysicalDeviceIDProperties {
    VkStructureType sType;
    void* pNext;
    uint8_t deviceUUID[VK_UUID_SIZE];
    uint8_t driverUUID[VK_UUID_SIZE];
    uint8_t deviceLUID[VK_LUID_SIZE];
    uint32_t deviceNodeMask;
    VkBool32 deviceLUIDValid;
} VkPhysicalDeviceIDProperties;

or the equivalent

typedef VkPhysicalDeviceIDProperties VkPhysicalDeviceIDPropertiesKHR;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• deviceUUID is an array of VK_UUID_SIZE uint8_t values representing a universally unique identifier for the device.
• driverUUID is an array of VK_UUID_SIZE uint8_t values representing a universally unique identifier for the driver build in use by the device.
• deviceLUID is an array of VK_LUID_SIZE uint8_t values representing a locally unique identifier for the device.
• deviceNodeMask is a uint32_t bitfield identifying the node within a linked device adapter corresponding to the device.
• deviceLUIDValid is a boolean value that will be VK_TRUE if deviceLUID contains a valid LUID and deviceNodeMask contains a valid node mask, and VK_FALSE if they do not.

deviceUUID must be immutable for a given device across instances, processes, driver APIs, driver versions, and system reboots.

Applications can compare the driverUUID value across instance and process boundaries, and can make similar queries in external APIs to determine whether they are capable of sharing memory objects and resources using them with the device.

deviceUUID and/or driverUUID must be used to determine whether a particular external object can be shared between driver components, where such a restriction exists as defined in the compatibility table for the particular object type:

• External memory handle types compatibility
• External semaphore handle types compatibility
• External fence handle types compatibility

If deviceLUIDValid is VK_FALSE, the values of deviceLUID and deviceNodeMask are undefined. If deviceLUIDValid is VK_TRUE and Vulkan is running on the Windows operating system, the contents of
deviceLUID can be cast to an LUID object and must be equal to the locally unique identifier of an IDXGIAdapter1 object that corresponds to physicalDevice. If deviceLUIDValid is VK_TRUE, deviceNodeMask must contain exactly one bit. If Vulkan is running on an operating system that supports the Direct3D 12 API and physicalDevice corresponds to an individual device in a linked device adapter, deviceNodeMask identifies the Direct3D 12 node corresponding to physicalDevice. Otherwise, deviceNodeMask must be 1.

**Note**

Although they have identical descriptions, VkPhysicalDeviceIDProperties::deviceUUID may differ from VkPhysicalDeviceProperties2::pipelineCacheUUID. The former is intended to identify and correlate devices across API and driver boundaries, while the latter is used to identify a compatible device and driver combination to use when serializing and de-serializing pipeline state.

**Note**

While VkPhysicalDeviceIDProperties::deviceUUID is specified to remain consistent across driver versions and system reboots, it is not intended to be usable as a serializable persistent identifier for a device. It may change when a device is physically added to, removed from, or moved to a different connector in a system while that system is powered down. Further, there is no reasonable way to verify with conformance testing that a given device retains the same UUID in a given system across all driver versions supported in that system. While implementations should make every effort to report consistent device UUIDs across driver versions, applications should avoid relying on the persistence of this value for uses other than identifying compatible devices for external object sharing purposes.

**Valid Usage (Implicit)**

- sType must be VK_STRUCTURE_TYPE_PHYSICAL_DEVICE_ID_PROPERTIES

To query the properties of the driver corresponding to a physical device, add a VkPhysicalDeviceDriverProperties structure to the pNext chain of the VkPhysicalDeviceProperties2 structure. The VkPhysicalDeviceDriverProperties structure is defined as:

```c
typedef struct VkPhysicalDeviceDriverProperties {
    VkStructureType sType;
    void* pNext;
    VkDriverId driverID;
    char driverName[VK_MAX_DRIVER_NAME_SIZE];
    char driverInfo[VK_MAX_DRIVER_INFO_SIZE];
    VkConformanceVersion conformanceVersion;
} VkPhysicalDeviceDriverProperties;
```

or the equivalent
typedef VkPhysicalDeviceDriverProperties VkPhysicalDeviceDriverPropertiesKHR;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension specific structure.
- `driverID` is a unique identifier for the driver of the physical device.
- `driverName` is an array of `VK_MAX_DRIVER_NAME_SIZE` `char` containing a null-terminated UTF-8 string which is the name of the driver.
- `driverInfo` is an array of `VK_MAX_DRIVER_INFO_SIZE` `char` containing a null-terminated UTF-8 string with additional information about the driver.
- `conformanceVersion` is the version of the Vulkan conformance test this driver is conformant against (see `VkConformanceVersion`).

`driverID` must be immutable for a given driver across instances, processes, driver versions, and system reboots.

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_PHYSICAL_DEVICE_DRIVER_PROPERTIES`

Khronos driver IDs which may be returned in `VkPhysicalDeviceDriverProperties::driverID` are:
typedef enum VkDriverId {
    VK_DRIVER_ID_AMD_PROPRIETARY = 1,
    VK_DRIVER_ID_AMD_OPEN_SOURCE = 2,
    VK_DRIVER_ID_MESA_RADV = 3,
    VK_DRIVER_ID_NVIDIA_PROPRIETARY = 4,
    VK_DRIVER_ID_INTEL_PROPRIETARY_WINDOWS = 5,
    VK_DRIVER_ID_INTEL_OPEN_SOURCE_MESA = 6,
    VK_DRIVER_ID_IMAGINATION_PROPRIETARY = 7,
    VK_DRIVER_ID_QUALCOMM_PROPRIETARY = 8,
    VK_DRIVER_ID_ARM_PROPRIETARY = 9,
    VK_DRIVER_ID_GOOGLE_SWIFTSHADER = 10,
    VK_DRIVER_ID_GGP_PROPRIETARY = 11,
    VK_DRIVER_ID_BROADCOM_PROPRIETARY = 12,
    VK_DRIVER_ID_MESA_LLVMPIPE = 13,
    VK_DRIVER_ID_AMD_PROPRIETARY_KHR = VK_DRIVER_ID_AMD_PROPRIETARY,
    VK_DRIVER_ID_AMD_OPEN_SOURCE_KHR = VK_DRIVER_ID_AMD_OPEN_SOURCE,
    VK_DRIVER_ID_MESA_RADV_KHR = VK_DRIVER_ID_MESA_RADV,
    VK_DRIVER_ID_NVIDIA_PROPRIETARY_KHR = VK_DRIVER_ID_NVIDIA_PROPRIETARY,
    VK_DRIVER_ID_INTEL_PROPRIETARY_WINDOWS_KHR = VK_DRIVER_ID_INTEL_PROPRIETARY_WINDOWS,
    VK_DRIVER_ID_INTEL_OPEN_SOURCE_MESA_KHR = VK_DRIVER_ID_INTEL_OPEN_SOURCE_MESA,
    VK_DRIVER_ID_IMAGINATION_PROPRIETARY_KHR = VK_DRIVER_ID_IMAGINATION_PROPRIETARY,
    VK_DRIVER_ID_QUALCOMM_PROPRIETARY_KHR = VK_DRIVER_ID_QUALCOMM_PROPRIETARY,
    VK_DRIVER_ID_ARM_PROPRIETARY_KHR = VK_DRIVER_ID_ARM_PROPRIETARY,
    VK_DRIVER_ID_GOOGLE_SWIFTSHADER_KHR = VK_DRIVER_ID_GOOGLE_SWIFTSHADER,
    VK_DRIVER_ID_GGP_PROPRIETARY_KHR = VK_DRIVER_ID_GGP_PROPRIETARY,
    VK_DRIVER_ID_BROADCOM_PROPRIETARY_KHR = VK_DRIVER_ID_BROADCOM_PROPRIETARY,
} VkDriverId;

or the equivalent

typedef VkDriverId VkDriverIdKHR;

Note

Khronos driver IDs may be allocated by vendors at any time. There may be multiple driver IDs for the same vendor, representing different drivers (for e.g. different platforms, proprietary or open source, etc.). Only the latest canonical versions of this Specification, of the corresponding vk.xml API Registry, and of the corresponding vulkan_core.h header file must contain all reserved Khronos driver IDs.

Only driver IDs registered with Khronos are given symbolic names. There may be unregistered driver IDs returned.

The conformance test suite version an implementation is compliant with is described with the VkConformanceVersion structure:
typedef struct VkConformanceVersion {
    uint8_t    major;
    uint8_t    minor;
    uint8_t    subminor;
    uint8_t    patch;
} VkConformanceVersion;

or the equivalent

typedef VkConformanceVersion VkConformanceVersionKHR;

• major is the major version number of the conformance test suite.
• minor is the minor version number of the conformance test suite.
• subminor is the subminor version number of the conformance test suite.
• patch is the patch version number of the conformance test suite.

To query the PCI bus information of a physical device, add a
VkPhysicalDevicePCIBusInfoPropertiesEXT structure to the pNext chain of the
VkPhysicalDeviceProperties2 structure. The VkPhysicalDevicePCIBusInfoPropertiesEXT structure is
defined as:

typedef struct VkPhysicalDevicePCIBusInfoPropertiesEXT {
    VkStructureType    sType;
    void*              pNext;
    uint32_t           pciDomain;
    uint32_t           pciBus;
    uint32_t           pciDevice;
    uint32_t          pciFunction;
} VkPhysicalDevicePCIBusInfoPropertiesEXT;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• pciDomain is the PCI bus domain.
• pciBus is the PCI bus identifier.
• pciDevice is the PCI device identifier.
• pciFunction is the PCI device function identifier.

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_PHYSICAL_DEVICE_PCI_BUS_INFO_PROPERTIES_EXT

To query properties of queues available on a physical device, call:
void vkGetPhysicalDeviceQueueFamilyProperties(
    VkPhysicalDevice physicalDevice,
    uint32_t* pQueueFamilyPropertyCount,
    VkQueueFamilyProperties* pQueueFamilyProperties);

- **physicalDevice** is the handle to the physical device whose properties will be queried.
- **pQueueFamilyPropertyCount** is a pointer to an integer related to the number of queue families available or queried, as described below.
- **pQueueFamilyProperties** is either **NULL** or a pointer to an array of **VkQueueFamilyProperties** structures.

If **pQueueFamilyProperties** is **NULL**, then the number of queue families available is returned in **pQueueFamilyPropertyCount**. Implementations **must** support at least one queue family. Otherwise, **pQueueFamilyPropertyCount** **must** point to a variable set by the user to the number of elements in the **pQueueFamilyProperties** array, and on return the variable is overwritten with the number of structures actually written to **pQueueFamilyProperties**. If **pQueueFamilyPropertyCount** is less than the number of queue families available, at most **pQueueFamilyPropertyCount** structures will be written.

### Valid Usage (Implicit)

- **physicalDevice** **must** be a valid **VkPhysicalDevice** handle
- **pQueueFamilyPropertyCount** **must** be a valid pointer to a **uint32_t** value
- If the value referenced by **pQueueFamilyPropertyCount** is not **0**, and **pQueueFamilyProperties** is not **NULL**, **pQueueFamilyProperties** **must** be a valid pointer to an array of **VkQueueFamilyProperties** structures

The **VkQueueFamilyProperties** structure is defined as:

```c
typedef struct VkQueueFamilyProperties {
    VkQueueFlags queueFlags;
    uint32_t queueCount;
    uint32_t timestampValidBits;
    VkExtent3D minImageTransferGranularity;
} VkQueueFamilyProperties;
```

- **queueFlags** is a bitmask of **VkQueueFlagBits** indicating capabilities of the queues in this queue family.
- **queueCount** is the unsigned integer count of queues in this queue family. Each queue family **must** support at least one queue.
- **timestampValidBits** is the unsigned integer count of meaningful bits in the timestamps written via **vkCmdWriteTimestamp**. The valid range for the count is 36..64 bits, or a value of **0**, indicating no support for timestamps. Bits outside the valid range are guaranteed to be zeros.
- **minImageTransferGranularity** is the minimum granularity supported for image transfer.
operations on the queues in this queue family.

The value returned in `minImageTransferGranularity` has a unit of compressed texel blocks for images having a block-compressed format, and a unit of texels otherwise.

Possible values of `minImageTransferGranularity` are:

- (0,0,0) which indicates that only whole mip levels must be transferred using the image transfer operations on the corresponding queues. In this case, the following restrictions apply to all offset and extent parameters of image transfer operations:
  - The `x`, `y`, and `z` members of a `VkOffset3D` parameter must always be zero.
  - The `width`, `height`, and `depth` members of a `VkExtent3D` parameter must always match the width, height, and depth of the image subresource corresponding to the parameter, respectively.

- `(A_x, A_y, A_z)` where `A_x`, `A_y`, and `A_z` are all integer powers of two. In this case the following restrictions apply to all image transfer operations:
  - `x`, `y`, and `z` of a `VkOffset3D` parameter must be integer multiples of `A_x`, `A_y`, and `A_z`, respectively.
  - `width` of a `VkExtent3D` parameter must be an integer multiple of `A_x`, or else `x + width` must equal the width of the image subresource corresponding to the parameter.
  - `height` of a `VkExtent3D` parameter must be an integer multiple of `A_y`, or else `y + height` must equal the height of the image subresource corresponding to the parameter.
  - `depth` of a `VkExtent3D` parameter must be an integer multiple of `A_z`, or else `z + depth` must equal the depth of the image subresource corresponding to the parameter.
  - If the format of the image corresponding to the parameters is one of the block-compressed formats then for the purposes of the above calculations the granularity must be scaled up by the compressed texel block dimensions.

Queues supporting graphics and/or compute operations must report (1,1,1) in `minImageTransferGranularity`, meaning that there are no additional restrictions on the granularity of image transfer operations for these queues. Other queues supporting image transfer operations are only required to support whole mip level transfers, thus `minImageTransferGranularity` for queues belonging to such queue families may be (0,0,0).

The Device Memory section describes memory properties queried from the physical device.

For physical device feature queries see the Features chapter.

Bits which may be set in `VkQueueFamilyProperties::queueFlags` indicating capabilities of queues in a queue family are:
typedef enum VkQueueFlagBits {
    VK_QUEUE_GRAPHICS_BIT = 0x00000001,
    VK_QUEUE_COMPUTE_BIT = 0x00000002,
    VK_QUEUE_TRANSFER_BIT = 0x00000004,
    VK_QUEUE_SPARSE_BINDING_BIT = 0x00000008,
} VkQueueFlagBits;

- **VK_QUEUE_GRAPHICS_BIT** specifies that queues in this queue family support graphics operations.
- **VK_QUEUE_COMPUTE_BIT** specifies that queues in this queue family support compute operations.
- **VK_QUEUE_TRANSFER_BIT** specifies that queues in this queue family support transfer operations.
- **VK_QUEUE_SPARSE_BINDING_BIT** specifies that queues in this queue family support sparse memory management operations (see Sparse Resources). If any of the sparse resource features are enabled, then at least one queue family must support this bit.

If an implementation exposes any queue family that supports graphics operations, at least one queue family of at least one physical device exposed by the implementation must support both graphics and compute operations.

Note

All commands that are allowed on a queue that supports transfer operations are also allowed on a queue that supports either graphics or compute operations. Thus, if the capabilities of a queue family include **VK_QUEUE_GRAPHICS_BIT** or **VK_QUEUE_COMPUTE_BIT**, then reporting the **VK_QUEUE_TRANSFER_BIT** capability separately for that queue family is optional.

For further details see Queues.

typedef VkFlags VkQueueFlags;

VkQueueFlags is a bitmask type for setting a mask of zero or more VkQueueFlagBits.

To query properties of queues available on a physical device, call:

```c
void vkGetPhysicalDeviceQueueFamilyProperties2KHR(
    VkPhysicalDevice                               physicalDevice,
    uint32_t*                                       pQueueFamilyPropertyCount,
    VkQueueFamilyProperties2*                     pQueueFamilyProperties);
```

- **physicalDevice** is the handle to the physical device whose properties will be queried.
- **pQueueFamilyPropertyCount** is a pointer to an integer related to the number of queue families available or queried, as described in vkGetPhysicalDeviceQueueFamilyProperties.
- **pQueueFamilyProperties** is either NULL or a pointer to an array of VkQueueFamilyProperties2 structures.
vkGetPhysicalDeviceQueueFamilyProperties2 behaves similarly to vkGetPhysicalDeviceQueueFamilyProperties, with the ability to return extended information in a pNext chain of output structures.

**Valid Usage (Implicit)**

- **physicalDevice** must be a valid VkPhysicalDevice handle
- **pQueueFamilyPropertyCount** must be a valid pointer to a uint32_t value
- If the value referenced by pQueueFamilyPropertyCount is not 0, and pQueueFamilyProperties is not NULL, pQueueFamilyProperties must be a valid pointer to an array of pQueueFamilyPropertyCount VkQueueFamilyProperties2 structures

The VkQueueFamilyProperties2 structure is defined as:

```c
typedef struct VkQueueFamilyProperties2 {
    VkStructureType sType;
    void* pNext;
    VkQueueFamilyProperties queueFamilyProperties;
} VkQueueFamilyProperties2;
```

or the equivalent

```c
typedef VkQueueFamilyProperties2 VkQueueFamilyProperties2KHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **queueFamilyProperties** is a VkQueueFamilyProperties structure which is populated with the same values as in vkGetPhysicalDeviceQueueFamilyProperties.

**Valid Usage (Implicit)**

- **sType** must be VK_STRUCTURE_TYPE_QUEUE_FAMILY_PROPERTIES_2
- **pNext** must be NULL or a pointer to a valid instance of VkQueueFamilyCheckpointPropertiesNV
- The **sType** value of each struct in the **pNext** chain must be unique

Additional queue family information can be queried by setting VkQueueFamilyProperties2::pNext to point to a VkQueueFamilyCheckpointPropertiesNV structure.

The VkQueueFamilyCheckpointPropertiesNV structure is defined as:
typedef struct VkQueueFamilyCheckpointPropertiesNV {
    VkStructureType               sType;
    void*                         pNext;
    VkPipelineStageFlags          checkpointExecutionStageMask;
} VkQueueFamilyCheckpointPropertiesNV;

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **checkpointExecutionStageMask** is a mask indicating which pipeline stages the implementation can execute checkpoint markers in.

### Valid Usage (Implicit)

- **sType** **must** be `VK_STRUCTURE_TYPE_QUEUE_FAMILY_CHECKPOINT_PROPERTIES_NV`

To enumerate the performance query counters available on a queue family of a physical device, call:

```c
VkResult vkEnumeratePhysicalDeviceQueueFamilyPerformanceQueryCountersKHR(
    VkPhysicalDevice                            physicalDevice,
    uint32_t                                    queueFamilyIndex,
    uint32_t*                                   pCounterCount,
    VkPerformanceCounterKHR*                    pCounters,
    VkPerformanceCounterDescriptionKHR*         pCounterDescriptions);
```

- **physicalDevice** is the handle to the physical device whose queue family performance query counter properties will be queried.
- **queueFamilyIndex** is the index into the queue family of the physical device we want to get properties for.
- **pCounterCount** is a pointer to an integer related to the number of counters available or queried, as described below.
- **pCounters** is either **NULL** or a pointer to an array of `VkPerformanceCounterKHR` structures.
- **pCounterDescriptions** is either **NULL** or a pointer to an array of `VkPerformanceCounterDescriptionKHR` structures.

If **pCounters** is **NULL** and **pCounterDescriptions** is **NULL**, then the number of counters available is returned in **pCounterCount**. Otherwise, **pCounterCount** **must** point to a variable set by the user to the number of elements in the **pCounters**, **pCounterDescriptions**, or both arrays and on return the variable is overwritten with the number of structures actually written out. If **pCounterCount** is less than the number of counters available, at most **pCounterCount** structures will be written and **VK_INCOMPLETE** will be returned instead of **VK_SUCCESS**.
Valid Usage (Implicit)

- **physicalDevice** must be a valid `VkPhysicalDevice` handle
- **pCounterCount** must be a valid pointer to a `uint32_t` value
- If the value referenced by `pCounterCount` is not 0, and `pCounters` is not NULL, `pCounters` must be a valid pointer to an array of `VkPerformanceCounterKHR` structures
- If the value referenced by `pCounterCount` is not 0, and `pCounterDescriptions` is not NULL, `pCounterDescriptions` must be a valid pointer to an array of `VkPerformanceCounterDescriptionKHR` structures

Return Codes

**Success**
- `VK_SUCCESS`
- `VK_INCOMPLETE`

**Failure**
- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`
- `VK_ERROR_INITIALIZATION_FAILED`

The `VkPerformanceCounterKHR` structure is defined as:

```c
typedef struct VkPerformanceCounterKHR {
    VkStructureType sType;
    const void* pNext;
    VkPerformanceCounterUnitKHR unit;
    VkPerformanceCounterScopeKHR scope;
    VkPerformanceCounterStorageKHR storage;
    uint8_t uuid[VK_UUID_SIZE];
} VkPerformanceCounterKHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **unit** is a `VkPerformanceCounterUnitKHR` specifying the unit that the counter data will record.
- **scope** is a `VkPerformanceCounterScopeKHR` specifying the scope that the counter belongs to.
- **storage** is a `VkPerformanceCounterStorageKHR` specifying the storage type that the counter’s data uses.
- **uuid** is an array of size `VK_UUID_SIZE`, containing 8-bit values that represent a universally unique identifier for the counter of the physical device.
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_PERFORMANCE_COUNTER_KHR`
- **pNext** must be `NULL`

Performance counters have an associated unit. This unit describes how to interpret the performance counter result.

The performance counter unit types which **may** be returned in `VkPerformanceCounterKHR::unit` are:

```cpp
typedef enum VkPerformanceCounterUnitKHR {
    VK_PERFORMANCE_COUNTER_UNIT_GENERIC_KHR = 0,
    VK_PERFORMANCE_COUNTER_UNIT_PERCENTAGE_KHR = 1,
    VK_PERFORMANCE_COUNTER_UNIT_NANOSECONDS_KHR = 2,
    VK_PERFORMANCE_COUNTER_UNIT_BYTES_KHR = 3,
    VK_PERFORMANCE_COUNTER_UNIT_BYTES_PER_SECOND_KHR = 4,
    VK_PERFORMANCE_COUNTER_UNIT_KELVIN_KHR = 5,
    VK_PERFORMANCE_COUNTER_UNIT_WATTS_KHR = 6,
    VK_PERFORMANCE_COUNTER_UNIT_VOLTS_KHR = 7,
    VK_PERFORMANCE_COUNTER_UNIT_AMPS_KHR = 8,
    VK_PERFORMANCE_COUNTER_UNIT_HERTZ_KHR = 9,
    VK_PERFORMANCE_COUNTER_UNIT_CYCLES_KHR = 10,
} VkPerformanceCounterUnitKHR;
```

- **VK_PERFORMANCE_COUNTER_UNIT_GENERIC_KHR** - the performance counter unit is a generic data point.
- **VK_PERFORMANCE_COUNTER_UNIT_PERCENTAGE_KHR** - the performance counter unit is a percentage (%).
- **VK_PERFORMANCE_COUNTER_UNIT_NANOSECONDS_KHR** - the performance counter unit is a value of nanoseconds (ns).
- **VK_PERFORMANCE_COUNTER_UNIT_BYTES_KHR** - the performance counter unit is a value of bytes.
- **VK_PERFORMANCE_COUNTER_UNIT_BYTES_PER_SECOND_KHR** - the performance counter unit is a value of bytes/s.
- **VK_PERFORMANCE_COUNTER_UNIT_KELVIN_KHR** - the performance counter unit is a temperature reported in Kelvin.
- **VK_PERFORMANCE_COUNTER_UNIT_WATTS_KHR** - the performance counter unit is a value of watts (W).
- **VK_PERFORMANCE_COUNTER_UNIT_VOLTS_KHR** - the performance counter unit is a value of volts (V).
- **VK_PERFORMANCE_COUNTER_UNIT_AMPS_KHR** - the performance counter unit is a value of amps (A).
- **VK_PERFORMANCE_COUNTER_UNIT_HERTZ_KHR** - the performance counter unit is a value of hertz (Hz).
- **VK_PERFORMANCE_COUNTER_UNIT_CYCLES_KHR** - the performance counter unit is a value of cycles.

Performance counters have an associated scope. This scope describes the granularity of a performance counter.
The performance counter scope types which **may** be returned in `VkPerformanceCounterKHR::scope` are:

```c
typedef enum VkPerformanceCounterScopeKHR {
    VK_PERFORMANCE_COUNTER_SCOPE_COMMAND_BUFFER_KHR = 0,
    VK_PERFORMANCE_COUNTER_SCOPE_RENDER_PASS_KHR = 1,
    VK_PERFORMANCE_COUNTER_SCOPE_COMMAND_KHR = 2,
    VK_QUERY_SCOPE_COMMAND_BUFFER_KHR =
    VK_PERFORMANCE_COUNTER_SCOPE_COMMAND_BUFFER_KHR,
    VK_QUERY_SCOPE_RENDER_PASS_KHR = VK_PERFORMANCE_COUNTER_SCOPE_RENDER_PASS_KHR,
    VK_QUERY_SCOPE_COMMAND_KHR = VK_PERFORMANCE_COUNTER_SCOPE_COMMAND_KHR,
} VkPerformanceCounterScopeKHR;
```

- **VK_PERFORMANCE_COUNTER_SCOPE_COMMAND_BUFFER_KHR** - the performance counter scope is a single complete command buffer.
- **VK_PERFORMANCE_COUNTER_SCOPE_RENDER_PASS_KHR** - the performance counter scope is zero or more complete render passes. The performance query containing the performance counter **must** begin and end outside a render pass instance.
- **VK_PERFORMANCE_COUNTER_SCOPE_COMMAND_KHR** - the performance counter scope is zero or more commands.

Performance counters have an associated storage. This storage describes the payload of a counter result.

The performance counter storage types which **may** be returned in `VkPerformanceCounterKHR::storage` are:

```c
typedef enum VkPerformanceCounterStorageKHR {
    VK_PERFORMANCE_COUNTER_STORAGE_INT32_KHR = 0,
    VK_PERFORMANCE_COUNTER_STORAGE_INT64_KHR = 1,
    VK_PERFORMANCE_COUNTER_STORAGE_UINT32_KHR = 2,
    VK_PERFORMANCE_COUNTER_STORAGE_UINT64_KHR = 3,
    VK_PERFORMANCE_COUNTER_STORAGE_FLOAT32_KHR = 4,
    VK_PERFORMANCE_COUNTER_STORAGE_FLOAT64_KHR = 5,
} VkPerformanceCounterStorageKHR;
```

- **VK_PERFORMANCE_COUNTER_STORAGE_INT32_KHR** - the performance counter storage is a 32-bit signed integer.
- **VK_PERFORMANCE_COUNTER_STORAGE_INT64_KHR** - the performance counter storage is a 64-bit signed integer.
- **VK_PERFORMANCE_COUNTER_STORAGE_UINT32_KHR** - the performance counter storage is a 32-bit unsigned integer.
- **VK_PERFORMANCE_COUNTER_STORAGE_UINT64_KHR** - the performance counter storage is a 64-bit unsigned integer.
- **VK_PERFORMANCE_COUNTER_STORAGE_FLOAT32_KHR** - the performance counter storage is a 32-bit floating-point number.
- **VK_PERFORMANCE_COUNTER_STORAGE_FLOAT64_KHR** - the performance counter storage is a 64-bit floating-point number.
floating-point.

- **VK_PERFORMANCE_COUNTER_STORAGE_FLOAT64_KHR** - the performance counter storage is a 64-bit floating-point.

The `VkPerformanceCounterDescriptionKHR` structure is defined as:

```c
typedef struct VkPerformanceCounterDescriptionKHR {
    VkStructureType sType;
    const void* pNext;
    VkPerformanceCounterDescriptionFlagsKHR flags;
    char name[VK_MAX_DESCRIPTION_SIZE];
    char category[VK_MAX_DESCRIPTION_SIZE];
    char description[VK_MAX_DESCRIPTION_SIZE];
} VkPerformanceCounterDescriptionKHR;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkPerformanceCounterDescriptionFlagBitsKHR` indicating the usage behavior for the counter.
- **name** is an array of size `VK_MAX_DESCRIPTION_SIZE`, containing a null-terminated UTF-8 string specifying the name of the counter.
- **category** is an array of size `VK_MAX_DESCRIPTION_SIZE`, containing a null-terminated UTF-8 string specifying the category of the counter.
- **description** is an array of size `VK_MAX_DESCRIPTION_SIZE`, containing a null-terminated UTF-8 string specifying the description of the counter.

### Valid Usage (Implicit)

- **sType** **must** be `VK_STRUCTURE_TYPE_PERFORMANCE_COUNTER_DESCRIPTION_KHR`
- **pNext** **must** be `NULL`

Bits which **can** be set in `VkPerformanceCounterDescriptionKHR::flags` to specify usage behavior for a command pool are:

```c
typedef enum VkPerformanceCounterDescriptionFlagBitsKHR {
    VK_PERFORMANCE_COUNTER_DESCRIPTION_PERFORMANCE_IMPACTING_KHR = 0x00000001,
    VK_PERFORMANCE_COUNTER_DESCRIPTION_CONCURRENTLY_IMPACTED_KHR = 0x00000002,
} VkPerformanceCounterDescriptionFlagBitsKHR;
```

- **VK_PERFORMANCE_COUNTER_DESCRIPTION_PERFORMANCE_IMPACTING_KHR** specifies that recording the counter **may** have a noticeable performance impact.
- **VK_PERFORMANCE_COUNTER_DESCRIPTION_CONCURRENTLY_IMPACTED_KHR** specifies that concurrently recording the counter while other submitted command buffers are running **may** impact the
accuracy of the recording.

```c
typedef VkFlags VkPerformanceCounterDescriptionFlagsKHR;
```

 VkPerformanceCounterDescriptionFlagsKHR is a bitmask type for setting a mask of zero or moreVkPerformanceCounterDescriptionFlagBitsKHR.

## 4.2. Devices

Device objects represent logical connections to physical devices. Each device exposes a number of queue families each having one or more queues. All queues in a queue family support the same operations.

As described in **Physical Devices**, a Vulkan application will first query for all physical devices in a system. Each physical device can then be queried for its capabilities, including its queue and queue family properties. Once an acceptable physical device is identified, an application will create a corresponding logical device. An application must create a separate logical device for each physical device it will use. The created logical device is then the primary interface to the physical device.

How to enumerate the physical devices in a system and query those physical devices for their queue family properties is described in the **Physical Device Enumeration** section above.

A single logical device can also be created from multiple physical devices, if those physical devices belong to the same device group. A device group is a set of physical devices that support accessing each other’s memory and recording a single command buffer that can be executed on all the physical devices. Device groups are enumerated by calling `vkEnumeratePhysicalDeviceGroups`, and a logical device is created from a subset of the physical devices in a device group by passing the physical devices through `VkDeviceGroupDeviceCreateInfo`. For two physical devices to be in the same device group, they must support identical extensions, features, and properties.

```
Note
Physical devices in the same device group must be so similar because there are no rules for how different features/properties would interact. They must return the same values for nearly every invariant `vkGetPhysicalDevice*` feature, property, capability, etc., but could potentially differ for certain queries based on things like having a different display connected, or different compositor, etc.. The specification does not attempt to enumerate which state is in each category, because such a list would quickly become out of date.
```

To retrieve a list of the device groups present in the system, call:

```c
VkResult vkEnumeratePhysicalDeviceGroupsKHR(
    VkInstance instance,
    uint32_t* pPhysicalDeviceGroupCount,
    VkPhysicalDeviceGroupProperties* pPhysicalDeviceGroupProperties);
```
• `instance` is a handle to a Vulkan instance previously created with `vkCreateInstance`.

• `pPhysicalDeviceGroupCount` is a pointer to an integer related to the number of device groups available or queried, as described below.

• `pPhysicalDeviceGroupProperties` is either `NULL` or a pointer to an array of `VkPhysicalDeviceGroupProperties` structures.

If `pPhysicalDeviceGroupProperties` is `NULL`, then the number of device groups available is returned in `pPhysicalDeviceGroupCount`. Otherwise, `pPhysicalDeviceGroupCount` must point to a variable set by the user to the number of elements in the `pPhysicalDeviceGroupProperties` array, and on return the variable is overwritten with the number of structures actually written to `pPhysicalDeviceGroupProperties`. If `pPhysicalDeviceGroupCount` is less than the number of device groups available, at most `pPhysicalDeviceGroupCount` structures will be written. If `pPhysicalDeviceGroupCount` is smaller than the number of device groups available, `VK_INCOMPLETE` will be returned instead of `VK_SUCCESS`, to indicate that not all the available device groups were returned.

Every physical device must be in exactly one device group.

---

### Valid Usage (Implicit)

- `instance` must be a valid `VkInstance` handle

- `pPhysicalDeviceGroupCount` must be a valid pointer to a `uint32_t` value

- If the value referenced by `pPhysicalDeviceGroupCount` is not 0, and `pPhysicalDeviceGroupProperties` is not `NULL`, `pPhysicalDeviceGroupProperties` must be a valid pointer to an array of `pPhysicalDeviceGroupCount` `VkPhysicalDeviceGroupProperties` structures

### Return Codes

#### Success

- `VK_SUCCESS`

- `VK_INCOMPLETE`

#### Failure

- `VK_ERROR_OUT_OF_HOST_MEMORY`

- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

- `VK_ERROR_INITIALIZATION_FAILED`

The `VkPhysicalDeviceGroupProperties` structure is defined as:

```c
typedef struct VkPhysicalDeviceGroupProperties {
    VkStructureType     sType;
    void*               pNext;
    uint32_t            physicalDeviceCount;
    VkPhysicalDevice    physicalDevices[VK_MAX_DEVICE_GROUP_SIZE];
    VkBool32            subsetAllocation;
} VkPhysicalDeviceGroupProperties;
```

or the equivalent

```c
typedef VkPhysicalDeviceGroupProperties VkPhysicalDeviceGroupPropertiesKHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **physicalDeviceCount** is the number of physical devices in the group.
- **physicalDevices** is an array of `VK_MAX_DEVICE_GROUP_SIZE` `VkPhysicalDevice` handles representing all physical devices in the group. The first `physicalDeviceCount` elements of the array will be valid.
- **subsetAllocation** specifies whether logical devices created from the group support allocating device memory on a subset of devices, via the `deviceMask` member of the `VkMemoryAllocateFlagsInfo`. If this is `VK_FALSE`, then all device memory allocations are made across all physical devices in the group. If `physicalDeviceCount` is 1, then `subsetAllocation` must be `VK_FALSE`.

**Valid Usage (Implicit)**

- **sType** must be `VK_STRUCTURE_TYPE_PHYSICAL_DEVICE_GROUP_PROPERTIES`
- **pNext** must be NULL

### 4.2.1. Device Creation

Logical devices are represented by `VkDevice` handles:

```c
VK_DEFINE_HANDLE(VkDevice)
```

A logical device is created as a `connection` to a physical device. To create a logical device, call:
VkResult vkCreateDevice(
    VkPhysicalDevice                            physicalDevice,
    const VkDeviceCreateInfo*                   pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkDevice*                                   pDevice);

• physicalDevice must be one of the device handles returned from a call to vkEnumeratePhysicalDevices (see Physical Device Enumeration).

• pCreateInfo is a pointer to a VkDeviceCreateInfo structure containing information about how to create the device.

• pAllocator controls host memory allocation as described in the Memory Allocation chapter.

• pDevice is a pointer to a handle in which the created VkDevice is returned.

vkCreateDevice verifies that extensions and features requested in the ppEnabledExtensionNames and pEnabledFeatures members of pCreateInfo, respectively, are supported by the implementation. If any requested extension is not supported, vkCreateDevice must return VK_ERROR_EXTENSION_NOT_PRESENT. If any requested feature is not supported, vkCreateDevice must return VK_ERROR_FEATURE_NOT_PRESENT. Support for extensions can be checked before creating a device by querying vkEnumerateDeviceExtensionProperties. Support for features can similarly be checked by querying vkGetPhysicalDeviceFeatures.

After verifying and enabling the extensions the VkDevice object is created and returned to the application. If a requested extension is only supported by a layer, both the layer and the extension need to be specified at vkCreateInstance time for the creation to succeed.

Multiple logical devices can be created from the same physical device. Logical device creation may fail due to lack of device-specific resources (in addition to the other errors). If that occurs, vkCreateDevice will return VK_ERROR_TOO_MANY_OBJECTS.

Valid Usage

• All required extensions for each extension in the VkDeviceCreateInfo ::ppEnabledExtensionNames list must also be present in that list

Valid Usage (Implicit)

• physicalDevice must be a valid VkPhysicalDevice handle

• pCreateInfo must be a valid pointer to a valid VkDeviceCreateInfo structure

• If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure

• pDevice must be a valid pointer to a VkDevice handle
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY
• VK_ERROR_INITIALIZATION_FAILED
• VK_ERROR_EXTENSION_NOT_PRESENT
• VK_ERROR_FEATURE_NOT_PRESENT
• VK_ERROR_TOO_MANY_OBJECTS
• VK_ERROR_DEVICE_LOST

The VkDeviceCreateInfo structure is defined as:

```c
typedef struct VkDeviceCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkDeviceCreateFlags flags;
    uint32_t queueCreateInfoCount;
    const VkDeviceQueueCreateInfo* pQueueCreateInfos;
    uint32_t enabledLayerCount;
    const char** ppEnabledLayerNames;
    uint32_t enabledExtensionCount;
    const char** ppEnabledExtensionNames;
    const VkPhysicalDeviceFeatures* pEnabledFeatures;
} VkDeviceCreateInfo;
```

• `sType` is the type of this structure.
• `pNext` is NULL or a pointer to an extension-specific structure.
• `flags` is reserved for future use.
• `queueCreateInfoCount` is the unsigned integer size of the `pQueueCreateInfos` array. Refer to the Queue Creation section below for further details.
• `pQueueCreateInfos` is a pointer to an array of VkDeviceQueueCreateInfo structures describing the queues that are requested to be created along with the logical device. Refer to the Queue Creation section below for further details.
• `enabledLayerCount` is deprecated and ignored.
• `ppEnabledLayerNames` is deprecated and ignored. See Device Layer Deprecation.
• `enabledExtensionCount` is the number of device extensions to enable.
• `ppEnabledExtensionNames` is a pointer to an array of `enabledExtensionCount` null-terminated UTF-8
strings containing the names of extensions to enable for the created device. See the Extensions section for further details.

- `pEnabledFeatures` is `NULL` or a pointer to a `VkPhysicalDeviceFeatures` structure containing boolean indicators of all the features to be enabled. Refer to the Features section for further details.

**Valid Usage**

- The `queueFamilyIndex` member of each element of `pQueueCreateInfos` must be unique within `pQueueCreateInfos`
- If the `pNext` chain includes a `VkPhysicalDeviceFeatures2` structure, then `pEnabledFeatures` must be `NULL`
- `ppEnabledExtensionNames` must not contain both `VK_KHR_maintenance1` and `VK_AMD_negative_viewport_height`
- `ppEnabledExtensionNames` must not contain both `VK_KHR_buffer_device_address` and `VK_EXT_buffer_device_address`
Valid Usage (Implicit)

- **sType** must be **VK_STRUCTURE_TYPE_DEVICE_CREATE_INFO**

• The sType value of each struct in the pNext chain must be unique
• flags must be 0
• pQueueCreateInfos must be a valid pointer to an array of queueCreateInfoCount valid VkDeviceQueueCreateInfo structures
  • If enabledLayerCount is not 0, ppEnabledLayerNames must be a valid pointer to an array of enabledLayerCount null-terminated UTF-8 strings
  • If enabledExtensionCount is not 0, ppEnabledExtensionNames must be a valid pointer to an array of enabledExtensionCount null-terminated UTF-8 strings
  • If pEnabledFeatures is not NULL, pEnabledFeatures must be a valid pointer to a valid VkPhysicalDeviceFeatures structure
• queueCreateInfoCount must be greater than 0

typedef VkFlags VkDeviceCreateFlags;

VkDeviceCreateFlags is a bitmask type for setting a mask, but is currently reserved for future use.

A logical device can be created that connects to one or more physical devices by adding a VkDeviceGroupDeviceCreateInfo structure to the pNext chain of VkDeviceCreateInfo. The VkDeviceGroupDeviceCreateInfo structure is defined as:

```c
typedef struct VkDeviceGroupDeviceCreateInfo {
    VkStructureType sType;
    const void* pNext;
    uint32_t physicalDeviceCount;
    const VkPhysicalDevice* pPhysicalDevices;
} VkDeviceGroupDeviceCreateInfo;
```

or the equivalent
typedef VkDeviceGroupDeviceCreateInfo VkDeviceGroupDeviceCreateInfoKHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **physicalDeviceCount** is the number of elements in the pPhysicalDevices array.
- **pPhysicalDevices** is a pointer to an array of physical device handles belonging to the same device group.

The elements of the pPhysicalDevices array are an ordered list of the physical devices that the logical device represents. These **must** be a subset of a single device group, and need not be in the same order as they were enumerated. The order of the physical devices in the pPhysicalDevices array determines the **device index** of each physical device, with element i being assigned a device index of i. Certain commands and structures refer to one or more physical devices by using device indices or **device masks** formed using device indices.

A logical device created without using VkDeviceGroupDeviceCreateInfo, or with physicalDeviceCount equal to zero, is equivalent to a physicalDeviceCount of one and pPhysicalDevices pointing to the physicalDevice parameter to vkCreateDevice. In particular, the device index of that physical device is zero.

### Valid Usage

- Each element of pPhysicalDevices **must** be unique
- All elements of pPhysicalDevices **must** be in the same device group as enumerated by vkEnumeratePhysicalDeviceGroups
- If physicalDeviceCount is not 0, the physicalDevice parameter of vkCreateDevice **must** be an element of pPhysicalDevices

### Valid Usage (Implicit)

- **sType** **must** be VK_STRUCTURE_TYPE_DEVICE_GROUP_DEVICE_CREATE_INFO
- If physicalDeviceCount is not 0, pPhysicalDevices **must** be a valid pointer to an array of physicalDeviceCount valid VkPhysicalDevice handles

To specify whether device memory allocation is allowed beyond the size reported by VkPhysicalDeviceMemoryProperties, add a VkDeviceMemoryOverallocationCreateInfoAMD structure to the pNext chain of the VkDeviceCreateInfo structure. If this structure is not specified, it is as if the VK_MEMORY_OVERALLOCATION_BEHAVIOR_DEFAULT_AMD value is used.
typedef struct VkDeviceMemoryOverallocationCreateInfoAMD {
    VkStructureType                      sType;
    const void*                          pNext;
    VkMemoryOverallocationBehaviorAMD    overallocationBehavior;
} VkDeviceMemoryOverallocationCreateInfoAMD;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `overallocationBehavior` is the desired overallocation behavior.

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_DEVICE_MEMORY_OVERALLOCATION_CREATE_INFO_AMD`
- `overallocationBehavior` must be a valid `VkMemoryOverallocationBehaviorAMD` value

Possible values for `VkDeviceMemoryOverallocationCreateInfoAMD::overallocationBehavior` include:

```c
typedef enum VkMemoryOverallocationBehaviorAMD {
    VK_MEMORY_OVERALLOCATION_BEHAVIOR_DEFAULT_AMD = 0,
    VK_MEMORY_OVERALLOCATION_BEHAVIOR_ALLOWED_AMD = 1,
    VK_MEMORY_OVERALLOCATION_BEHAVIOR_DISALLOWED_AMD = 2,
} VkMemoryOverallocationBehaviorAMD;
```

- `VK_MEMORY_OVERALLOCATION_BEHAVIOR_DEFAULT_AMD` lets the implementation decide if overallocation is allowed.
- `VK_MEMORY_OVERALLOCATION_BEHAVIOR_ALLOWED_AMD` specifies overallocation is allowed if platform permits.
- `VK_MEMORY_OVERALLOCATION_BEHAVIOR_DISALLOWED_AMD` specifies the application is not allowed to allocate device memory beyond the heap sizes reported by `VkPhysicalDeviceMemoryProperties`. Allocations that are not explicitly made by the application within the scope of the Vulkan instance are not accounted for.

When using the Nsight™ Aftermath SDK, to configure how device crash dumps are created, add a `VkDeviceDiagnosticsConfigCreateInfoNV` structure to the `pNext` chain of the `VkDeviceCreateInfo` structure.

```c
typedef struct VkDeviceDiagnosticsConfigCreateInfoNV {
    VkStructureType                     sType;
    const void*                         pNext;
    VkDeviceDiagnosticsConfigFlagsNV    flags;
} VkDeviceDiagnosticsConfigCreateInfoNV;
```
• **sType** is the type of this structure.

• **pNext** is NULL or a pointer to an extension-specific structure.

• **flags** is a bitmask of `VkDeviceDiagnosticsConfigFlagBitsNV` specifying additional parameters for configuring diagnostic tools.

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_DEVICE_DIAGNOSTICS_CONFIG_CREATE_INFO_NV`.
- **flags** must be a valid combination of `VkDeviceDiagnosticsConfigFlagBitsNV` values.

Bits which **can** be set in `VkDeviceDiagnosticsConfigCreateInfoNV::flags` include:

```c
typedef enum VkDeviceDiagnosticsConfigFlagBitsNV {
    VK_DEVICE_DIAGNOSTICS_CONFIG_ENABLE_SHADER_DEBUG_INFO_BIT_NV = 0x00000001,
    VK_DEVICE_DIAGNOSTICS_CONFIG_ENABLE_RESOURCE_TRACKING_BIT_NV = 0x00000002,
    VK_DEVICE_DIAGNOSTICS_CONFIG_ENABLE_AUTOMATIC_CHECKPOINTS_BIT_NV = 0x00000004,
} VkDeviceDiagnosticsConfigFlagBitsNV;
```

- **VK_DEVICE_DIAGNOSTICS_CONFIG_ENABLE_SHADER_DEBUG_INFO_BIT_NV** enables the generation of debug information for shaders.
- **VK_DEVICE_DIAGNOSTICS_CONFIG_ENABLE_RESOURCE_TRACKING_BIT_NV** enables driver side tracking of resources (images, buffers, etc.) used to augment the device fault information.
- **VK_DEVICE_DIAGNOSTICS_CONFIG_ENABLE_AUTOMATIC_CHECKPOINTS_BIT_NV** enables automatic insertion of diagnostic checkpoints for draw calls, dispatches, trace rays, and copies. The CPU call stack at the time of the command will be associated as the marker data for the automatically inserted checkpoints.

```c
typedef VkFlags VkDeviceDiagnosticsConfigFlagsNV;
```

`VkDeviceDiagnosticsConfigFlagsNV` is a bitmask type for setting a mask of zero or more `VkDeviceDiagnosticsConfigFlagBitsNV`.

To reserve private data storage slots, add a `VkDevicePrivateDataCreateInfoEXT` structure to the **pNext** chain of the `VkDeviceCreateInfo` structure. Reserving slots in this manner is not strictly necessary, but doing so **may** improve performance.

```c
typedef struct VkDevicePrivateDataCreateInfoEXT {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           privateDataSlotRequestCount;
} VkDevicePrivateDataCreateInfoEXT;
```

• **sType** is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• privateDataSlotRequestCount is the amount of slots to reserve.

<table>
<thead>
<tr>
<th>Valid Usage (Implicit)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sType must be VK_STRUCTURE_TYPE_DEVICE_PRIVATE_DATA_CREATE_INFO_EXT</td>
</tr>
<tr>
<td>pNext must be NULL</td>
</tr>
</tbody>
</table>

4.2.2. Device Use

The following is a high-level list of VkDevice uses along with references on where to find more information:

• Creation of queues. See the Queues section below for further details.
• Creation and tracking of various synchronization constructs. See Synchronization and Cache Control for further details.
• Allocating, freeing, and managing memory. See Memory Allocation and Resource Creation for further details.
• Creation and destruction of command buffers and command buffer pools. See Command Buffers for further details.
• Creation, destruction, and management of graphics state. See Pipelines and Resource Descriptors, among others, for further details.

4.2.3. Lost Device

A logical device may become lost for a number of implementation-specific reasons, indicating that pending and future command execution may fail and cause resources and backing memory to become undefined.

Note
Typical reasons for device loss will include things like execution timing out (to prevent denial of service), power management events, platform resource management, implementation errors.

Applications not adhering to valid usage may also result in device loss being reported, however this is not guaranteed. Even if device loss is reported, the system may be in an unrecoverable state, and further usage of the API is still considered invalid.

When this happens, certain commands will return VK_ERROR_DEVICE_LOST. After any such event, the logical device is considered lost. It is not possible to reset the logical device to a non-lost state, however the lost state is specific to a logical device (VkDevice), and the corresponding physical device (VkPhysicalDevice) may be otherwise unaffected.

In some cases, the physical device may also be lost, and attempting to create a new logical device
will fail, returning \texttt{VK\_ERROR\_DEVICE\_LOST}. This is usually indicative of a problem with the underlying implementation, or its connection to the host. If the physical device has not been lost, and a new logical device is successfully created from that physical device, it \textbf{must} be in the non-lost state.

\textbf{Note}

Whilst logical device loss \textit{may} be recoverable, in the case of physical device loss, it is unlikely that an application will be able to recover unless additional, unaffected physical devices exist on the system. The error is largely informational and intended only to inform the user that a platform issue has occurred, and \textbf{should} be investigated further. For example, underlying hardware \textit{may} have developed a fault or become physically disconnected from the rest of the system. In many cases, physical device loss \textit{may} cause other more serious issues such as the operating system crashing; in which case it \textit{may} not be reported via the Vulkan API.

When a device is lost, its child objects are not implicitly destroyed and their handles are still valid. Those objects \textbf{must} still be destroyed before their parents or the device \textbf{can} be destroyed (see the \texttt{Object Lifetime} section). The host address space corresponding to device memory mapped using \texttt{vkMapMemory} is still valid, and host memory accesses to these mapped regions are still valid, but the contents are undefined. It is still legal to call any API command on the device and child objects.

Once a device is lost, command execution \textit{may} fail, and commands that return a \texttt{VkResult} \textit{may} return \texttt{VK\_ERROR\_DEVICE\_LOST}. Commands that do not allow runtime errors \textbf{must} still operate correctly for valid usage and, if applicable, return valid data.

Commands that wait indefinitely for device execution (namely \texttt{vkDeviceWaitIdle}, \texttt{vkQueueWaitIdle}, \texttt{vkWaitForFences} or \texttt{vkAcquireNextImageKHR} with a maximum \texttt{timeout}, and \texttt{vkGetQueryPoolResults} with the \texttt{VK\_QUERY\_RESULT\_WAIT\_BIT} bit set in flags) \textbf{must} return in finite time even in the case of a lost device, and return either \texttt{VK\_SUCCESS} or \texttt{VK\_ERROR\_DEVICE\_LOST}. For any command that \textit{may} return \texttt{VK\_ERROR\_DEVICE\_LOST}, for the purpose of determining whether a command buffer is in the \texttt{pending state}, or whether resources are considered in-use by the device, a return value of \texttt{VK\_ERROR\_DEVICE\_LOST} is equivalent to \texttt{VK\_SUCCESS}.

The content of any external memory objects that have been exported from or imported to a lost device become undefined. Objects on other logical devices or in other APIs which are associated with the same underlying memory resource as the external memory objects on the lost device are unaffected other than their content becoming undefined. The layout of subresources of images on other logical devices that are bound to \texttt{VkDeviceMemory} objects associated with the same underlying memory resources as external memory objects on the lost device becomes \texttt{VK\_IMAGE\_LAYOUT\_UNDEFINED}.

The state of \texttt{VkSemaphore} objects on other logical devices created by importing a semaphore payload with temporary permanence which was exported from the lost device is undefined. The state of \texttt{VkSemaphore} objects on other logical devices that permanently share a semaphore payload with a \texttt{VkSemaphore} object on the lost device is undefined, and remains undefined following any subsequent signal operations. Implementations \textbf{must} ensure pending and subsequently submitted wait operations on such semaphores behave as defined in \texttt{Semaphore State Requirements For Wait Operations} for external semaphores not in a valid state for a wait operation.
4.2.4. Device Destruction

To destroy a device, call:

```c
void vkDestroyDevice(
    VkDevice device, 
    const VkAllocationCallbacks* pAllocator);
```

- `device` is the logical device to destroy.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

To ensure that no work is active on the device, `vkDeviceWaitIdle` can be used to gate the destruction of the device. Prior to destroying a device, an application is responsible for destroying/freeing any Vulkan objects that were created using that device as the first parameter of the corresponding `vkCreate*` or `vkAllocate*` command.

Note

The lifetime of each of these objects is bound by the lifetime of the `VkDevice` object. Therefore, to avoid resource leaks, it is critical that an application explicitly free all of these resources prior to calling `vkDestroyDevice`.

Valid Usage

- All child objects created on `device` must have been destroyed prior to destroying `device`
- If `VkAllocationCallbacks` were provided when `device` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `device` was created, `pAllocator` must be `NULL`

Valid Usage (Implicit)

- If `device` is not `NULL`, `device` must be a valid `VkDevice` handle
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure

Host Synchronization

- Host access to `device` must be externally synchronized
- Host access to all `VkQueue` objects received from `device` must be externally synchronized
4.3. Queues

4.3.1. Queue Family Properties

As discussed in the Physical Device Enumeration section above, the `vkGetPhysicalDeviceQueueFamilyProperties` command is used to retrieve details about the queue families and queues supported by a device.

Each index in the `pQueueFamilyProperties` array returned by `vkGetPhysicalDeviceQueueFamilyProperties` describes a unique queue family on that physical device. These indices are used when creating queues, and they correspond directly with the `queueFamilyIndex` that is passed to the `vkCreateDevice` command via the `VkDeviceQueueCreateInfo` structure as described in the Queue Creation section below.

Grouping of queue families within a physical device is implementation-dependent.

Note

The general expectation is that a physical device groups all queues of matching capabilities into a single family. However, while implementations should do this, it is possible that a physical device may return two separate queue families with the same capabilities.

Once an application has identified a physical device with the queue(s) that it desires to use, it will create those queues in conjunction with a logical device. This is described in the following section.

4.3.2. Queue Creation

Creating a logical device also creates the queues associated with that device. The queues to create are described by a set of `VkDeviceQueueCreateInfo` structures that are passed to `vkCreateDevice` in `pQueueCreateInfos`.

Queues are represented by `VkQueue` handles:

```c
VK_DEFINE_HANDLE(VkQueue)
```

The `VkDeviceQueueCreateInfo` structure is defined as:

```c
typedef struct VkDeviceQueueCreateInfo {
    VkStructureType           sType;
    const void*                pNext;
    VkDeviceQueueCreateFlags  flags;
    uint32_t                   queueFamilyIndex;
    uint32_t                   queueCount;
    const float*               pQueuePriorities;
} VkDeviceQueueCreateInfo;
```

- `sType` is the type of this structure.
• `pNext` is `NULL` or a pointer to an extension-specific structure.

• `flags` is reserved for future use.

• `queueFamilyIndex` is an unsigned integer indicating the index of the queue family to create on this device. This index corresponds to the index of an element of the `pQueueFamilyProperties` array that was returned by `vkGetPhysicalDeviceQueueFamilyProperties`.

• `queueCount` is an unsigned integer specifying the number of queues to create in the queue family indicated by `queueFamilyIndex`.

• `pQueuePriorities` is a pointer to an array of `queueCount` normalized floating point values, specifying priorities of work that will be submitted to each created queue. See Queue Priority for more information.

### Valid Usage

• `queueFamilyIndex` must be less than `pQueueFamilyPropertyCount` returned by `vkGetPhysicalDeviceQueueFamilyProperties`

• `queueCount` must be less than or equal to the `queueCount` member of the `VkQueueFamilyProperties` structure, as returned by `vkGetPhysicalDeviceQueueFamilyProperties` in the `pQueueFamilyProperties[queueFamilyIndex]`

• Each element of `pQueuePriorities` must be between 0.0 and 1.0 inclusive

### Valid Usage (Implicit)

• `sType` must be `VK_STRUCTURE_TYPE_DEVICE_QUEUE_CREATE_INFO`

• `pNext` must be `NULL` or a pointer to a valid instance of `VkDeviceQueueGlobalPriorityCreateInfoEXT`

• The `sType` value of each struct in the `pNext` chain must be unique

• `flags` must be 0

• `pQueuePriorities` must be a valid pointer to an array of `queueCount` `float` values

• `queueCount` must be greater than 0

```c
typedef VkFlags VkDeviceQueueCreateFlags;
```

`VkDeviceQueueCreateFlags` is a bitmask type for setting a mask, but is currently reserved for future use.

A queue can be created with a system-wide priority by adding a `VkDeviceQueueGlobalPriorityCreateInfoEXT` structure to the `pNext` chain of `VkDeviceQueueCreateInfo`.

The `VkDeviceQueueGlobalPriorityCreateInfoEXT` structure is defined as:
typedef struct VkDeviceQueueGlobalPriorityCreateInfoEXT {
    VkStructureType sType;
    const void* pNext;
    VkQueueGlobalPriorityEXT globalPriority;
} VkDeviceQueueGlobalPriorityCreateInfoEXT;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `globalPriority` is the system-wide priority associated to this queue as specified by VkQueueGlobalPriorityEXT

A queue created without specifying `VkDeviceQueueGlobalPriorityCreateInfoEXT` will default to `VK_QUEUE_GLOBAL_PRIORITY_MEDIUM_EXT`.

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_DEVICE_QUEUE_GLOBAL_PRIORITY_CREATE_INFO_EXT`
- `globalPriority` must be a valid `VkQueueGlobalPriorityEXT` value

Possible values of `VkDeviceQueueGlobalPriorityCreateInfoEXT::globalPriority`, specifying a system-wide priority level are:

typedef enum VkQueueGlobalPriorityEXT {
    VK_QUEUE_GLOBAL_PRIORITY_LOW_EXT = 128,
    VK_QUEUE_GLOBAL_PRIORITY_MEDIUM_EXT = 256,
    VK_QUEUE_GLOBAL_PRIORITY_HIGH_EXT = 512,
    VK_QUEUE_GLOBAL_PRIORITY_REALTIME_EXT = 1024,
} VkQueueGlobalPriorityEXT;

Priority values are sorted in ascending order. A comparison operation on the enum values can be used to determine the priority order.

- `VK_QUEUE_GLOBAL_PRIORITY_LOW_EXT` is below the system default. Useful for non-interactive tasks.
- `VK_QUEUE_GLOBAL_PRIORITY_MEDIUM_EXT` is the system default priority.
- `VK_QUEUE_GLOBAL_PRIORITY_HIGH_EXT` is above the system default.
- `VK_QUEUE_GLOBAL_PRIORITY_REALTIME_EXT` is the highest priority. Useful for critical tasks.

Queues with higher system priority may be allotted more processing time than queues with lower priority. An implementation may allow a higher-priority queue to starve a lower-priority queue until the higher-priority queue has no further commands to execute.

Priorities imply no ordering or scheduling constraints.

No specific guarantees are made about higher priority queues receiving more processing time or
better quality of service than lower priority queues.

The global priority level of a queue takes precedence over the per-process queue priority (VkDeviceQueueCreateInfo::pQueuePriorities).

Abuse of this feature may result in starving the rest of the system of implementation resources. Therefore, the driver implementation may deny requests to acquire a priority above the default priority (VK_QUEUE_GLOBAL_PRIORITY_MEDIUM_EXT) if the caller does not have sufficient privileges. In this scenario VK_ERROR_NOT_PERMITTED_EXT is returned.

The driver implementation may fail the queue allocation request if resources required to complete the operation have been exhausted (either by the same process or a different process). In this scenario VK_ERROR_INITIALIZATION_FAILED is returned.

To retrieve a handle to a VkQueue object, call:

```c
void vkGetDeviceQueue(
    VkDevice device,
    uint32_t queueFamilyIndex,
    uint32_t queueIndex,
    VkQueue* pQueue);
```

- device is the logical device that owns the queue.
- queueFamilyIndex is the index of the queue family to which the queue belongs.
- queueIndex is the index within this queue family of the queue to retrieve.
- pQueue is a pointer to a VkQueue object that will be filled with the handle for the requested queue.

**Valid Usage**

- queueFamilyIndex must be one of the queue family indices specified when device was created, via the VkDeviceQueueCreateInfo structure
- queueIndex must be less than the number of queues created for the specified queue family index when device was created, via the queueCount member of the VkDeviceQueueCreateInfo structure
- VkDeviceQueueCreateInfo::flags must have been set to zero when device was created

**Valid Usage (Implicit)**

- device must be a valid VkDevice handle
- pQueue must be a valid pointer to a VkQueue handle
4.3.3. Queue Family Index

The queue family index is used in multiple places in Vulkan in order to tie operations to a specific family of queues.

When retrieving a handle to the queue via `vkGetDeviceQueue`, the queue family index is used to select which queue family to retrieve the `VkQueue` handle from as described in the previous section.

When creating a `VkCommandPool` object (see Command Pools), a queue family index is specified in the `VkCommandPoolCreateInfo` structure. Command buffers from this pool can only be submitted on queues corresponding to this queue family.

When creating `VkImage` (see Images) and `VkBuffer` (see Buffers) resources, a set of queue families is included in the `VkImageCreateInfo` and `VkBufferCreateInfo` structures to specify the queue families that can access the resource.

When inserting a `VkBufferMemoryBarrier` or `VkImageMemoryBarrier` (see Pipeline Barriers), a source and destination queue family index is specified to allow the ownership of a buffer or image to be transferred from one queue family to another. See the Resource Sharing section for details.

4.3.4. Queue Priority

Each queue is assigned a priority, as set in the `VkDeviceQueueCreateInfo` structures when creating the device. The priority of each queue is a normalized floating point value between 0.0 and 1.0, which is then translated to a discrete priority level by the implementation. Higher values indicate a higher priority, with 0.0 being the lowest priority and 1.0 being the highest.

Within the same device, queues with higher priority may be allotted more processing time than queues with lower priority. The implementation makes no guarantees with regards to ordering or scheduling among queues with the same priority, other than the constraints defined by any explicit synchronization primitives. The implementation make no guarantees with regards to queues across different devices.

An implementation may allow a higher-priority queue to starve a lower-priority queue on the same `VkDevice` until the higher-priority queue has no further commands to execute. The relationship of queue priorities must not cause queues on one `VkDevice` to starve queues on another `VkDevice`.

No specific guarantees are made about higher priority queues receiving more processing time or better quality of service than lower priority queues.

4.3.5. Queue Submission

Work is submitted to a queue via queue submission commands such as `vkQueueSubmit`. Queue submission commands define a set of queue operations to be executed by the underlying physical device, including synchronization with semaphores and fences.

Submission commands take as parameters a target queue, zero or more batches of work, and an optional fence to signal upon completion. Each batch consists of three distinct parts:

1. Zero or more semaphores to wait on before execution of the rest of the batch.
- If present, these describe a semaphore wait operation.

2. Zero or more work items to execute.
   - If present, these describe a queue operation matching the work described.

3. Zero or more semaphores to signal upon completion of the work items.
   - If present, these describe a semaphore signal operation.

If a fence is present in a queue submission, it describes a fence signal operation.

All work described by a queue submission command must be submitted to the queue before the command returns.

**Sparse Memory Binding**

In Vulkan it is possible to sparsely bind memory to buffers and images as described in the Sparse Resource chapter. Sparse memory binding is a queue operation. A queue whose flags include the VK_QUEUE_SPARSE_BINDING_BIT must be able to support the mapping of a virtual address to a physical address on the device. This causes an update to the page table mappings on the device. This update must be synchronized on a queue to avoid corrupting page table mappings during execution of graphics commands. By binding the sparse memory resources on queues, all commands that are dependent on the updated bindings are synchronized to only execute after the binding is updated. See the Synchronization and Cache Control chapter for how this synchronization is accomplished.

### 4.3.6. Queue Destruction

Queues are created along with a logical device during vkCreateDevice. All queues associated with a logical device are destroyed when vkDestroyDevice is called on that device.
Chapter 5. Command Buffers

Command buffers are objects used to record commands which can be subsequently submitted to a device queue for execution. There are two levels of command buffers – primary command buffers, which can execute secondary command buffers, and which are submitted to queues, and secondary command buffers, which can be executed by primary command buffers, and which are not directly submitted to queues.

Command buffers are represented by VkCommandBuffer handles:

```
VK_DEFINE_HANDLE(VkCommandBuffer)
```

Recorded commands include commands to bind pipelines and descriptor sets to the command buffer, commands to modify dynamic state, commands to draw (for graphics rendering), commands to dispatch (for compute), commands to execute secondary command buffers (for primary command buffers only), commands to copy buffers and images, and other commands.

Each command buffer manages state independently of other command buffers. There is no inheritance of state across primary and secondary command buffers, or between secondary command buffers. When a command buffer begins recording, all state in that command buffer is undefined. When secondary command buffer(s) are recorded to execute on a primary command buffer, the secondary command buffer inherits no state from the primary command buffer, and all state of the primary command buffer is undefined after an execute secondary command buffer command is recorded. There is one exception to this rule - if the primary command buffer is inside a render pass instance, then the render pass and subpass state is not disturbed by executing secondary command buffers. For state dependent commands (such as draws and dispatches), any state consumed by those commands must not be undefined.

Unless otherwise specified, and without explicit synchronization, the various commands submitted to a queue via command buffers may execute in arbitrary order relative to each other, and/or concurrently. Also, the memory side-effects of those commands may not be directly visible to other commands without explicit memory dependencies. This is true within a command buffer, and across command buffers submitted to a given queue. See the synchronization chapter for information on implicit and explicit synchronization between commands.

5.1. Command Buffer Lifecycle

Each command buffer is always in one of the following states:

**Initial**

When a command buffer is allocated, it is in the initial state. Some commands are able to reset a command buffer (or a set of command buffers) back to this state from any of the executable, recording or invalid state. Command buffers in the initial state can only be moved to the recording state, or freed.

**Recording**

vkBeginCommandBuffer changes the state of a command buffer from the initial state to the
Once a command buffer is in the recording state, vkCmd* commands can be used to record to the command buffer.

**Executable**

vkEndCommandBuffer ends the recording of a command buffer, and moves it from the recording state to the executable state. Executable command buffers can be submitted, reset, or recorded to another command buffer.

**Pending**

Queue submission of a command buffer changes the state of a command buffer from the executable state to the pending state. Whilst in the pending state, applications must not attempt to modify the command buffer in any way - as the device may be processing the commands recorded to it. Once execution of a command buffer completes, the command buffer either reverts back to the executable state, or if it was recorded with VK_COMMAND_BUFFER_USAGE_ONE_TIME_SUBMIT_BIT, it moves to the invalid state. A synchronization command should be used to detect when this occurs.

**Invalid**

Some operations, such as modifying or deleting a resource that was used in a command recorded to a command buffer, will transition the state of that command buffer into the invalid state. Command buffers in the invalid state can only be reset or freed.

![Figure 1. Lifecycle of a command buffer](image)

Any given command that operates on a command buffer has its own requirements on what state a command buffer must be in, which are detailed in the valid usage constraints for that command.

Resetting a command buffer is an operation that discards any previously recorded commands and puts a command buffer in the initial state. Resetting occurs as a result of vkResetCommandBuffer or vkResetCommandPool, or as part of vkBeginCommandBuffer (which additionally puts the command buffer in the recording state).

Secondary command buffers can be recorded to a primary command buffer via vkCmdExecuteCommands. This partially ties the lifecycle of the two command buffers together - if the primary is submitted to a queue, both the primary and any secondaries recorded to it move to the pending state. Once execution of the primary completes, so it does for any secondary recorded
within it. After all executions of each command buffer complete, they each move to their appropriate completion state (either to the *execution state* or the *invalid state*, as specified above).

If a secondary moves to the *invalid state* or the *initial state*, then all primary buffers it is recorded in move to the *invalid state*. A primary moving to any other state does not affect the state of a secondary recorded in it.

<table>
<thead>
<tr>
<th>Note</th>

<tbody>
<tr>
<td>Resetting or freeing a primary command buffer removes the lifecycle linkage to all secondary command buffers that were recorded into it.</td>
</tr>
</tbody>
</table>

### 5.2. Command Pools

Command pools are opaque objects that command buffer memory is allocated from, and which allow the implementation to amortize the cost of resource creation across multiple command buffers. Command pools are externally synchronized, meaning that a command pool **must** not be used concurrently in multiple threads. That includes use via recording commands on any command buffers allocated from the pool, as well as operations that allocate, free, and reset command buffers or the pool itself.

Command pools are represented by *VkCommandPool* handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkCommandPool)
```

To create a command pool, call:

```c
VkResult vkCreateCommandPool(
    VkDevice                                    device,
    const VkCommandPoolCreateInfo*              pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkCommandPool*                              pCommandPool);
```

- **device** is the logical device that creates the command pool.
- **pCreateInfo** is a pointer to a *VkCommandPoolCreateInfo* structure specifying the state of the command pool object.
- **pAllocator** controls host memory allocation as described in the *Memory Allocation* chapter.
- **pCommandPool** is a pointer to a *VkCommandPool* handle in which the created pool is returned.

**Valid Usage**

- **pCreateInfo->queueFamilyIndex** **must** be the index of a queue family available in the logical device **device**
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pCreateInfo** must be a valid pointer to a valid `VkCommandPoolCreateInfo` structure
- If **pAllocator** is not **NULL**, **pAllocator** must be a valid pointer to a valid `VkAllocationCallbacks` structure
- **pCommandPool** must be a valid pointer to a `VkCommandPool` handle

Return Codes

**Success**
- `VK_SUCCESS`

**Failure**
- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

The `VkCommandPoolCreateInfo` structure is defined as:

```c
typedef struct VkCommandPoolCreateInfo {
    VkStructureType            sType;
    const void*                 pNext;
    VkCommandPoolCreateFlags    flags;
    uint32_t                    queueFamilyIndex;
} VkCommandPoolCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkCommandPoolCreateFlagBits` indicating usage behavior for the pool and command buffers allocated from it.
- **queueFamilyIndex** designates a queue family as described in section *Queue Family Properties*. All command buffers allocated from this command pool must be submitted on queues from the same queue family.

Valid Usage
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_COMMAND_POOL_CREATE_INFO`
- `pNext` must be `NULL`
- `flags` must be a valid combination of `VkCommandPoolCreateFlagBits` values

Bits which can be set in `VkCommandPoolCreateInfo::flags` to specify usage behavior for a command pool are:

```c
typedef enum VkCommandPoolCreateFlagBits {
    VK_COMMAND_POOL_CREATE_TRANSIENT_BIT = 0x00000001,
    VK_COMMAND_POOL_CREATE_RESET_COMMAND_BUFFER_BIT = 0x00000002,
} VkCommandPoolCreateFlagBits;
```

- `VK_COMMAND_POOL_CREATE_TRANSIENT_BIT` specifies that command buffers allocated from the pool will be short-lived, meaning that they will be reset or freed in a relatively short timeframe. This flag may be used by the implementation to control memory allocation behavior within the pool.
- `VK_COMMAND_POOL_CREATE_RESET_COMMAND_BUFFER_BIT` allows any command buffer allocated from a pool to be individually reset to the initial state; either by calling `vkResetCommandBuffer`, or via the implicit reset when calling `vkBeginCommandBuffer`. If this flag is not set on a pool, then `vkResetCommandBuffer` must not be called for any command buffer allocated from that pool.

```c
typedef VkFlags VkCommandPoolCreateFlags;
```

`VkCommandPoolCreateFlags` is a bitmask type for setting a mask of zero or more `VkCommandPoolCreateFlagBits`.

To trim a command pool, call:

```c
void vkTrimCommandPoolKHR(
    VkDevice device,    // device which owns the command pool.
    VkCommandPool commandPool, // command pool to trim.
    VkCommandPoolTrimFlags flags); // flags are reserved for future use.
```

- `device` is the logical device that owns the command pool.
- `commandPool` is the command pool to trim.
- `flags` is reserved for future use.

Trimming a command pool recycles unused memory from the command pool back to the system. Command buffers allocated from the pool are not affected by the command.
Note

This command provides applications with some control over the internal memory allocations used by command pools.

Unused memory normally arises from command buffers that have been recorded and later reset, such that they are no longer using the memory. On reset, a command buffer can return memory to its command pool, but the only way to release memory from a command pool to the system requires calling `vkResetCommandPool`, which cannot be executed while any command buffers from that pool are still in use. Subsequent recording operations into command buffers will re-use this memory but since total memory requirements fluctuate over time, unused memory can accumulate.

In this situation, trimming a command pool may be useful to return unused memory back to the system, returning the total outstanding memory allocated by the pool back to a more “average” value.

Implementations utilize many internal allocation strategies that make it impossible to guarantee that all unused memory is released back to the system. For instance, an implementation of a command pool may involve allocating memory in bulk from the system and sub-allocating from that memory. In such an implementation any live command buffer that holds a reference to a bulk allocation would prevent that allocation from being freed, even if only a small proportion of the bulk allocation is in use.

In most cases trimming will result in a reduction in allocated but unused memory, but it does not guarantee the “ideal” behavior.

Trimming may be an expensive operation, and should not be called frequently. Trimming should be treated as a way to relieve memory pressure after application-known points when there exists enough unused memory that the cost of trimming is “worth” it.

Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **commandPool** must be a valid `VkCommandPool` handle
- **flags** must be 0
- **commandPool** must have been created, allocated, or retrieved from `device`

Host Synchronization

- Host access to **commandPool** must be externally synchronized
typedef VkFlags VkCommandPoolTrimFlags;

or the equivalent

typedef VkCommandPoolTrimFlags VkCommandPoolTrimFlagsKHR;

VkCommandPoolTrimFlags is a bitmask type for setting a mask, but is currently reserved for future use.

To reset a command pool, call:

```
VkResult vkResetCommandPool(
    VkDevice device,    
    VkCommandPool commandPool,  
    VkCommandPoolResetFlags flags);
```

- **device** is the logical device that owns the command pool.
- **commandPool** is the command pool to reset.
- **flags** is a bitmask of VkCommandPoolResetFlagBits controlling the reset operation.

Resetting a command pool recycles all of the resources from all of the command buffers allocated from the command pool back to the command pool. All command buffers that have been allocated from the command pool are put in the initial state.

Any primary command buffer allocated from another VkCommandPool that is in the recording or executable state and has a secondary command buffer allocated from commandPool recorded into it, becomes invalid.

### Valid Usage

- All VkCommandBuffer objects allocated from commandPool must not be in the pending state.

### Valid Usage (Implicit)

- device must be a valid VkDevice handle
- commandPool must be a valid VkCommandPool handle
- flags must be a valid combination of VkCommandPoolResetFlagBits values
- commandPool must have been created, allocated, or retrieved from device
Host Synchronization

- Host access to commandPool must be externally synchronized

Return Codes

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

Bits which can be set in vkResetCommandPool::flags to control the reset operation are:

```c
typedef enum VkCommandPoolResetFlagBits {
    VK_COMMAND_POOL_RESET_RELEASE_RESOURCES_BIT = 0x00000001,
} VkCommandPoolResetFlagBits;
```

- **VK_COMMAND_POOL_RESET_RELEASE_RESOURCES_BIT** specifies that resetting a command pool recycles all of the resources from the command pool back to the system.

```c
typedef VkFlags VkCommandPoolResetFlags;
```

VkCommandPoolResetFlags is a bitmask type for setting a mask of zero or more VkCommandPoolResetFlagBits.

To destroy a command pool, call:

```c
void vkDestroyCommandPool(
    VkDevice device,              // device
    VkCommandPool commandPool,    // commandPool
    const VkAllocationCallbacks* pAllocator);  // pAllocator
```

- **device** is the logical device that destroys the command pool.
- **commandPool** is the handle of the command pool to destroy.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.

When a pool is destroyed, all command buffers allocated from the pool are freed.

Any primary command buffer allocated from another VkCommandPool that is in the recording or executable state and has a secondary command buffer allocated from commandPool recorded into it, becomes invalid.
Valid Usage

- All `VkCommandBuffer` objects allocated from `commandPool` must not be in the `pending state`
- If `VkAllocationCallbacks` were provided when `commandPool` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `commandPool` was created, `pAllocator` must be `NULL`

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- If `commandPool` is not `VK_NULL_HANDLE`, `commandPool` must be a valid `VkCommandPool` handle
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- If `commandPool` is a valid handle, it must have been created, allocated, or retrieved from `device`

Host Synchronization

- Host access to `commandPool` must be externally synchronized

5.3. Command Buffer Allocation and Management

To allocate command buffers, call:

```c
VkResult vkAllocateCommandBuffers(
    VkDevice                                    device,
    const VkCommandBufferAllocateInfo*          pAllocateInfo,
    VkCommandBuffer*                            pCommandBuffers);
```

- `device` is the logical device that owns the command pool.
- `pAllocateInfo` is a pointer to a `VkCommandBufferAllocateInfo` structure describing parameters of the allocation.
- `pCommandBuffers` is a pointer to an array of `VkCommandBuffer` handles in which the resulting command buffer objects are returned. The array must be at least the length specified by the `commandBufferCount` member of `pAllocateInfo`. Each allocated command buffer begins in the initial state.

`vkAllocateCommandBuffers` can be used to create multiple command buffers. If the creation of any of those command buffers fails, the implementation must destroy all successfully created command...
buffer objects from this command, set all entries of the pCommandBuffers array to NULL and return the error.

When command buffers are first allocated, they are in the initial state.

Valid Usage (Implicit)

- device must be a valid VkDevice handle
- pAllocateInfo must be a valid pointer to a valid VkCommandBufferAllocateInfo structure
- pCommandBuffers must be a valid pointer to an array of pAllocateInfo->commandBufferCount VkCommandBuffer handles
- The value referenced by pAllocateInfo->commandBufferCount must be greater than 0

Host Synchronization

- Host access to pAllocateInfo->commandPool must be externally synchronized

Return Codes

Success

- VK_SUCCESS

Failure

- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

The VkCommandBufferAllocateInfo structure is defined as:

```c
typedef struct VkCommandBufferAllocateInfo {
    VkStructureType         sType;
    const void*             pNext;
    VkCommandPool           commandPool;
    VkCommandBufferLevel    level;
    uint32_t                commandBufferCount;
} VkCommandBufferAllocateInfo;
```

- sType is the type of this structure.
- pNext is NULL or a pointer to an extension-specific structure.
- commandPool is the command pool from which the command buffers are allocated.
- level is a VkCommandBufferLevel value specifying the command buffer level.
- commandBufferCount is the number of command buffers to allocate from the pool.
Valid Usage

• commandBufferCount **must** be greater than 0

Valid Usage (Implicit)

• sType **must** be VK_STRUCTURE_TYPE_COMMAND_BUFFER_ALLOCATE_INFO
• pNext **must** be NULL
• commandPool **must** be a valid VkCommandPool handle
• level **must** be a valid VkCommandBufferLevel value

Possible values of VkCommandBufferAllocateInfo::level, specifying the command buffer level, are:

```c
typedef enum VkCommandBufferLevel {
    VK_COMMAND_BUFFER_LEVEL_PRIMARY = 0,
    VK_COMMAND_BUFFER_LEVEL_SECONDARY = 1,
} VkCommandBufferLevel;
```

• VK_COMMAND_BUFFER_LEVEL_PRIMARY specifies a primary command buffer.
• VK_COMMAND_BUFFER_LEVEL_SECONDARY specifies a secondary command buffer.

To reset command buffers, call:

```c
VkResult vkResetCommandBuffer(
    VkCommandBuffer                             commandBuffer,
    VkCommandBufferResetFlags                   flags);
```

• commandBuffer is the command buffer to reset. The command buffer **can** be in any state other than pending, and is moved into the initial state.
• flags is a bitmask of VkCommandBufferResetFlagBits controlling the reset operation.

Any primary command buffer that is in the recording or executable state and has commandBuffer recorded into it, becomes invalid.

Valid Usage

• commandBuffer **must** not be in the pending state
• commandBuffer **must** have been allocated from a pool that was created with the VK_COMMAND_POOL_CREATE_RESET_COMMAND_BUFFER_BIT
Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `flags` **must** be a valid combination of `VkCommandBufferResetFlagBits` values

Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized

Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

Bits which **can** be set in `vkResetCommandBuffer::flags` to control the reset operation are:

```cpp
typedef enum VkCommandBufferResetFlagBits {
    VK_COMMAND_BUFFER_RESET_RELEASE_RESOURCES_BIT = 0x00000001,
} VkCommandBufferResetFlagBits;
```

- `VK_COMMAND_BUFFER_RESET_RELEASE_RESOURCES_BIT` specifies that most or all memory resources currently owned by the command buffer **should** be returned to the parent command pool. If this flag is not set, then the command buffer **may** hold onto memory resources and reuse them when recording commands. `commandBuffer` is moved to the initial state.

```cpp
typedef VkFlags VkCommandBufferResetFlags;
```

`VkCommandBufferResetFlags` is a bitmask type for setting a mask of zero or more `VkCommandBufferResetFlagBits`.

To free command buffers, call:

```cpp
void vkFreeCommandBuffers(
    VkDevice device,               
    VkCommandPool commandPool,    
    uint32_t commandBufferCount,  
    const VkCommandBuffer* pCommandBuffers);
```
• device is the logical device that owns the command pool.
• commandPool is the command pool from which the command buffers were allocated.
• commandBufferCount is the length of the pCommandBuffers array.
• pCommandBuffers is a pointer to an array of handles of command buffers to free.

Any primary command buffer that is in the recording or executable state and has any element of pCommandBuffers recorded into it, becomes invalid.

### Valid Usage

- All elements of pCommandBuffers must not be in the pending state
- pCommandBuffers must be a valid pointer to an array of commandBufferCount VkCommandBuffer handles, each element of which must either be a valid handle or NULL

### Valid Usage (Implicit)

- device must be a valid VkDevice handle
- commandPool must be a valid VkCommandPool handle
- commandBufferCount must be greater than 0
- commandPool must have been created, allocated, or retrieved from device
- Each element of pCommandBuffers that is a valid handle must have been created, allocated, or retrieved from commandPool

### Host Synchronization

- Host access to commandPool must be externally synchronized
- Host access to each member of pCommandBuffers must be externally synchronized

### 5.4. Command Buffer Recording

To begin recording a command buffer, call:

```
VkResult vkBeginCommandBuffer(
    VkCommandBuffer                             commandBuffer,
    const VkCommandBufferBeginInfo*             pBeginInfo);
```

- commandBuffer is the handle of the command buffer which is to be put in the recording state.
- pBeginInfo points to a VkCommandBufferBeginInfo structure defining additional information about how the command buffer begins recording.
Valid Usage

- `commandBuffer` must not be in the recording or pending state
- If `commandBuffer` was allocated from a `VkCommandPool` which did not have the `VK_COMMAND_POOL_CREATE_RESET_COMMAND_BUFFER_BIT` flag set, `commandBuffer` must be in the initial state
- If `commandBuffer` is a secondary command buffer, the `pInheritanceInfo` member of `pBeginInfo` must be a valid `VkCommandBufferInheritanceInfo` structure
- If `commandBuffer` is a secondary command buffer and either the `occlusionQueryEnable` member of the `pInheritanceInfo` member of `pBeginInfo` is `VK_FALSE`, or the precise occlusion queries feature is not enabled, the `queryFlags` member of the `pInheritanceInfo` member `pBeginInfo` must not contain `VK_QUERY_CONTROL_PRECISE_BIT`
- If `commandBuffer` is a primary command buffer, then `pBeginInfo->flags` must not set both the `VK_COMMAND_BUFFER_USAGE_ONE_TIME_SUBMIT_BIT` and the `VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT` flags

Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `pBeginInfo` must be a valid pointer to a valid `VkCommandBufferBeginInfo` structure

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Return Codes

Success

- `VK_SUCCESS`

Failure

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

The `VkCommandBufferBeginInfo` structure is defined as:
```c
typedef struct VkCommandBufferBeginInfo {
    VkStructureType                          sType;
    const void*                              pNext;
    VkCommandBufferUsageFlags                flags;
    const VkCommandBufferInheritanceInfo*    pInheritanceInfo;
} VkCommandBufferBeginInfo;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkCommandBufferUsageFlagBits` specifying usage behavior for the command buffer.
- **pInheritanceInfo** is a pointer to a `VkCommandBufferInheritanceInfo` structure, used if `commandBuffer` is a secondary command buffer. If this is a primary command buffer, then this value is ignored.

### Valid Usage

- If **flags** contains `VK_COMMAND_BUFFER_USAGE_RENDER_PASS_CONTINUE_BIT`, the `renderPass` member of `pInheritanceInfo` **must** be a valid `VkRenderPass`.
- If **flags** contains `VK_COMMAND_BUFFER_USAGE_RENDER_PASS_CONTINUE_BIT`, the `subpass` member of `pInheritanceInfo` **must** be a valid subpass index within the `renderPass` member of `pInheritanceInfo`.
- If **flags** contains `VK_COMMAND_BUFFER_USAGE_RENDER_PASS_CONTINUE_BIT`, the `framebuffer` member of `pInheritanceInfo` **must** be either `VK_NULL_HANDLE`, or a valid `VkFramebuffer` that is compatible with the `renderPass` member of `pInheritanceInfo`.

### Valid Usage (Implicit)

- **sType** **must** be `VK_STRUCTURE_TYPE_COMMAND_BUFFER_BEGIN_INFO`.
- **pNext** **must** be **NULL** or a pointer to a valid instance of `VkDeviceGroupCommandBufferBeginInfo`.
- The **sType** value of each struct in the **pNext** chain **must** be unique.
- **flags** **must** be a valid combination of `VkCommandBufferUsageFlagBits` values.

Bits which **can** be set in `VkCommandBufferBeginInfo::flags` to specify usage behavior for a command buffer are:
typedef enum VkCommandBufferUsageFlagBits {
    VK_COMMAND_BUFFER_USAGE_ONE_TIME_SUBMIT_BIT = 0x00000001,
    VK_COMMAND_BUFFER_USAGE_RENDER_PASS_CONTINUE_BIT = 0x00000002,
    VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT = 0x00000004,
} VkCommandBufferUsageFlagBits;

- **VK_COMMAND_BUFFER_USAGE_ONE_TIME_SUBMIT_BIT** specifies that each recording of the command buffer will only be submitted once, and the command buffer will be reset and recorded again between each submission.

- **VK_COMMAND_BUFFER_USAGE_RENDER_PASS_CONTINUE_BIT** specifies that a secondary command buffer is considered to be entirely inside a render pass. If this is a primary command buffer, then this bit is ignored.

- **VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT** specifies that a command buffer can be resubmitted to a queue while it is in the *pending state*, and recorded into multiple primary command buffers.

typedef VkFlags VkCommandBufferUsageFlags;

**VkCommandBufferUsageFlags** is a bitmask type for setting a mask of zero or more **VkCommandBufferUsageFlagBits**.

If the command buffer is a secondary command buffer, then the **VkCommandBufferInheritanceInfo** structure defines any state that will be inherited from the primary command buffer:

typedef struct VkCommandBufferInheritanceInfo {
    VkStructureType sType;
    const void* pNext;
    VkRenderPass renderPass;
    uint32_t subpass;
    VkFramebuffer framebuffer;
    VkBool32 occlusionQueryEnable;
    VkQueryControlFlags queryFlags;
    VkQueryPipelineStatisticFlags pipelineStatistics;
} VkCommandBufferInheritanceInfo;

- **sType** is the type of this structure.

- **pNext** is NULL or a pointer to an extension-specific structure.

- **renderPass** is a **VkRenderPass** object defining which render passes the **VkCommandBuffer** will be compatible with and can be executed within. If the **VkCommandBuffer** will not be executed within a render pass instance, **renderPass** is ignored.

- **subpass** is the index of the subpass within the render pass instance that the **VkCommandBuffer** will be executed within. If the **VkCommandBuffer** will not be executed within a render pass instance, **subpass** is ignored.

- **framebuffer** optionally refers to the **VkFramebuffer** object that the **VkCommandBuffer** will be...
rendering to if it is executed within a render pass instance. It can be VK_NULL_HANDLE if the framebuffer is not known, or if the VkCommandBuffer will not be executed within a render pass instance.

Note
Specifying the exact framebuffer that the secondary command buffer will be executed with may result in better performance at command buffer execution time.

- occlusionQueryEnable specifies whether the command buffer can be executed while an occlusion query is active in the primary command buffer. If this is VK_TRUE, then this command buffer can be executed whether the primary command buffer has an occlusion query active or not. If this is VK_FALSE, then the primary command buffer must not have an occlusion query active.

- queryFlags specifies the query flags that can be used by an active occlusion query in the primary command buffer when this secondary command buffer is executed. If this value includes the VK_QUERY_CONTROL_PRECISE_BIT bit, then the active query can return boolean results or actual sample counts. If this bit is not set, then the active query must not use the VK_QUERY_CONTROL_PRECISE_BIT bit.

- pipelineStatistics is a bitmask of VkQueryPipelineStatisticFlagBits specifying the set of pipeline statistics that can be counted by an active query in the primary command buffer when this secondary command buffer is executed. If this value includes a given bit, then this command buffer can be executed whether the primary command buffer has a pipeline statistics query active that includes this bit or not. If this value excludes a given bit, then the active pipeline statistics query must not be from a query pool that counts that statistic.

Valid Usage

- If the inherited queries feature is not enabled, occlusionQueryEnable must be VK_FALSE
- If the inherited queries feature is enabled, queryFlags must be a valid combination of VkQueryControlFlagBits values
- If the inherited queries feature is not enabled, queryFlags must be 0
- If the pipeline statistics queries feature is enabled, pipelineStatistics must be a valid combination of VkQueryPipelineStatisticFlagBits values
- If the pipeline statistics queries feature is not enabled, pipelineStatistics must be 0
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_COMMAND_BUFFER_INHERITANCE_INFO`
- Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkCommandBufferInheritanceConditionalRenderingInfoEXT` or `VkCommandBufferInheritanceRenderPassTransformInfoQCOM`
- The **sType** value of each struct in the `pNext` chain must be unique
- Both of `framebuffer`, and `renderPass` that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`

**Note**

On some implementations, not using the `VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT` bit enables command buffers to be patched in-place if needed, rather than creating a copy of the command buffer.

If a command buffer is in the invalid, or executable state, and the command buffer was allocated from a command pool with the `VK_COMMAND_POOL_CREATE_RESET_COMMAND_BUFFER_BIT` flag set, then `vkBeginCommandBuffer` implicitly resets the command buffer, behaving as if `vkResetCommandBuffer` had been called with `VK_COMMAND_BUFFER_RESET_RELEASE_RESOURCES_BIT` not set. After the implicit reset, `commandBuffer` is moved to the recording state.

If the `pNext` chain of `VkCommandBufferInheritanceInfo` includes a `VkCommandBufferInheritanceConditionalRenderingInfoEXT` structure, then that structure controls whether a command buffer can be executed while conditional rendering is active in the primary command buffer.

The `VkCommandBufferInheritanceConditionalRenderingInfoEXT` structure is defined as:

```markdown
typedef struct VkCommandBufferInheritanceConditionalRenderingInfoEXT {
    VkStructureType     sType;
    const void*         pNext;
    VkBool32            conditionalRenderingEnable;
} VkCommandBufferInheritanceConditionalRenderingInfoEXT;
```

- **sType** is the type of this structure
- **pNext** is `NULL` or a pointer to an extension-specific structure
- **conditionalRenderingEnable** specifies whether the command buffer can be executed while conditional rendering is active in the primary command buffer. If this is `VK_TRUE`, then this command buffer can be executed whether the primary command buffer has active conditional rendering or not. If this is `VK_FALSE`, then the primary command buffer must not have conditional rendering active.

If this structure is not present, the behavior is as if `conditionalRenderingEnable` is `VK_FALSE`. 

---

122 | Chapter 5. Command Buffers
Valid Usage

- If the **inherited conditional rendering** feature is not enabled, **conditionalRenderingEnable** must be **VK_FALSE**

Valid Usage (Implicit)

- **sType** must be **VK_STRUCTURE_TYPE_COMMAND_BUFFER_INHERITANCE_CONDITIONAL_RENDERING_INFO_EXT**

To begin recording a secondary command buffer compatible with execution inside a render pass using **render pass transform**, add the **VkCommandBufferInheritanceRenderPassTransformInfoQCOM** to the **pNext** chain of **VkCommandBufferInheritanceInfo** structure passed to the **vkBeginCommandBuffer** command specifying the parameters for transformed rasterization.

The **VkCommandBufferInheritanceRenderPassTransformInfoQCOM** structure is defined as:

```c
typedef struct VkCommandBufferInheritanceRenderPassTransformInfoQCOM {
    VkStructureType                  sType;
    void*                            pNext;
    VkSurfaceTransformFlagBitsKHR    transform;
    VkRect2D                         renderArea;
} VkCommandBufferInheritanceRenderPassTransformInfoQCOM;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **transform** is a **VkSurfaceTransformFlagBitsKHR** value describing the transform to be applied to the render pass.
- **renderArea** is the render area that is affected by the command buffer.

When the secondary is recorded to execute within a render pass instance using **vkCmdExecuteCommands**, the render pass transform parameters of the secondary command buffer must be consistent with the render pass transform parameters specified for the render pass instance. In particular, the **transform** and **renderArea** for command buffer must be identical to the **transform** and **renderArea** of the render pass instance.

Valid Usage

- **transform** must be **VK_SURFACE_TRANSFORM_IDENTITY_BIT_KHR**, **VK_SURFACE_TRANSFORM_ROTATE_90_BIT_KHR**, **VK_SURFACE_TRANSFORM_ROTATE_180_BIT_KHR**, or **VK_SURFACE_TRANSFORM_ROTATE_270_BIT_KHR**
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_COMMAND_BUFFER_INHERITANCE_RENDER_PASS_TRANSFORM_INFO_QCOM`

Once recording starts, an application records a sequence of commands (`vkCmd*`) to set state in the command buffer, draw, dispatch, and other commands.

Several commands can also be recorded indirectly from `VkBuffer` content, see Device-Generated Commands.

To complete recording of a command buffer, call:

```c
VkResult vkEndCommandBuffer(
    VkCommandBuffer                             commandBuffer);
```

- `commandBuffer` is the command buffer to complete recording.

If there was an error during recording, the application will be notified by an unsuccessful return code returned by `vkEndCommandBuffer`. If the application wishes to further use the command buffer, the command buffer must be reset. The command buffer must have been in the recording state, and is moved to the executable state.

Valid Usage

- `commandBuffer` must be in the recording state
- If `commandBuffer` is a primary command buffer, there must not be an active render pass instance
- All queries made active during the recording of `commandBuffer` must have been made inactive
- Conditional rendering must not be active
- If `commandBuffer` is a secondary command buffer, there must not be an outstanding `vkCmdBeginDebugUtilsLabelEXT` command recorded to `commandBuffer` that has not previously been ended by a call to `vkCmdEndDebugUtilsLabelEXT`
- If `commandBuffer` is a secondary command buffer, there must not be an outstanding `vkCmdDebugMarkerBeginEXT` command recorded to `commandBuffer` that has not previously been ended by a call to `vkCmdDebugMarkerEndEXT`

Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
Host Synchronization

- Host access to `commandBuffer` must be externally synchronized.
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized.

Return Codes

**Success**
- `VK_SUCCESS`

**Failure**
- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

When a command buffer is in the executable state, it can be submitted to a queue for execution.

### 5.5. Command Buffer Submission

To submit command buffers to a queue, call:

```c
VkResult vkQueueSubmit(  
    VkQueue queue,  
    uint32_t submitCount,  
    const VkSubmitInfo* pSubmits,  
    VkFence fence);
```

- `queue` is the queue that the command buffers will be submitted to.
- `submitCount` is the number of elements in the `pSubmits` array.
- `pSubmits` is a pointer to an array of `VkSubmitInfo` structures, each specifying a command buffer submission batch.
- `fence` is an optional handle to a fence to be signaled once all submitted command buffers have completed execution. If `fence` is not `VK_NULL_HANDLE`, it defines a fence signal operation.

**Note**
Submission can be a high overhead operation, and applications should attempt to batch work together into as few calls to `vkQueueSubmit` as possible.

`vkQueueSubmit` is a queue submission command, with each batch defined by an element of `pSubmits`. Batches begin execution in the order they appear in `pSubmits`, but may complete out of order.

Fence and semaphore operations submitted with `vkQueueSubmit` have additional ordering...
constraints compared to other submission commands, with dependencies involving previous and subsequent queue operations. Information about these additional constraints can be found in the semaphore and fence sections of the synchronization chapter.

Details on the interaction of pWaitDstStageMask with synchronization are described in the semaphore wait operation section of the synchronization chapter.

The order that batches appear in pSubmits is used to determine submission order, and thus all the implicit ordering guarantees that respect it. Other than these implicit ordering guarantees and any explicit synchronization primitives, these batches may overlap or otherwise execute out of order.

If any command buffer submitted to this queue is in the executable state, it is moved to the pending state. Once execution of all submissions of a command buffer complete, it moves from the pending state, back to the executable state. If a command buffer was recorded with the VK_COMMAND_BUFFER_USAGE_ONE_TIME_SUBMIT_BIT flag, it instead moves to the invalid state.

If vkQueueSubmit fails, it may return VK_ERROR_OUT_OF_HOST_MEMORY or VK_ERROR_OUT_OF_DEVICE_MEMORY. If it does, the implementation must ensure that the state and contents of any resources or synchronization primitives referenced by the submitted command buffers and any semaphores referenced by pSubmits is unaffected by the call or its failure. If vkQueueSubmit fails in such a way that the implementation is unable to make that guarantee, the implementation must return VK_ERROR_DEVICE_LOST. See Lost Device.
Valid Usage

• If fence is not VK_NULL_HANDLE, fence must be unsignaled

• If fence is not VK_NULL_HANDLE, fence must not be associated with any other queue command that has not yet completed execution on that queue

• Any calls to vkCmdSetEvent, vkCmdResetEvent or vkCmdWaitEvents that have been recorded into any of the command buffer elements of the pCommandBuffers member of any element of pSubmits, must not reference any VkEvent that is referenced by any of those commands in a command buffer that has been submitted to another queue and is still in the pending state

• Any stage flag included in any element of the pWaitDstStageMask member of any element of pSubmits must be a pipeline stage supported by one of the capabilities of queue, as specified in the table of supported pipeline stages

• Each element of the pSignalSemaphores member of any element of pSubmits must be unsignaled when the semaphore signal operation it defines is executed on the device

• When a semaphore wait operation referring to a binary semaphore defined by any element of the pWaitSemaphores member of any element of pSubmits executes on queue, there must be no other queues waiting on the same semaphore

• All elements of the pWaitSemaphores member of all elements of pSubmits created with a VkSemaphoreType of VK_SEMAPHORE_TYPE_BINARY must reference a semaphore signal operation that has been submitted for execution and any semaphore signal operations on which it depends (if any) must have also been submitted for execution

• Each element of the pCommandBuffers member of each element of pSubmits must be in the pending or executable state

• If any element of the pCommandBuffers member of any element of pSubmits was not recorded with the VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT, it must not be in the pending state

• Any secondary command buffers recorded into any element of the pCommandBuffers member of any element of pSubmits must be in the pending or executable state

• If any secondary command buffers recorded into any element of the pCommandBuffers member of any element of pSubmits was not recorded with the VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT, it must not be in the pending state

• Each element of the pCommandBuffers member of each element of pSubmits must have been allocated from a VkCommandPool that was created for the same queue family queue belongs to

• If any element of pSubmits->pCommandBuffers includes a Queue Family Transfer Acquire Operation, there must exist a previously submitted Queue Family Transfer Release Operation on a queue in the queue family identified by the acquire operation, with parameters matching the acquire operation as defined in the definition of such acquire operations, and which happens-before the acquire operation

• If a command recorded into any element of pCommandBuffers was a vkCmdBeginQuery whose queryPool was created with a queryType of VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR, the
profiling lock must have been held continuously on the VkDevice that queue was retrieved from, throughout recording of those command buffers

- Any resource created with VK_SHARING_MODE_EXCLUSIVE that is read by an operation specified by pSubmits must not be owned by any queue family other than the one which queue belongs to, at the time it is executed.

Valid Usage (Implicit)

- queue must be a valid VkQueue handle
- If submitCount is not 0, pSubmits must be a valid pointer to an array of submitCount valid VkSubmitInfo structures
- If fence is not VK_NULL_HANDLE, fence must be a valid VkFence handle
- Both of fence, and queue that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same VkDevice.

Host Synchronization

- Host access to queue must be externally synchronized
- Host access to fence must be externally synchronized

Command Properties

</tbody>
</table>

Return Codes

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_DEVICE_LOST

The VkSubmitInfo structure is defined as:
typedef struct VkSubmitInfo {
    VkStructureType                sType;
    const void*                    pNext;
    uint32_t                       waitSemaphoreCount;
    const VkSemaphore*             pWaitSemaphores;
    const VkPipelineStageFlags*    pWaitDstStageMask;
    uint32_t                       commandBufferCount;
    const VkCommandBuffer*         pCommandBuffers;
    uint32_t                       signalSemaphoreCount;
    const VkSemaphore*             pSignalSemaphores;
} VkSubmitInfo;

• **sType** is the type of this structure.

• **pNext** is NULL or a pointer to an extension-specific structure.

• **waitSemaphoreCount** is the number of semaphores upon which to wait before executing the command buffers for the batch.

• **pWaitSemaphores** is a pointer to an array of VkSemaphore handles upon which to wait before the command buffers for this batch begin execution. If semaphores to wait on are provided, they define a semaphore wait operation.

• **pWaitDstStageMask** is a pointer to an array of pipeline stages at which each corresponding semaphore wait will occur.

• **commandBufferCount** is the number of command buffers to execute in the batch.

• **pCommandBuffers** is a pointer to an array of VkCommandBuffer handles to execute in the batch.

• **signalSemaphoreCount** is the number of semaphores to be signaled once the commands specified in pCommandBuffers have completed execution.

• **pSignalSemaphores** is a pointer to an array of VkSemaphore handles which will be signaled when the command buffers for this batch have completed execution. If semaphores to be signaled are provided, they define a semaphore signal operation.

The order that command buffers appear in pCommandBuffers is used to determine submission order, and thus all the implicit ordering guarantees that respect it. Other than these implicit ordering guarantees and any explicit synchronization primitives, these command buffers may overlap or otherwise execute out of order.
Valid Usage

• Each element of `pCommandBuffers` must not have been allocated with `VK_COMMAND_BUFFER_LEVEL_SECONDARY`

• If the geometry shaders feature is not enabled, each element of `pWaitDstStageMask` must not contain `VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT`

• If the tessellation shaders feature is not enabled, each element of `pWaitDstStageMask` must not contain `VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT` or `VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT`

• Each element of `pWaitDstStageMask` must not include `VK_PIPELINE_STAGE_HOST_BIT`

• If any element of `pWaitSemaphores` or `pSignalSemaphores` was created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE`, then the `pNext` chain must include a `VkTimelineSemaphoreSubmitInfo` structure

• If the `pNext` chain of this structure includes a `VkTimelineSemaphoreSubmitInfo` structure and any element of `pWaitSemaphores` was created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE`, then its `waitSemaphoreValueCount` member must equal `waitSemaphoreCount`

• If the `pNext` chain of this structure includes a `VkTimelineSemaphoreSubmitInfo` structure and any element of `pSignalSemaphores` was created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE`, then its `signalSemaphoreValueCount` member must equal `signalSemaphoreCount`

• For each element of `pSignalSemaphores` created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE` the corresponding element of `VkTimelineSemaphoreSubmitInfo::pSignalSemaphoreValues` must have a value greater than the current value of the semaphore when the semaphore signal operation is executed

• For each element of `pWaitSemaphores` created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE` the corresponding element of `VkTimelineSemaphoreSubmitInfo::pWaitSemaphoreValues` must have a value which does not differ from the current value of the semaphore or the value of any outstanding semaphore wait or signal operation on that semaphore by more than `maxTimelineSemaphoreValueDifference`

• For each element of `pSignalSemaphores` created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE` the corresponding element of `VkTimelineSemaphoreSubmitInfo::pSignalSemaphoreValues` must have a value which does not differ from the current value of the semaphore or the value of any outstanding semaphore wait or signal operation on that semaphore by more than `maxTimelineSemaphoreValueDifference`

• If the mesh shaders feature is not enabled, each element of `pWaitDstStageMask` must not contain `VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV`

• If the task shaders feature is not enabled, each element of `pWaitDstStageMask` must not contain `VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV`
Valid Usage (Implicit)

- **sType** must be **VK_STRUCTURE_TYPE_SUBMIT_INFO**
- Each **pNext** member of any structure (including this one) in the **pNext** chain must be either **NULL** or a pointer to a valid instance of **VkD3D12FenceSubmitInfoKHR**, **VkDeviceGroupSubmitInfo**, **VkTimelineSemaphoreSubmitInfo**, **VkWin32KeyedMutexAcquireReleaseInfoKHR**, or **VkWin32KeyedMutexAcquireReleaseInfoNV**
- The **sType** value of each struct in the **pNext** chain must be unique
- If **waitSemaphoreCount** is not 0, **pWaitSemaphores** must be a valid pointer to an array of **waitSemaphoreCount** valid **VkSemaphore** handles
- If **waitSemaphoreCount** is not 0, **pWaitDstStageMask** must be a valid pointer to an array of **waitSemaphoreCount** valid combinations of **VkPipelineStageFlagBits** values
- Each element of **pWaitDstStageMask** must not be 0
- If **commandBufferCount** is not 0, **pCommandBuffers** must be a valid pointer to an array of **commandBufferCount** valid **VkCommandBuffer** handles
- If **signalSemaphoreCount** is not 0, **pSignalSemaphores** must be a valid pointer to an array of **signalSemaphoreCount** valid **VkSemaphore** handles
- Each of the elements of **pCommandBuffers**, the elements of **pSignalSemaphores**, and the elements of **pWaitSemaphores** that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same **VkDevice**

To specify the values to use when waiting for and signaling semaphores created with a **VkSemaphoreType** of **VK_SEMAPHORE_TYPE_TIMELINE**, add a **VkTimelineSemaphoreSubmitInfo** structure to the **pNext** chain of the **VkSubmitInfo** structure when using **vkQueueSubmit** or the **VkBindSparseInfo** structure when using **vkQueueBindSparse**. The **VkTimelineSemaphoreSubmitInfo** structure is defined as:

```c
typedef struct VkTimelineSemaphoreSubmitInfo {
    VkStructureType sType;
    const void* pNext;
    uint32_t waitSemaphoreValueCount;
    const uint64_t* pWaitSemaphoreValues;
    uint32_t signalSemaphoreValueCount;
    const uint64_t* pSignalSemaphoreValues;
} VkTimelineSemaphoreSubmitInfo;
```

or the equivalent

```c
typedef VkTimelineSemaphoreSubmitInfo VkTimelineSemaphoreSubmitInfoKHR;
```

- **sType** is the type of this structure.
• **pNext** is NULL or a pointer to an extension-specific structure.

• **waitSemaphoreValueCount** is the number of semaphore wait values specified in **pWaitSemaphoreValues**.

• **pWaitSemaphoreValues** is an array of length **waitSemaphoreValueCount** containing values for the corresponding semaphores in **VkSubmitInfo::pWaitSemaphores** to wait for.

• **signalSemaphoreValueCount** is the number of semaphore signal values specified in **pSignalSemaphoreValues**.

• **pSignalSemaphoreValues** is an array of length **signalSemaphoreValueCount** containing values for the corresponding semaphores in **VkSubmitInfo::pSignalSemaphores** to set when signaled.

If the semaphore in **VkSubmitInfo::pWaitSemaphores** or **VkSubmitInfo::pSignalSemaphores** corresponding to an entry in **pWaitSemaphoreValues** or **pSignalSemaphoreValues** respectively was not created with a **VkSemaphoreType** of **VK_SEMAPHORE_TYPE_TIMELINE**, the implementation must ignore the value in the **pWaitSemaphoreValues** or **pSignalSemaphoreValues** entry.

---

**Valid Usage (Implicit)**

- **sType** must be **VK_STRUCTURE_TYPE_TIMELINE_SEMAPHORE_SUBMIT_INFO**

- If **waitSemaphoreValueCount** is not 0, and **pWaitSemaphoreValues** is not NULL, **pWaitSemaphoreValues** must be a valid pointer to an array of **waitSemaphoreValueCount** **uint64_t** values

- If **signalSemaphoreValueCount** is not 0, and **pSignalSemaphoreValues** is not NULL, **pSignalSemaphoreValues** must be a valid pointer to an array of **signalSemaphoreValueCount** **uint64_t** values

To specify the values to use when waiting for and signaling semaphores whose current payload refers to a Direct3D 12 fence, add a **VkD3D12FenceSubmitInfoKHR** structure to the **pNext** chain of the **VkSubmitInfo** structure. The **VkD3D12FenceSubmitInfoKHR** structure is defined as:

```c
typedef struct VkD3D12FenceSubmitInfoKHR {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           waitSemaphoreValuesCount;
    const uint64_t*    pWaitSemaphoreValues;
    uint32_t           signalSemaphoreValuesCount;
    const uint64_t*    pSignalSemaphoreValues;
} VkD3D12FenceSubmitInfoKHR;
```

- **sType** is the type of this structure.

- **pNext** is NULL or a pointer to an extension-specific structure.

- **waitSemaphoreValuesCount** is the number of semaphore wait values specified in **pWaitSemaphoreValues**.

- **pWaitSemaphoreValues** is a pointer to an array of **waitSemaphoreValuesCount** values for the
corresponding semaphores in \texttt{VkSubmitInfo::pWaitSemaphores} to wait for.

- \texttt{signalSemaphoreValuesCount} is the number of semaphore signal values specified in \texttt{pSignalSemaphoreValues}.
- \texttt{pSignalSemaphoreValues} is a pointer to an array of \texttt{signalSemaphoreValuesCount} values for the corresponding semaphores in \texttt{VkSubmitInfo::pSignalSemaphores} to set when signaled.

If the semaphore in \texttt{VkSubmitInfo::pWaitSemaphores} or \texttt{VkSubmitInfo::pSignalSemaphores} corresponding to an entry in \texttt{pWaitSemaphoreValues} or \texttt{pSignalSemaphoreValues} respectively does not currently have a payload referring to a Direct3D 12 fence, the implementation \textbf{must} ignore the value in the \texttt{pWaitSemaphoreValues} or \texttt{pSignalSemaphoreValues} entry.

\begin{quote}
\textit{Note}

As the introduction of the external semaphore handle type \texttt{VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_D3D12_FENCE_BIT} predates that of timeline semaphores, support for importing semaphore payloads from external handles of that type into semaphores created (implicitly or explicitly) with a \texttt{VkSemaphoreType} of \texttt{VK_SEMAPHORE_TYPE_BINARY} is preserved for backwards compatibility. However, applications \textbf{should} prefer importing such handle types into semaphores created with a \texttt{VkSemaphoreType} of \texttt{VK_SEMAPHORE_TYPE_TIMELINE}, and use the \texttt{VkTimelineSemaphoreSubmitInfo} structure instead of the \texttt{VkD3D12FenceSubmitInfoKHR} structure to specify the values to use when waiting for and signaling such semaphores.
\end{quote}

\begin{tabular}{|l|}
\hline
**Valid Usage** \hline
- \texttt{waitSemaphoreValuesCount} \textbf{must} be the same value as \texttt{VkSubmitInfo::waitSemaphoreCount}, where \texttt{VkSubmitInfo} is in the \texttt{pNext} chain of this \texttt{VkD3D12FenceSubmitInfoKHR} structure
- \texttt{signalSemaphoreValuesCount} \textbf{must} be the same value as \texttt{VkSubmitInfo::signalSemaphoreCount}, where \texttt{VkSubmitInfo} is in the \texttt{pNext} chain of this \texttt{VkD3D12FenceSubmitInfoKHR} structure \hline
\end{tabular}

\begin{tabular}{|l|}
\hline
**Valid Usage (Implicit)** \hline
- \texttt{sType} \textbf{must} be \texttt{VK_STRUCTURE_TYPE_D3D12_FENCE_SUBMIT_INFO_KHR}
- If \texttt{waitSemaphoreValuesCount} is not 0, and \texttt{pWaitSemaphoreValues} is not NULL, \texttt{pWaitSemaphoreValues} \textbf{must} be a valid pointer to an array of \texttt{waitSemaphoreValuesCount} uint64_t values
- If \texttt{signalSemaphoreValuesCount} is not 0, and \texttt{pSignalSemaphoreValues} is not NULL, \texttt{pSignalSemaphoreValues} \textbf{must} be a valid pointer to an array of \texttt{signalSemaphoreValuesCount} uint64_t values \hline
\end{tabular}

When submitting work that operates on memory imported from a Direct3D 11 resource to a queue, the keyed mutex mechanism \textbf{may} be used in addition to Vulkan semaphores to synchronize the work. Keyed mutexes are a property of a properly created shareable Direct3D 11 resource. They
can only be used if the imported resource was created with the `D3D11_RESOURCE_MISC_SHARED_KEYEDMUTEX` flag.

To acquire keyed mutexes before submitted work and/or release them after, add a `VkWin32KeyedMutexAcquireReleaseInfoKHR` structure to the `pNext` chain of the `VkSubmitInfo` structure.

The `VkWin32KeyedMutexAcquireReleaseInfoKHR` structure is defined as:

```c
typedef struct VkWin32KeyedMutexAcquireReleaseInfoKHR {
    VkStructureType sType;
    const void* pNext;
    uint32_t acquireCount;
    const VkDeviceMemory* pAcquireSyncs;
    const uint64_t* pAcquireKeys;
    const uint32_t* pAcquireTimeouts;
    uint32_t releaseCount;
    const VkDeviceMemory* pReleaseSyncs;
    const uint64_t* pReleaseKeys;
} VkWin32KeyedMutexAcquireReleaseInfoKHR;
```

- **acquireCount** is the number of entries in the `pAcquireSyncs`, `pAcquireKeys`, and `pAcquireTimeoutMilliseconds` arrays.
- **pAcquireSyncs** is a pointer to an array of `VkDeviceMemory` objects which were imported from Direct3D 11 resources.
- **pAcquireKeys** is a pointer to an array of mutex key values to wait for prior to beginning the submitted work. Entries refer to the keyed mutex associated with the corresponding entries in `pAcquireSyncs`.
- **pAcquireTimeoutMilliseconds** is a pointer to an array of timeout values, in millisecond units, for each acquire specified in `pAcquireKeys`.
- **releaseCount** is the number of entries in the `pReleaseSyncs` and `pReleaseKeys` arrays.
- **pReleaseSyncs** is a pointer to an array of `VkDeviceMemory` objects which were imported from Direct3D 11 resources.
- **pReleaseKeys** is a pointer to an array of mutex key values to set when the submitted work has completed. Entries refer to the keyed mutex associated with the corresponding entries in `pReleaseSyncs`.

### Valid Usage

- Each member of `pAcquireSyncs` and `pReleaseSyncs` must be a device memory object imported by setting `VkImportMemoryWin32HandleInfoKHR::handleType` to `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_BIT` or `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_KMT_BIT`
Valid Usage (Implicit)

- sType must be VK_STRUCTURE_TYPE_WIN32_KEYED_MUTEX_ACQUIRE_RELEASE_INFO_KHR

- If acquireCount is not 0, pAcquireSyncs must be a valid pointer to an array of acquireCount valid VkDeviceMemory handles

- If acquireCount is not 0, pAcquireKeys must be a valid pointer to an array of acquireCount uint64_t values

- If acquireCount is not 0, pAcquireTimeouts must be a valid pointer to an array of acquireCount uint32_t values

- If releaseCount is not 0, pReleaseSyncs must be a valid pointer to an array of releaseCount valid VkDeviceMemory handles

- If releaseCount is not 0, pReleaseKeys must be a valid pointer to an array of releaseCount uint64_t values

- Both of the elements of pAcquireSyncs, and the elements of pReleaseSyncs that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same VkDevice

When submitting work that operates on memory imported from a Direct3D 11 resource to a queue, the keyed mutex mechanism may be used in addition to Vulkan semaphores to synchronize the work. Keyed mutexes are a property of a properly created shareable Direct3D 11 resource. They can only be used if the imported resource was created with the D3D11_RESOURCE_MISC_SHARED_KEYEDMUTEX flag.

To acquire keyed mutexes before submitted work and/or release them after, add a VkWin32KeyedMutexAcquireReleaseInfoNV structure to the pNext chain of the VkSubmitInfo structure.

The VkWin32KeyedMutexAcquireReleaseInfoNV structure is defined as:

```c
typedef struct VkWin32KeyedMutexAcquireReleaseInfoNV {
    VkStructureType          sType;
    const void*              pNext;
    uint32_t                 acquireCount;
    const VkDeviceMemory*    pAcquireSyncs;
    const uint64_t*          pAcquireKeys;
    const uint32_t*          pAcquireTimeoutMilliseconds;
    uint32_t                 releaseCount;
    const VkDeviceMemory*    pReleaseSyncs;
    const uint64_t*          pReleaseKeys;
} VkWin32KeyedMutexAcquireReleaseInfoNV;
```

- acquireCount is the number of entries in the pAcquireSyncs, pAcquireKeys, and pAcquireTimeoutMilliseconds arrays.

- pAcquireSyncs is a pointer to an array of VkDeviceMemory objects which were imported from
Direct3D 11 resources.

- **pAcquireKeys** is a pointer to an array of mutex key values to wait for prior to beginning the submitted work. Entries refer to the keyed mutex associated with the corresponding entries in `pAcquireSyncs`.

- **pAcquireTimeoutMilliseconds** is a pointer to an array of timeout values, in millisecond units, for each acquire specified in **pAcquireKeys**.

- **releaseCount** is the number of entries in the **pReleaseSyncs** and **pReleaseKeys** arrays.

- **pReleaseSyncs** is a pointer to an array of VkDeviceMemory objects which were imported from Direct3D 11 resources.

- **pReleaseKeys** is a pointer to an array of mutex key values to set when the submitted work has completed. Entries refer to the keyed mutex associated with the corresponding entries in `pReleaseSyncs`.

---

**Valid Usage (Implicit)**

- **sType** must be **VK_STRUCTURE_TYPE_WIN32_KEYED_MUTEX_ACQUIRE_RELEASE_INFO_NV**

- If `acquireCount` is not 0, **pAcquireSyncs** must be a valid pointer to an array of `acquireCount` valid VkDeviceMemory handles

- If `acquireCount` is not 0, **pAcquireKeys** must be a valid pointer to an array of `acquireCount` uint64_t values

- If `acquireCount` is not 0, **pAcquireTimeoutMilliseconds** must be a valid pointer to an array of `acquireCount` uint32_t values

- If `releaseCount` is not 0, **pReleaseSyncs** must be a valid pointer to an array of `releaseCount` valid VkDeviceMemory handles

- If `releaseCount` is not 0, **pReleaseKeys** must be a valid pointer to an array of `releaseCount` uint64_t values

- Both of the elements of **pAcquireSyncs**, and the elements of **pReleaseSyncs** that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same VkDevice

If the **pNext** chain of **VkSubmitInfo** includes a **VkDeviceGroupSubmitInfo** structure, then that structure includes device indices and masks specifying which physical devices execute semaphore operations and command buffers.

The **VkDeviceGroupSubmitInfo** structure is defined as:
```c
typedef struct VkDeviceGroupSubmitInfo {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           waitSemaphoreCount;
    const uint32_t*    pWaitSemaphoreDeviceIndices;
    uint32_t           commandBufferCount;
    const uint32_t*    pCommandBufferDeviceMasks;
    uint32_t           signalSemaphoreCount;
    const uint32_t*    pSignalSemaphoreDeviceIndices;
} VkDeviceGroupSubmitInfo;
```

or the equivalent

```c
typedef VkDeviceGroupSubmitInfo VkDeviceGroupSubmitInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **waitSemaphoreCount** is the number of elements in the **pWaitSemaphoreDeviceIndices** array.
- **pWaitSemaphoreDeviceIndices** is a pointer to an array of **waitSemaphoreCount** device indices indicating which physical device executes the semaphore wait operation in the corresponding element of **VkSubmitInfo::pWaitSemaphores**.
- **commandBufferCount** is the number of elements in the **pCommandBufferDeviceMasks** array.
- **pCommandBufferDeviceMasks** is a pointer to an array of **commandBufferCount** device masks indicating which physical devices execute the command buffer in the corresponding element of **VkSubmitInfo::pCommandBuffers**. A physical device executes the command buffer if the corresponding bit is set in the mask.
- **signalSemaphoreCount** is the number of elements in the **pSignalSemaphoreDeviceIndices** array.
- **pSignalSemaphoreDeviceIndices** is a pointer to an array of **signalSemaphoreCount** device indices indicating which physical device executes the semaphore signal operation in the corresponding element of **VkSubmitInfo::pSignalSemaphores**.

If this structure is not present, semaphore operations and command buffers execute on device index zero.
Valid Usage

- `waitSemaphoreCount` **must** equal `VkSubmitInfo::waitSemaphoreCount`
- `commandBufferCount` **must** equal `VkSubmitInfo::commandBufferCount`
- `signalSemaphoreCount` **must** equal `VkSubmitInfo::signalSemaphoreCount`
- All elements of `pWaitSemaphoreDeviceIndices` and `pSignalSemaphoreDeviceIndices` **must** be valid device indices
- All elements of `pCommandBufferDeviceMasks` **must** be valid device masks

Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_DEVICE_GROUP_SUBMIT_INFO`
- If `waitSemaphoreCount` is not 0, `pWaitSemaphoreDeviceIndices` **must** be a valid pointer to an array of `waitSemaphoreCount uint32_t` values
- If `commandBufferCount` is not 0, `pCommandBufferDeviceMasks` **must** be a valid pointer to an array of `commandBufferCount uint32_t` values
- If `signalSemaphoreCount` is not 0, `pSignalSemaphoreDeviceIndices` **must** be a valid pointer to an array of `signalSemaphoreCount uint32_t` values

If the `pNext` chain of `VkSubmitInfo` includes a `VkPerformanceQuerySubmitInfoKHR` structure, then the structure indicates which counter pass is active for the batch in that submit.

The `VkPerformanceQuerySubmitInfoKHR` structure is defined as:

```c
typedef struct VkPerformanceQuerySubmitInfoKHR {
    VkStructureType sType;
    const void* pNext;
    uint32_t counterPassIndex;
} VkPerformanceQuerySubmitInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `counterPassIndex` specifies which counter pass index is active.

If the `VkSubmitInfo::pNext` chain does not include this structure, the batch defaults to use counter pass index 0.
5.6. Queue Forward Progress

When using binary semaphores, the application must ensure that command buffer submissions will be able to complete without any subsequent operations by the application on any queue. After any call to `vkQueueSubmit` (or other queue operation), for every queued wait on a semaphore created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_BINARY` there must be a prior signal of that semaphore that will not be consumed by a different wait on the semaphore.

When using timeline semaphores, wait-before-signal behavior is well-defined and applications can submit work via `vkQueueSubmit` which defines a timeline semaphore wait operation before submitting a corresponding semaphore signal operation. For each timeline semaphore wait operation defined by a call to `vkQueueSubmit`, the application must ensure that a corresponding semaphore signal operation is executed before forward progress can be made.

Command buffers in the submission can include `vkCmdWaitEvents` commands that wait on events that will not be signaled by earlier commands in the queue. Such events must be signaled by the application using `vkSetEvent`, and the `vkCmdWaitEvents` commands that wait upon them must not be inside a render pass instance. The event must be set before the `vkCmdWaitEvents` command is executed.

**Note**

Implementations may have some tolerance for waiting on events to be set, but this is defined outside of the scope of Vulkan.

5.7. Secondary Command Buffer Execution

A secondary command buffer must not be directly submitted to a queue. Instead, secondary command buffers are recorded to execute as part of a primary command buffer with the command:

```c
void vkCmdExecuteCommands(
    VkCommandBuffer commandBuffer,            
    uint32_t commandBufferCount,              
    const VkCommandBuffer*                     
    pCommandBuffers);
```
- `commandBuffer` is a handle to a primary command buffer that the secondary command buffers are executed in.
- `commandBufferCount` is the length of the `pCommandBuffers` array.
- `pCommandBuffers` is a pointer to an array of `commandBufferCount` secondary command buffer handles, which are recorded to execute in the primary command buffer in the order they are listed in the array.

If any element of `pCommandBuffers` was not recorded with the `VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT` flag, and it was recorded into any other primary command buffer which is currently in the executable or recording state, that primary command buffer becomes invalid.
Valid Usage

• Each element of `pCommandBuffers` must have been allocated with a level of `VK_COMMAND_BUFFER_LEVEL_SECONDARY`

• Each element of `pCommandBuffers` must be in the pending or executable state

• If any element of `pCommandBuffers` was not recorded with the `VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT` flag, it must not be in the pending state

• If any element of `pCommandBuffers` was not recorded with the `VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT` flag, it must not have already been recorded to `commandBuffer`

• If any element of `pCommandBuffers` was not recorded with the `VK_COMMAND_BUFFER_USAGE_SIMULTANEOUS_USE_BIT` flag, it must not appear more than once in `pCommandBuffers`

• Each element of `pCommandBuffers` must have been allocated from a `VkCommandPool` that was created for the same queue family as the `VkCommandPool` from which `commandBuffer` was allocated

• If `vkCmdExecuteCommands` is being called within a render pass instance, that render pass instance must have been begun with the `contents` parameter of `vkCmdBeginRenderPass` set to `VK_SUBPASS_CONTENTS_SECONDARY_COMMAND_BUFFERS`

• If `vkCmdExecuteCommands` is being called within a render pass instance, each element of `pCommandBuffers` must have been recorded with the `VK_COMMAND_BUFFER_USAGE_RENDER_PASS_CONTINUE_BIT`

• If `vkCmdExecuteCommands` is being called within a render pass instance, each element of `pCommandBuffers` must have been recorded with `VkCommandBufferInheritanceInfo::subpass` set to the index of the subpass which the given command buffer will be executed in

• If `vkCmdExecuteCommands` is being called within a render pass instance, the render passes specified in the `pBeginInfo->pInheritanceInfo->renderPass` members of the `vkBeginCommandBuffer` commands used to begin recording each element of `pCommandBuffers` must be compatible with the current render pass

• If `vkCmdExecuteCommands` is being called within a render pass instance, and any element of `pCommandBuffers` was recorded with `VkCommandBufferInheritanceInfo::framebuffer` not equal to `VK_NULL_HANDLE`, that `VkFramebuffer` must match the `VkFramebuffer` used in the current render pass instance

• If `vkCmdExecuteCommands` is being called within a render pass instance that included `VkRenderPassTransformBeginInfoQCOM` in the `pNext` chain of `VkRenderPassBeginInfo`, then each element of `pCommandBuffers` must have been recorded with `VkCommandBufferInheritanceRenderPassTransformInfoQCOM` in the `pNext` chain of `VkCommandBufferBeginInfo`

• If `vkCmdExecuteCommands` is being called within a render pass instance that included `VkRenderPassTransformBeginInfoQCOM` in the `pNext` chain of `VkRenderPassBeginInfo`, then each element of `pCommandBuffers` must have been recorded with `VkCommandBufferInheritanceRenderPassTransformInfoQCOM::transform` identical to `VkRenderPassTransformBeginInfoQCOM::transform`
• If `vkCmdExecuteCommands` is being called within a render pass instance that included `VkRenderPassTransformBeginInfoQCOM` in the `pNext` chain of `VkRenderPassBeginInfo`, then each element of `pCommandBuffers` must have been recorded with `VkCommandBufferInheritanceRenderPassTransformInfoQCOM::renderArea` identical to `VkRenderPassBeginInfo::renderArea`.

• If `vkCmdExecuteCommands` is not being called within a render pass instance, each element of `pCommandBuffers` must not have been recorded with the `VK_COMMAND_BUFFER_USAGE_RENDER_PASS_CONTINUE_BIT`.

• If the inherited queries feature is not enabled, `commandBuffer` must not have any queries active.

• If `commandBuffer` has a `VK_QUERY_TYPE_OCCLUSION` query active, then each element of `pCommandBuffers` must have been recorded with `VkCommandBufferInheritanceInfo::occlusionQueryEnable` set to `VK_TRUE`.

• If `commandBuffer` has a `VK_QUERY_TYPE_OCCLUSION` query active, then each element of `pCommandBuffers` must have been recorded with `VkCommandBufferInheritanceInfo::queryFlags` having all bits set that are set for the query.

• If `commandBuffer` has a `VK_QUERY_TYPE_PIPELINE_STATISTICS` query active, then each element of `pCommandBuffers` must have been recorded with `VkCommandBufferInheritanceInfo::pipelineStatistics` having all bits set that are set in the `VkQueryPool` the query uses.

• Each element of `pCommandBuffers` must not begin any query types that are active in `commandBuffer`.

• This command must not be recorded when transform feedback is active.

---

**Valid Usage (Implicit)**

• `commandBuffer` must be a valid `VkCommandBuffer` handle.

• `pCommandBuffers` must be a valid pointer to an array of `commandBufferCount` valid `VkCommandBuffer` handles.

• `commandBuffer` must be in the recording state.

• The `VkCommandPool` that `commandBuffer` was allocated from must support transfer, graphics, or compute operations.

• `commandBuffer` must be a primary `VkCommandBuffer`.

• `commandBufferCount` must be greater than 0.

• Both of `commandBuffer`, and the elements of `pCommandBuffers` must have been created, allocated, or retrieved from the same `VkDevice`.
Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

5.8. Command Buffer Device Mask

Each command buffer has a piece of state storing the current device mask of the command buffer. This mask controls which physical devices within the logical device all subsequent commands will execute on, including state-setting commands, action commands, and synchronization commands.

Scissor, exclusive scissor, and viewport state can be set to different values on each physical device (only when set as dynamic state), and each physical device will render using its local copy of the state. Other state is shared between physical devices, such that all physical devices use the most recently set values for the state. However, when recording an action command that uses a piece of state, the most recent command that set that state must have included all physical devices that execute the action command in its current device mask.

The command buffer's device mask is orthogonal to the `pCommandBufferDeviceMasks` member of `VkDeviceGroupSubmitInfo`. Commands only execute on a physical device if the device index is set in both device masks.

If the `pNext` chain of `VkCommandBufferBeginInfo` includes a `VkDeviceGroupCommandBufferBeginInfo` structure, then that structure includes an initial device mask for the command buffer.

The `VkDeviceGroupCommandBufferBeginInfo` structure is defined as:

```c
typedef struct VkDeviceGroupCommandBufferBeginInfo {
    VkStructureType sType;
    const void* pNext;
    uint32_t deviceMask;
} VkDeviceGroupCommandBufferBeginInfo;
```

or the equivalent
typedef VkDeviceGroupCommandBufferBeginInfo VkDeviceGroupCommandBufferBeginInfoKHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **deviceMask** is the initial value of the command buffer's device mask.

The initial device mask also acts as an upper bound on the set of devices that can ever be in the device mask in the command buffer.

If this structure is not present, the initial value of a command buffer's device mask is set to include all physical devices in the logical device when the command buffer begins recording.

### Valid Usage

- **deviceMask** must be a valid device mask value
- **deviceMask** must not be zero

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_DEVICE_GROUP_COMMAND_BUFFER_BEGIN_INFO`

To update the current device mask of a command buffer, call:

```c
void vkCmdSetDeviceMaskKHR(
    VkCommandBuffer commandBuffer,
    uint32_t deviceMask);
```

- **commandBuffer** is command buffer whose current device mask is modified.
- **deviceMask** is the new value of the current device mask.

**deviceMask** is used to filter out subsequent commands from executing on all physical devices whose bit indices are not set in the mask, except commands beginning a render pass instance, commands transitioning to the next subpass in the render pass instance, and commands ending a render pass instance, which always execute on the set of physical devices whose bit indices are included in the **deviceMask** member of the `VkDeviceGroupRenderPassBeginInfo` structure passed to the command beginning the corresponding render pass instance.
Valid Usage

- `deviceMask` must be a valid device mask value
- `deviceMask` must not be zero
- `deviceMask` must not include any set bits that were not in the `VkDeviceGroupCommandBufferBeginInfo::deviceMask` value when the command buffer began recording
- If `vkCmdSetDeviceMask` is called inside a render pass instance, `deviceMask` must not include any set bits that were not in the `VkDeviceGroupRenderPassBeginInfo::deviceMask` value when the render pass instance began recording

Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics, compute, or transfer operations

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Chapter 6. Synchronization and Cache Control

Synchronization of access to resources is primarily the responsibility of the application in Vulkan. The order of execution of commands with respect to the host and other commands on the device has few implicit guarantees, and needs to be explicitly specified. Memory caches and other optimizations are also explicitly managed, requiring that the flow of data through the system is largely under application control.

Whilst some implicit guarantees exist between commands, five explicit synchronization mechanisms are exposed by Vulkan:

**Fences**

Fences can be used to communicate to the host that execution of some task on the device has completed.

**Semaphores**

Semaphores can be used to control resource access across multiple queues.

**Events**

Events provide a fine-grained synchronization primitive which can be signaled either within a command buffer or by the host, and can be waited upon within a command buffer or queried on the host.

**Pipeline Barriers**

Pipeline barriers also provide synchronization control within a command buffer, but at a single point, rather than with separate signal and wait operations.

**Render Passes**

Render passes provide a useful synchronization framework for most rendering tasks, built upon the concepts in this chapter. Many cases that would otherwise need an application to use other synchronization primitives can be expressed more efficiently as part of a render pass.

### 6.1. Execution and Memory Dependencies

An operation is an arbitrary amount of work to be executed on the host, a device, or an external entity such as a presentation engine. Synchronization commands introduce explicit execution dependencies, and memory dependencies between two sets of operations defined by the command’s two synchronization scopes.

The synchronization scopes define which other operations a synchronization command is able to create execution dependencies with. Any type of operation that is not in a synchronization command’s synchronization scopes will not be included in the resulting dependency. For example, for many synchronization commands, the synchronization scopes can be limited to just operations executing in specific pipeline stages, which allows other pipeline stages to be excluded from a dependency. Other scoping options are possible, depending on the particular command.
An execution dependency is a guarantee that for two sets of operations, the first set must happen-before the second set. If an operation happens-before another operation, then the first operation must complete before the second operation is initiated. More precisely:

- Let A and B be separate sets of operations.
- Let S be a synchronization command.
- Let $A_S$ and $B_S$ be the synchronization scopes of S.
- Let $A'$ be the intersection of sets A and $A_S$.
- Let $B'$ be the intersection of sets B and $B_S$.
- Submitting A, S and B for execution, in that order, will result in execution dependency E between $A'$ and $B'$.
- Execution dependency E guarantees that $A'$ happens-before $B'$.

An execution dependency chain is a sequence of execution dependencies that form a happens-before relation between the first dependency's $A'$ and the final dependency's $B'$. For each consecutive pair of execution dependencies, a chain exists if the intersection of $B_S$ in the first dependency and $A_S$ in the second dependency is not an empty set. The formation of a single execution dependency from an execution dependency chain can be described by substituting the following in the description of execution dependencies:

- Let S be a set of synchronization commands that generate an execution dependency chain.
- Let $A_S$ be the first synchronization scope of the first command in S.
- Let $B_S$ be the second synchronization scope of the last command in S.

Execution dependencies alone are not sufficient to guarantee that values resulting from writes in one set of operations can be read from another set of operations.

Three additional types of operation are used to control memory access. Availability operations cause the values generated by specified memory write accesses to become available to a memory domain for future access. Any available value remains available until a subsequent write to the same memory location occurs (whether it is made available or not) or the memory is freed. Memory domain operations cause writes that are available to a source memory domain to become available to a destination memory domain (an example of this is making writes available to the host domain available to the device domain). Visibility operations cause values available to a memory domain to become visible to specified memory accesses.

Availability, visibility, memory domains, and memory domain operations are formally defined in the Availability and Visibility section of the Memory Model chapter. Which API operations perform each of these operations is defined in Availability, Visibility, and Domain Operations.

A memory dependency is an execution dependency which includes availability and visibility operations such that:

- The first set of operations happens-before the availability operation.
- The availability operation happens-before the visibility operation.
- The visibility operation happens-before the second set of operations.
Once written values are made visible to a particular type of memory access, they can be read or written by that type of memory access. Most synchronization commands in Vulkan define a memory dependency.

The specific memory accesses that are made available and visible are defined by the access scopes of a memory dependency. Any type of access that is in a memory dependency's first access scope and occurs in \( A' \) is made available. Any type of access that is in a memory dependency's second access scope and occurs in \( B' \) has any available writes made visible to it. Any type of operation that is not in a synchronization command's access scopes will not be included in the resulting dependency.

A memory dependency enforces availability and visibility of memory accesses and execution order between two sets of operations. Adding to the description of execution dependency chains:

- Let \( a \) be the set of memory accesses performed by \( A' \).
- Let \( b \) be the set of memory accesses performed by \( B' \).
- Let \( a_s \) be the first access scope of the first command in \( S \).
- Let \( b_s \) be the second access scope of the last command in \( S \).
- Let \( a' \) be the intersection of sets \( a \) and \( a_s \).
- Let \( b' \) be the intersection of sets \( b \) and \( b_s \).
- Submitting \( A, S \) and \( B \) for execution, in that order, will result in a memory dependency \( m \) between \( A' \) and \( B' \).
- Memory dependency \( m \) guarantees that:
  - Memory writes in \( a' \) are made available.
  - Available memory writes, including those from \( a' \), are made visible to \( b' \).

**Note**

Execution and memory dependencies are used to solve data hazards, i.e. to ensure that read and write operations occur in a well-defined order. Write-after-read hazards can be solved with just an execution dependency, but read-after-write and write-after-write hazards need appropriate memory dependencies to be included between them. If an application does not include dependencies to solve these hazards, the results and execution orders of memory accesses are undefined.

### 6.1.1. Image Layout Transitions

Image subresources can be transitioned from one layout to another as part of a memory dependency (e.g. by using an image memory barrier). When a layout transition is specified in a memory dependency, it happens-after the availability operations in the memory dependency, and happens-before the visibility operations. Image layout transitions may perform read and write accesses on all memory bound to the image subresource range, so applications must ensure that all memory writes have been made available before a layout transition is executed. Available memory is automatically made visible to a layout transition, and writes performed by a layout transition are automatically made available.
Layout transitions always apply to a particular image subresource range, and specify both an old layout and new layout. If the old layout does not match the new layout, a transition occurs. The old layout must match the current layout of the image subresource range, with one exception. The old layout can always be specified as `VK_IMAGE_LAYOUT_UNDEFINED`, though doing so invalidates the contents of the image subresource range.

### Note
Setting the old layout to `VK_IMAGE_LAYOUT_UNDEFINED` implies that the contents of the image subresource need not be preserved. Implementations may use this information to avoid performing expensive data transition operations.

As image layout transitions may perform read and write accesses on the memory bound to the image, if the image subresource affected by the layout transition is bound to peer memory for any device in the current device mask then the memory heap the bound memory comes from must support the `VK_PEER_MEMORY_FEATURE_GENERIC_SRC_BIT` and `VK_PEER_MEMORY_FEATURE_GENERIC_DST_BIT` capabilities as returned by `vkGetDeviceGroupPeerMemoryFeatures`.

### Note
Applications must ensure that layout transitions happen-after all operations accessing the image with the old layout, and happen-before any operations that will access the image with the new layout. Layout transitions are potentially read/write operations, so not defining appropriate memory dependencies to guarantee this will result in a data race.

Image layout transitions interact with memory aliasing.

### 6.1.2. Pipeline Stages

The work performed by an action or synchronization command consists of multiple operations, which are performed as a sequence of logically independent steps known as pipeline stages. The exact pipeline stages executed depend on the particular command that is used, and current command buffer state when the command was recorded. Drawing commands, dispatching commands, copy commands, clear commands, and synchronization commands all execute in different sets of pipeline stages. Synchronization commands do not execute in a defined pipeline, but do execute `VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT` and `VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT`.

### Note
Operations performed by synchronization commands (e.g. availability and visibility operations) are not executed by a defined pipeline stage. However other commands can still synchronize with them via the `VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT` and `VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT` pipeline stages.

Execution of operations across pipeline stages must adhere to implicit ordering guarantees, particularly including pipeline stage order. Otherwise, execution across pipeline stages may overlap or execute out of order with regards to other stages, unless otherwise enforced by an execution dependency.
Several of the synchronization commands include pipeline stage parameters, restricting the synchronization scopes for that command to just those stages. This allows fine grained control over the exact execution dependencies and accesses performed by action commands. Implementations should use these pipeline stages to avoid unnecessary stalls or cache flushing.

Bits which can be set, specifying pipeline stages, are:

```c
typedef enum VkPipelineStageFlagBits {
    VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT = 0x00000001,
    VK_PIPELINE_STAGE_DRAW_INDIRECT_BIT = 0x00000002,
    VK_PIPELINE_STAGE_VERTEX_INPUT_BIT = 0x00000004,
    VK_PIPELINE_STAGE_VERTEX_SHADER_BIT = 0x00000008,
    VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT = 0x00000010,
    VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT = 0x00000020,
    VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT = 0x00000040,
    VK_PIPELINE_STAGE_FRAGMENT_SHADER_BIT = 0x00000080,
    VK_PIPELINE_STAGE_EARLY_FRAGMENT_TESTS_BIT = 0x00000100,
    VK_PIPELINE_STAGE_LATE_FRAGMENT_TESTS_BIT = 0x00000200,
    VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT = 0x00000400,
    VK_PIPELINE_STAGE_COMPUTE_SHADER_BIT = 0x00000800,
    VK_PIPELINE_STAGE_TRANSFER_BIT = 0x00001000,
    VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT = 0x00002000,
    VK_PIPELINE_STAGE_HOST_BIT = 0x00004000,
    VK_PIPELINE_STAGE_ALL_GRAPHICS_BIT = 0x00008000,
    VK_PIPELINE_STAGE_ALL_COMMANDS_BIT = 0x00010000,
    VK_PIPELINE_STAGE_TRANSFORM_FEEDBACK_BIT_EXT = 0x01000000,
    VK_PIPELINE_STAGE_CONDITIONAL_RENDERING_BIT_EXT = 0x00040000,
    VK_PIPELINE_STAGE_RAY_TRACING_SHADER_BIT_KHR = 0x00200000,
    VK_PIPELINE_STAGE_ACCELERATION_STRUCTURE_BUILD_BIT_KHR = 0x02000000,
    VK_PIPELINE_STAGE_SHADING_RATE_IMAGE_BIT_NV = 0x00400000,
    VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV = 0x00080000,
    VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV = 0x00100000,
    VK_PIPELINE_STAGE_FRAGMENT_DENSITY_PROCESS_BIT_EXT = 0x00800000,
    VK_PIPELINE_STAGE_COMMAND_PREPROCESS_BIT_NV = 0x00200000,
    VK_PIPELINE_STAGE_RAY_TRACING_SHADER_BIT_NV =
        VK_PIPELINE_STAGE_RAY_TRACING_SHADER_BIT_KHR,
    VK_PIPELINE_STAGE_ACCELERATION_STRUCTURE_BUILD_BIT_NV =
        VK_PIPELINE_STAGE_ACCELERATION_STRUCTURE_BUILD_BIT_KHR,
} VkPipelineStageFlagBits;
```

- **VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT** specifies the stage of the pipeline where any commands are initially received by the queue.
- **VK_PIPELINE_STAGE_DRAW_INDIRECT_BIT** specifies the stage of the pipeline where Draw/DispatchIndirect data structures are consumed. This stage also includes reading commands written by `vkCmdExecuteGeneratedCommandsNV`.
- **VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV** specifies the task shader stage.
- **VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV** specifies the mesh shader stage.
• **VK_PIPELINE_STAGE_VERTEX_INPUT_BIT** specifies the stage of the pipeline where vertex and index buffers are consumed.

• **VK_PIPELINE_STAGE_VERTEX_SHADER_BIT** specifies the vertex shader stage.

• **VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT** specifies the tessellation control shader stage.

• **VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT** specifies the tessellation evaluation shader stage.

• **VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT** specifies the geometry shader stage.

• **VK_PIPELINE_STAGE_FRAGMENT_SHADER_BIT** specifies the fragment shader stage.

• **VK_PIPELINE_STAGE_EARLY_FRAGMENT_TESTS_BIT** specifies the stage of the pipeline where early fragment tests (depth and stencil tests before fragment shading) are performed. This stage also includes subpass load operations for framebuffer attachments with a depth/stencil format.

• **VK_PIPELINE_STAGE_LATE_FRAGMENT_TESTS_BIT** specifies the stage of the pipeline where late fragment tests (depth and stencil tests after fragment shading) are performed. This stage also includes subpass store operations for framebuffer attachments with a depth/stencil format.

• **VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT** specifies the stage of the pipeline after blending where the final color values are output from the pipeline. This stage also includes subpass load and store operations and multisample resolve operations for framebuffer attachments with a color or depth/stencil format.

• **VK_PIPELINE_STAGE_COMPUTE_SHADER_BIT** specifies the execution of a compute shader.

• **VK_PIPELINE_STAGE_TRANSFER_BIT** specifies the following commands:
  1. All copy commands, including `vkCmdCopyQueryPoolResults`
  2. `vkCmdBlitImage`
  3. `vkCmdResolveImage`
  4. All clear commands, with the exception of `vkCmdClearAttachments`

• **VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT** specifies the final stage in the pipeline where operations generated by all commands complete execution.

• **VK_PIPELINE_STAGE_HOST_BIT** specifies a pseudo-stage indicating execution on the host of reads/writes of device memory. This stage is not invoked by any commands recorded in a command buffer.

• **VK_PIPELINE_STAGE_RAY_TRACING_SHADER_BIT_KHR** specifies the execution of the ray tracing shader stages.

• **VK_PIPELINE_STAGE_ACCELERATION_STRUCTURE_BUILD_BIT_KHR** specifies the execution of `vkCmdBuildAccelerationStructureKHR`, `vkCmdCopyAccelerationStructureKHR`, and `vkCmdWriteAccelerationStructuresPropertiesKHR`.

• **VK_PIPELINE_STAGE_ALL_GRAPHICS_BIT** specifies the execution of all graphics pipeline stages, and is equivalent to the logical OR of:
  1. **VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT**
  2. **VK_PIPELINE_STAGE_DRAW_INDIRECT_BIT**
• \texttt{VK\_PIPELINE\_STAGE\_ALL\_COMMANDS\_BIT} is equivalent to the logical OR of every other pipeline stage flag that is supported on the queue it is used with.

• \texttt{VK\_PIPELINE\_STAGE\_CONDITIONAL\_RENDERING\_BIT\_EXT} specifies the stage of the pipeline where the predicate of conditional rendering is consumed.

• \texttt{VK\_PIPELINE\_STAGE\_TRANSFORM\_FEEDBACK\_BIT\_EXT} specifies the stage of the pipeline where vertex attribute output values are written to the transform feedback buffers.

• \texttt{VK\_PIPELINE\_STAGE\_COMMAND\_PREPROCESS\_BIT\_NV} specifies the stage of the pipeline where device-side preprocessing for generated commands via \texttt{vkCmdPreprocessGeneratedCommandsNV} is handled.

• \texttt{VK\_PIPELINE\_STAGE\_SHADING\_RATE\_IMAGE\_BIT\_NV} specifies the stage of the pipeline where the shading rate image is read to determine the shading rate for portions of a rasterized primitive.

• \texttt{VK\_PIPELINE\_STAGE\_FRAGMENT\_DENSITY\_PROCESS\_BIT\_EXT} specifies the stage of the pipeline where the fragment density map is read to generate the fragment areas.
**Note**
An execution dependency with only `VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT` in the destination stage mask will only prevent that stage from executing in subsequently submitted commands. As this stage does not perform any actual execution, this is not observable - in effect, it does not delay processing of subsequent commands. Similarly an execution dependency with only `VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT` in the source stage mask will effectively not wait for any prior commands to complete.

When defining a memory dependency, using only `VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT` or `VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT` would never make any accesses available and/or visible because these stages do not access memory.

`VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT` and `VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT` are useful for accomplishing layout transitions and queue ownership operations when the required execution dependency is satisfied by other means - for example, semaphore operations between queues.

```c
typedef VkFlags VkPipelineStageFlags;
```

`VkPipelineStageFlags` is a bitmask type for setting a mask of zero or more `VkPipelineStageFlagBits`.

If a synchronization command includes a source stage mask, its first **synchronization scope** only includes execution of the pipeline stages specified in that mask, and its first **access scope** only includes memory access performed by pipeline stages specified in that mask. If a synchronization command includes a destination stage mask, its second **synchronization scope** only includes execution of the pipeline stages specified in that mask, and its second **access scope** only includes memory access performed by pipeline stages specified in that mask.

**Note**
Including a particular pipeline stage in the first **synchronization scope** of a command implicitly includes **logically earlier** pipeline stages in the synchronization scope. Similarly, the second **synchronization scope** includes **logically later** pipeline stages.

However, note that **access scopes** are not affected in this way - only the precise stages specified are considered part of each access scope.

Certain pipeline stages are only available on queues that support a particular set of operations. The following table lists, for each pipeline stage flag, which queue capability flag must be supported by the queue. When multiple flags are enumerated in the second column of the table, it means that the pipeline stage is supported on the queue if it supports any of the listed capability flags. For further details on queue capabilities see Physical Device Enumeration and Queues.

</tbody>
</table>

Pipeline stages that execute as a result of a command logically complete execution in a specific order, such that completion of a logically later pipeline stage must not happen-before completion of a logically earlier stage. This means that including any stage in the source stage mask for a particular synchronization command also implies that any logically earlier stages are included in A, for that command.

Similarly, initiation of a logically earlier pipeline stage must not happen-after initiation of a logically later pipeline stage. Including any given stage in the destination stage mask for a particular synchronization command also implies that any logically later stages are included in B, for that command.

154 | Chapter 6. Synchronization and Cache Control
Note
Implementations may not support synchronization at every pipeline stage for every synchronization operation. If a pipeline stage that an implementation does not support synchronization for appears in a source stage mask, it may substitute any logically later stage in its place for the first synchronization scope. If a pipeline stage that an implementation does not support synchronization for appears in a destination stage mask, it may substitute any logically earlier stage in its place for the second synchronization scope.

For example, if an implementation is unable to signal an event immediately after vertex shader execution is complete, it may instead signal the event after color attachment output has completed.

If an implementation makes such a substitution, it must not affect the semantics of execution or memory dependencies or image and buffer memory barriers.

The order and set of pipeline stages executed by a given command is determined by the command's pipeline type, as described below:

For the graphics primitive shading pipeline, the following stages occur in this order:

- VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT
- VK_PIPELINE_STAGE_DRAW_INDIRECT_BIT
- VK_PIPELINE_STAGE_VERTEX_INPUT_BIT
- VK_PIPELINE_STAGE_VERTEX_SHADER_BIT
- VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT
- VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT
- VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT
- VK_PIPELINE_STAGE_TRANSFORM_FEEDBACK_BIT_EXT
- VK_PIPELINE_STAGE_SHADING_RATE_IMAGE_BIT_NV
- VK_PIPELINE_STAGE_EARLY_FRAGMENT_TESTS_BIT
- VK_PIPELINE_STAGE_FRAGMENT_SHADER_BIT
- VK_PIPELINE_STAGE_LATE_FRAGMENT_TESTS_BIT
- VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT
- VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT

For the graphics mesh shading pipeline, the following stages occur in this order:

- VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT
- VK_PIPELINE_STAGE_DRAW_INDIRECT_BIT
- VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV
For graphics pipeline commands executing in a render pass with a fragment density map attachment, the following pipeline stage where the fragment density map read happens has no particular order relative to the other stages, except that it is logically earlier than `VK_PIPELINE_STAGE_EARLY_FRAGMENT_TESTS_BIT`:

- `VK_PIPELINE_STAGE_FRAGMENT_DENSITY_PROCESS_BIT_EXT`
- `VK_PIPELINE_STAGE_EARLY_FRAGMENT_TESTS_BIT`

For the compute pipeline, the following stages occur in this order:

- `VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT`
- `VK_PIPELINE_STAGE_DRAW_INDIRECT_BIT`
- `VK_PIPELINE_STAGE_COMPUTE_SHADER_BIT`
- `VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT`

The conditional rendering stage is formally part of both the graphics, and the compute pipeline. The pipeline stage where the predicate read happens has unspecified order relative to other stages of these pipelines:

- `VK_PIPELINE_STAGE_CONDITIONAL_RENDERING_BIT_EXT`

For the transfer pipeline, the following stages occur in this order:

- `VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT`
- `VK_PIPELINE_STAGE_TRANSFER_BIT`
- `VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT`

For host operations, only one pipeline stage occurs, so no order is guaranteed:

- `VK_PIPELINE_STAGE_HOST_BIT`

For the command preprocessing pipeline, the following stages occur in this order:

- `VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT`
- `VK_PIPELINE_STAGE_COMMAND_PREPROCESS_BIT_NV`
- `VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT`
For the ray tracing shader pipeline, only one pipeline stage occurs, so no order is guaranteed:

- VK_PIPELINE_STAGE_RAY_TRACING_SHADER_BIT_KHR

For ray tracing acceleration structure operations, only one pipeline stage occurs, so no order is guaranteed:

- VK_PIPELINE_STAGE_ACCELERATION_STRUCTURE_BUILD_BIT_KHR

### 6.1.3. Access Types

Memory in Vulkan can be accessed from within shader invocations and via some fixed-function stages of the pipeline. The access type is a function of the descriptor type used, or how a fixed-function stage accesses memory. Each access type corresponds to a bit flag in VkAccessFlagBits.

Some synchronization commands take sets of access types as parameters to define the access scopes of a memory dependency. If a synchronization command includes a source access mask, its first access scope only includes accesses via the access types specified in that mask. Similarly, if a synchronization command includes a destination access mask, its second access scope only includes accesses via the access types specified in that mask.

Access types that can be set in an access mask include:
typedef enum VkAccessFlagBits {
    VK_ACCESS_INDIRECT_COMMAND_READ_BIT = 0x00000001,
    VK_ACCESS_INDEX_READ_BIT = 0x00000002,
    VK_ACCESS_VERTEX_ATTRIBUTE_READ_BIT = 0x00000004,
    VK_ACCESS_UNIFORM_READ_BIT = 0x00000008,
    VK_ACCESS_INPUT_ATTACHMENT_READ_BIT = 0x00000010,
    VK_ACCESS_SHADER_READ_BIT = 0x00000020,
    VK_ACCESS_SHADER_WRITE_BIT = 0x00000040,
    VK_ACCESS_COLOR_ATTACHMENT_READ_BIT = 0x00000080,
    VK_ACCESS_COLOR_ATTACHMENT_WRITE_BIT = 0x00000100,
    VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_READ_BIT = 0x00000200,
    VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_WRITE_BIT = 0x00000400,
    VK_ACCESS_TRANSFER_READ_BIT = 0x00000800,
    VK_ACCESS_TRANSFER_WRITE_BIT = 0x00001000,
    VK_ACCESS_HOST_READ_BIT = 0x00002000,
    VK_ACCESS_HOST_WRITE_BIT = 0x00004000,
    VK_ACCESS_MEMORY_READ_BIT = 0x00008000,
    VK_ACCESS_MEMORY_WRITE_BIT = 0x00010000,
    VK_ACCESS_TRANSFORM_FEEDBACK_WRITE_BIT_EXT = 0x02000000,
    VK_ACCESS_TRANSFORM_FEEDBACK_COUNTER_READ_BIT_EXT = 0x04000000,
    VK_ACCESS_TRANSFORM_FEEDBACK_COUNTER_WRITE_BIT_EXT = 0x08000000,
    VK_ACCESS_CONDITIONAL_RENDERING_READ_BIT_EXT = 0x00100000,
    VK_ACCESS_COLOR_ATTACHMENT_READ_NONCOHERENT_BIT_EXT = 0x00080000,
    VK_ACCESS_ACCELERATION_STRUCTURE_READ_BIT_KHR = 0x00200000,
    VK_ACCESS_ACCELERATION_STRUCTURE_WRITE_BIT_KHR = 0x00400000,
    VK_ACCESS_SHADING_RATE_IMAGE_READ_BIT_NV = 0x00800000,
    VK_ACCESS_FRAGMENT DENSITY MAP_READ_BIT_EXT = 0x01000000,
    VK_ACCESS_COMMAND_PREPROCESS_READ_BIT_NV = 0x00020000,
    VK_ACCESS_COMMAND_PREPROCESS_WRITE_BIT_NV = 0x00040000,
    VK_ACCESS_ACCELERATION_STRUCTURE_READ_BIT_NV =
    VK_ACCESS_ACCELERATION_STRUCTUREWRITE_BIT_KHR,
    VK_ACCESS_ACCELERATION_STRUCTURE_WRITE_BIT_NV =
    VK_ACCESS_ACCELERATION_STRUCTURE_WRITE_BIT_KHR,
} VkAccessFlagBits;

- **VK_ACCESS_INDIRECT_COMMAND_READ_BIT** specifies read access to indirect command data read as part of an indirect drawing or dispatch command.

- **VK_ACCESS_INDEX_READ_BIT** specifies read access to an index buffer as part of an indexed drawing command, bound by `vkCmdBindIndexBuffer`.

- **VK_ACCESS_VERTEX_ATTRIBUTE_READ_BIT** specifies read access to a vertex buffer as part of a drawing command, bound by `vkCmdBindVertexBuffers`.

- **VK_ACCESS_UNIFORM_READ_BIT** specifies read access to a uniform buffer.

- **VK_ACCESS_INPUT_ATTACHMENT_READ_BIT** specifies read access to an input attachment within a render pass during fragment shading.

- **VK_ACCESS_SHADER_READ_BIT** specifies read access to a storage buffer, physical storage buffer, uniform texel buffer, storage texel buffer, sampled image, or storage image.
• **VK_ACCESS_SHADER_WRITE_BIT** specifies write access to a storage buffer, physical storage buffer, storage texel buffer, or storage image.

• **VK_ACCESS_COLOR_ATTACHMENT_READ_BIT** specifies read access to a color attachment, such as via blending, logic operations, or via certain subpass load operations. It does not include advanced blend operations.

• **VK_ACCESS_COLOR_ATTACHMENT_WRITE_BIT** specifies write access to a color, resolve, or depth/stencil resolve attachment during a render pass or via certain subpass load and store operations.

• **VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_READ_BIT** specifies read access to a depth/stencil attachment, via depth or stencil operations or via certain subpass load operations.

• **VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_WRITE_BIT** specifies write access to a depth/stencil attachment, via depth or stencil operations or via certain subpass load and store operations.

• **VK_ACCESS_TRANSFER_READ_BIT** specifies read access to an image or buffer in a copy operation.

• **VK_ACCESS_TRANSFER_WRITE_BIT** specifies write access to an image or buffer in a clear or copy operation.

• **VK_ACCESS_HOST_READ_BIT** specifies read access by a host operation. Accesses of this type are not performed through a resource, but directly on memory.

• **VK_ACCESS_HOST_WRITE_BIT** specifies write access by a host operation. Accesses of this type are not performed through a resource, but directly on memory.

• **VK_ACCESS_MEMORY_READ_BIT** specifies all read accesses. It is always valid in any access mask, and is treated as equivalent to setting all READ access flags that are valid where it is used.

• **VK_ACCESS_MEMORY_WRITE_BIT** specifies all write accesses. It is always valid in any access mask, and is treated as equivalent to setting all WRITE access flags that are valid where it is used.

• **VK_ACCESS_CONDITIONAL_RENDERING_READ_BIT_EXT** specifies read access to a predicate as part of conditional rendering.

• **VK_ACCESS_TRANSFORM_FEEDBACK_WRITE_BIT_EXT** specifies write access to a transform feedback buffer made when transform feedback is active.

• **VK_ACCESS_TRANSFORM_FEEDBACK_COUNTER_READ_BIT_EXT** specifies read access to a transform feedback counter buffer which is read when **vkCmdBeginTransformFeedbackEXT** executes.

• **VK_ACCESS_TRANSFORM_FEEDBACK_COUNTER_WRITE_BIT_EXT** specifies write access to a transform feedback counter buffer which is written when **vkCmdEndTransformFeedbackEXT** executes.

• **VK_ACCESS_COMMAND_PREPROCESS_READ_BIT_NV** specifies reads from **VkBuffer** inputs to **vkCmdPreprocessGeneratedCommandsNV**.

• **VK_ACCESS_COMMAND_PREPROCESS_WRITE_BIT_NV** specifies writes to the **VkBuffer** preprocess outputs in **vkCmdPreprocessGeneratedCommandsNV**.

• **VK_ACCESS_COLOR_ATTACHMENT_READ_NONCOHERENT_BIT_EXT** is similar to **VK_ACCESS_COLOR_ATTACHMENT_READ_BIT**, but also includes advanced blend operations.

• **VK_ACCESS_SHADING_RATE_IMAGE_READ_BIT_NV** specifies read access to a shading rate image as part of a drawing command, as bound by **vkCmdBindShadingRateImageNV**.

• **VK_ACCESS_ACCELERATION_STRUCTURE_READ_BIT_KHR** specifies read access to an acceleration structure as part of a trace or build command.
• **VK_ACCESS_ACCELERATION_STRUCTURE_WRITE_BIT_KHR** specifies write access to an acceleration structure as part of a build command.

• **VK_ACCESS_FRAGMENT_DENSITY_MAP_READ_BIT_EXT** specifies read access to a fragment density map attachment during dynamic fragment density map operations.

Certain access types are only performed by a subset of pipeline stages. Any synchronization command that takes both stage masks and access masks uses both to define the access scopes - only the specified access types performed by the specified stages are included in the access scope. An application **must** not specify an access flag in a synchronization command if it does not include a pipeline stage in the corresponding stage mask that is able to perform accesses of that type. The following table lists, for each access flag, which pipeline stages *can* perform that type of access.

**Table 4. Supported access types**

</tbody>
</table>

If a memory object does not have the **VK_MEMORY_PROPERTY_HOST_COHERENT_BIT** property, then **vkFlushMappedMemoryRanges** must be called in order to guarantee that writes to the memory object from the host are made available to the host domain, where they can be further made available to the device domain via a domain operation. Similarly, **vkInvalidateMappedMemoryRanges** must be called to guarantee that writes which are available to the host domain are made visible to host operations.

If the memory object does have the **VK_MEMORY_PROPERTY_HOST_COHERENT_BIT** property flag, writes to the memory object from the host are automatically made available to the host domain. Similarly,
writes made available to the host domain are automatically made visible to the host.

Note
The `vkQueueSubmit` command automatically performs a domain operation from host to device for all writes performed before the command executes, so in most cases an explicit memory barrier is not needed for this case. In the few circumstances where a submit does not occur between the host write and the device read access, writes can be made available by using an explicit memory barrier.

typedef VkFlags VkAccessFlags;

`VkAccessFlags` is a bitmask type for setting a mask of zero or more `VkAccessFlagBits`.

### 6.1.4. Framebuffer Region Dependencies

Pipeline stages that operate on, or with respect to, the framebuffer are collectively the framebuffer-space pipeline stages. These stages are:

- `VK_PIPELINE_STAGE_FRAGMENT_SHADER_BIT`
- `VK_PIPELINE_STAGE_EARLY_FRAGMENT_TESTS_BIT`
- `VK_PIPELINE_STAGE_LATE_FRAGMENT_TESTS_BIT`
- `VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT`

For these pipeline stages, an execution or memory dependency from the first set of operations to the second set can either be a single framebuffer-global dependency, or split into multiple framebuffer-local dependencies. A dependency with non-framebuffer-space pipeline stages is neither framebuffer-global nor framebuffer-local.

A framebuffer region is a subset of the entire framebuffer, and can either be:

- A sample region, which is set of sample (x, y, layer, sample) coordinates that is a subset of the entire framebuffer, or

- A fragment region, which is a set of fragment (x, y, layer) coordinates that is a subset of the entire framebuffer.

Both synchronization scopes of a framebuffer-local dependency include only the operations performed within corresponding framebuffer regions (as defined below). No ordering guarantees are made between different framebuffer regions for a framebuffer-local dependency.

Both synchronization scopes of a framebuffer-global dependency include operations on all framebuffer-regions.

If the first synchronization scope includes operations on pixels/fragments with N samples and the second synchronization scope includes operations on pixels/fragments with M samples, where N does not equal M, then a framebuffer region containing all samples at a given (x, y, layer) coordinate in the first synchronization scope corresponds to a region containing all samples at the
same coordinate in the second synchronization scope. In other words, the framebuffer region is a fragment region and it is a pixel granularity dependency. If N equals M, and if the `VkSubpassDescription::flags` does not specify the `VK_SUBPASS_DESCRIPTION_FRAGMENT_REGION_BIT_QCOM` flag, then a framebuffer region containing a single (x, y, layer, sample) coordinate in the first synchronization scope corresponds to a region containing the same sample at the same coordinate in the second synchronization scope. In other words, the framebuffer region is a sample region and it is a sample granularity dependency.

**Note**
Since fragment invocations are not specified to run in any particular groupings, the size of a framebuffer region is implementation-dependent, not known to the application, and **must** be assumed to be no larger than specified above.

**Note**
Practically, the pixel vs sample granularity dependency means that if an input attachment has a different number of samples than the pipeline's `rasterizationSamples`, then a fragment **can** access any sample in the input attachment's pixel even if it only uses framebuffer-local dependencies. If the input attachment has the same number of samples, then the fragment **can** only access the covered samples in its input `SampleMask` (i.e. the fragment operations happen-after a framebuffer-local dependency for each sample the fragment covers). To access samples that are not covered, either the `VkSubpassDescription::flags VK_SUBPASS_DESCRIPTION_FRAGMENT_REGION_BIT_QCOM` flag is required, or a framebuffer-global dependency is required.

If a synchronization command includes a `dependencyFlags` parameter, and specifies the `VK_DEPENDENCY_BY_REGION_BIT` flag, then it defines framebuffer-local dependencies for the framebuffer-space pipeline stages in that synchronization command, for all framebuffer regions. If no `dependencyFlags` parameter is included, or the `VK_DEPENDENCY_BY_REGION_BIT` flag is not specified, then a framebuffer-global dependency is specified for those stages. The `VK_DEPENDENCY_BY_REGION_BIT` flag does not affect the dependencies between non-framebuffer-space pipeline stages, nor does it affect the dependencies between framebuffer-space and non-framebuffer-space pipeline stages.

**Note**
Framebuffer-local dependencies are more optimal for most architectures; particularly tile-based architectures - which can keep framebuffer-regions entirely in on-chip registers and thus avoid external bandwidth across such a dependency. Including a framebuffer-global dependency in your rendering will usually force all implementations to flush data to memory, or to a higher level cache, breaking any potential locality optimizations.

### 6.1.5. View-Local Dependencies

In a render pass instance that has `multiview` enabled, dependencies **can** be either view-local or view-global.
A view-local dependency only includes operations from a single source view from the source subpass in the first synchronization scope, and only includes operations from a single destination view from the destination subpass in the second synchronization scope. A view-global dependency includes all views in the view mask of the source and destination subpasses in the corresponding synchronization scopes.

If a synchronization command includes a dependencyFlags parameter and specifies the VK_DEPENDENCY_VIEW_LOCAL_BIT flag, then it defines view-local dependencies for that synchronization command, for all views. If no dependencyFlags parameter is included or the VK_DEPENDENCY_VIEW_LOCAL_BIT flag is not specified, then a view-global dependency is specified.

### 6.1.6. Device-Local Dependencies

Dependencies can be either device-local or non-device-local. A device-local dependency acts as multiple separate dependencies, one for each physical device that executes the synchronization command, where each dependency only includes operations from that physical device in both synchronization scopes. A non-device-local dependency is a single dependency where both synchronization scopes include operations from all physical devices that participate in the synchronization command. For subpass dependencies, all physical devices in the VkDeviceGroupRenderPassBeginInfo::deviceMask participate in the dependency, and for pipeline barriers all physical devices that are set in the command buffer's current device mask participate in the dependency.

If a synchronization command includes a dependencyFlags parameter and specifies the VK_DEPENDENCY_DEVICE_GROUP_BIT flag, then it defines a non-device-local dependency for that synchronization command. If no dependencyFlags parameter is included or the VK_DEPENDENCY_DEVICE_GROUP_BIT flag is not specified, then it defines device-local dependencies for that synchronization command, for all participating physical devices.

Semaphore and event dependencies are device-local and only execute on the one physical device that performs the dependency.

### 6.2. Implicit Synchronization Guarantees

A small number of implicit ordering guarantees are provided by Vulkan, ensuring that the order in which commands are submitted is meaningful, and avoiding unnecessary complexity in common operations.

Submission order is a fundamental ordering in Vulkan, giving meaning to the order in which action and synchronization commands are recorded and submitted to a single queue. Explicit and implicit ordering guarantees between commands in Vulkan all work on the premise that this ordering is meaningful. This order does not itself define any execution or memory dependencies; synchronization commands and other orderings within the API use this ordering to define their scopes.

Submission order for any given set of commands is based on the order in which they were recorded to command buffers and then submitted. This order is determined as follows:

1. The initial order is determined by the order in which vkQueueSubmit commands are executed
on the host, for a single queue, from first to last.

2. The order in which VkSubmitInfo structures are specified in the pSubmits parameter of vkQueueSubmit, from lowest index to highest.

3. The order in which command buffers are specified in the pCommandBuffers member of VkSubmitInfo, from lowest index to highest.

4. The order in which commands were recorded to a command buffer on the host, from first to last:
   - For commands recorded outside a render pass, this includes all other commands recorded outside a render pass, including vkCmdBeginRenderPass and vkCmdEndRenderPass commands; it does not directly include commands inside a render pass.
   - For commands recorded inside a render pass, this includes all other commands recorded inside the same subpass, including the vkCmdBeginRenderPass and vkCmdEndRenderPass commands that delimit the same render pass instance; it does not include commands recorded to other subpasses.

**Action and synchronization commands** recorded to a command buffer execute the VK_PIPELINE_STAGE_TOP_OF_PIPE_BIT pipeline stage in submission order - forming an implicit execution dependency between this stage in each command.

**State commands** do not execute any operations on the device, instead they set the state of the command buffer when they execute on the host, in the order that they are recorded. **Action commands** consume the current state of the command buffer when they are recorded, and will execute state changes on the device as required to match the recorded state.

**Query commands**, the order of primitives passing through the graphics pipeline and image layout transitions as part of an image memory barrier provide additional guarantees based on submission order.

Execution of **pipeline stages** within a given command also has a loose ordering, dependent only on a single command.

**Signal operation order** is a fundamental ordering in Vulkan, giving meaning to the order in which semaphore and fence signal operations occur when submitted to a single queue. The signal operation order for queue operations is determined as follows:

1. The initial order is determined by the order in which vkQueueSubmit commands are executed on the host, for a single queue, from first to last.
2. The order in which VkSubmitInfo structures are specified in the pSubmits parameter of vkQueueSubmit, from lowest index to highest.
3. The fence signal operation defined by the fence parameter of a vkQueueSubmit or vkQueueBindSparse command is ordered after all semaphore signal operations defined by that command.

Semaphore signal operations defined by a single VkSubmitInfo or VkBindSparseInfo structure are unordered with respect to other semaphore signal operations defined within the same VkSubmitInfo or VkBindSparseInfo structure.
The `vkSignalSemaphore` command does not execute on a queue but instead performs the signal operation from the host. The semaphore signal operation defined by executing a `vkSignalSemaphore` command happens-after the `vkSignalSemaphore` command is invoked and happens-before the command returns.

**Note**

When signaling timeline semaphores, it is the responsibility of the application to ensure that they are ordered such that the semaphore value is strictly increasing. Because the first synchronization scope for a semaphore signal operation contains all semaphore signal operations which occur earlier in submission order, all semaphore signal operations contained in any given batch are guaranteed to happen-after all semaphore signal operations contained in any previous batches. However, no ordering guarantee is provided between the semaphore signal operations defined within a single batch. This, combined with the requirement that timeline semaphore values strictly increase, means that it is invalid to signal the same timeline semaphore twice within a single batch.

If an application wishes to ensure that some semaphore signal operation happens-after some other semaphore signal operation, it can submit a separate batch containing only semaphore signal operations, which will happen-after the semaphore signal operations in any earlier batches.

When signaling a semaphore from the host, the only ordering guarantee is that the signal operation happens-after when `vkSignalSemaphore` is called and happens-before it returns. Therefore, it is invalid to call `vkSignalSemaphore` while there are any outstanding signal operations on that semaphore from any queue submissions unless those queue submissions have some dependency which ensures that they happen-after the host signal operation. One example of this would be if the pending signal operation is, itself, waiting on the same semaphore at a lower value and the call to `vkSignalSemaphore` signals that lower value. Furthermore, if there are two or more processes or threads signaling the same timeline semaphore from the host, the application must ensure that the `vkSignalSemaphore` with the lower semaphore value returns before `vkSignalSemaphore` is called with the higher value.

### 6.3. Fences

Fences are a synchronization primitive that can be used to insert a dependency from a queue to the host. Fences have two states - signaled and unsignaled. A fence can be signaled as part of the execution of a queue submission command. Fences can be unsignaled on the host with `vkResetFences`. Fences can be waited on by the host with the `vkWaitForFences` command, and the current state can be queried with `vkGetFenceStatus`.

As with most objects in Vulkan, fences are an interface to internal data which is typically opaque to applications. This internal data is referred to as a fence’s **payload**.

However, in order to enable communication with agents outside of the current device, it is necessary to be able to export that payload to a commonly understood format, and subsequently import from that format as well.
The internal data of a fence may include a reference to any resources and pending work associated with signal or unsignal operations performed on that fence object. Mechanisms to import and export that internal data to and from fences are provided below. These mechanisms indirectly enable applications to share fence state between two or more fences and other synchronization primitives across process and API boundaries.

Fences are represented by VkFence handles:

```cpp
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkFence)
```

To create a fence, call:

```cpp
VkResult vkCreateFence(
    VkDevice device,
    const VkFenceCreateInfo* pCreateInfo,
    const VkAllocationCallbacks* pAllocator,
    VkFence* pFence);
```

- `device` is the logical device that creates the fence.
- `pCreateInfo` is a pointer to a `VkFenceCreateInfo` structure containing information about how the fence is to be created.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
- `pFence` is a pointer to a handle in which the resulting fence object is returned.

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pCreateInfo` must be a valid pointer to a valid `VkFenceCreateInfo` structure
- If `pAllocator` is not NULL, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- `pFence` must be a valid pointer to a `VkFence` handle

### Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

The `VkFenceCreateInfo` structure is defined as:
typedef struct VkFenceCreateInfo {
    VkStructureType       sType;
    const void*           pNext;
    VkFenceCreateFlags    flags;
} VkFenceCreateInfo;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `flags` is a bitmask of `VkFenceCreateFlagBits` specifying the initial state and behavior of the fence.

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_FENCE_CREATE_INFO`
- Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkExportFenceCreateInfo` or `VkExportFenceWin32HandleInfoKHR`
- The `sType` value of each struct in the `pNext` chain must be unique
- `flags` must be a valid combination of `VkFenceCreateFlagBits` values

typedef enum VkFenceCreateFlagBits {
    VK_FENCE_CREATE_SIGNALED_BIT = 0x00000001,
} VkFenceCreateFlagBits;

- `VK_FENCE_CREATE_SIGNALED_BIT` specifies that the fence object is created in the signaled state. Otherwise, it is created in the unsignaled state.

typedef VkFlags VkFenceCreateFlags;

`VkFenceCreateFlags` is a bitmask type for setting a mask of zero or more `VkFenceCreateFlagBits`.

To create a fence whose payload can be exported to external handles, add a `VkExportFenceCreateInfo` structure to the `pNext` chain of the `VkFenceCreateInfo` structure. The `VkExportFenceCreateInfo` structure is defined as:

typedef struct VkExportFenceCreateInfo {
    VkStructureType                   sType;
    const void*                       pNext;
    VkExternalFenceHandleTypeFlags    handleTypes;
} VkExportFenceCreateInfo;

or the equivalent
typedef VkExportFenceCreateInfo VkExportFenceCreateInfoKHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **handleTypes** is a bitmask of VkExternalFenceHandleTypeFlagBits specifying one or more fence handle types the application can export from the resulting fence. The application can request multiple handle types for the same fence.

### Valid Usage

- The bits in **handleTypes** must be supported and compatible, as reported by VkExternalFenceProperties

### Valid Usage (Implicit)

- **sType** must be VK_STRUCTURE_TYPE_EXPORT_FENCE_CREATE_INFO
- **handleTypes** must be a valid combination of VkExternalFenceHandleTypeFlagBits values

To specify additional attributes of NT handles exported from a fence, add a VkExportFenceWin32HandleInfoKHR structure to the **pNext** chain of the VkFenceCreateInfo structure. The VkExportFenceWin32HandleInfoKHR structure is defined as:

```c
typedef struct VkExportFenceWin32HandleInfoKHR {
    VkStructureType               sType;
    const void*                   pNext;
    const SECURITY_ATTRIBUTES*    pAttributes;
    DWORD                         dwAccess;
    LPCWSTR                       name;
} VkExportFenceWin32HandleInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **pAttributes** is a pointer to a Windows SECURITY_ATTRIBUTES structure specifying security attributes of the handle.
- **dwAccess** is a DWORD specifying access rights of the handle.
- **name** is a null-terminated UTF-16 string to associate with the underlying synchronization primitive referenced by NT handles exported from the created fence.

If VkExportFenceCreateInfo is not present in the same **pNext** chain, this structure is ignored.

If VkExportFenceCreateInfo is present in the **pNext** chain of VkFenceCreateInfo with a Windows handleType, but either VkExportFenceWin32HandleInfoKHR is not present in the **pNext** chain, or if it is
but \texttt{pAttributes} is set to \texttt{NULL}, default security descriptor values will be used, and child processes created by the application will not inherit the handle, as described in the MSDN documentation for “Synchronization Object Security and Access Rights”. Further, if the structure is not present, the access rights will be

\texttt{DXGI\_SHARED\_RESOURCE\_READ | DXGI\_SHARED\_RESOURCE\_WRITE}

for handles of the following types:

\texttt{VK\_EXTERNAL\_FENCE\_HANDLE\_TYPE\_OPAQUE\_WIN32\_BIT}

1

\url{https://docs.microsoft.com/en-us/windows/win32/sync/synchronization-object-security-and-access-rights}

### Valid Usage

- If \texttt{VkExportFenceCreateInfo::handleTypes} does not include \texttt{VK\_EXTERNAL\_FENCE\_HANDLE\_TYPE\_OPAQUE\_WIN32\_BIT}, a \texttt{VkExportFenceWin32HandleInfoKHR} structure \textbf{must} not be included in the \texttt{pNext} chain of \texttt{VkFenceCreateInfo}

### Valid Usage (Implicit)

- \texttt{sType} \textbf{must} be \texttt{VK\_STRUCTURE\_TYPE\_EXPORT\_FENCE\_WIN32\_HANDLE\_INFO\_KHR}
- If \texttt{pAttributes} is not \texttt{NULL}, \texttt{pAttributes} \textbf{must} be a valid pointer to a valid \texttt{SECURITY\_ATTRIBUTES} value

To export a Windows handle representing the state of a fence, call:

\begin{verbatim}
VkResult vkGetFenceWin32HandleKHR(
    VkDevice                            device,
    const VkFenceGetWin32HandleInfoKHR* pGetWin32HandleInfo,
    HANDLE*                            pHandle);
\end{verbatim}

- \texttt{device} is the logical device that created the fence being exported.
- \texttt{pGetWin32HandleInfo} is a pointer to a \texttt{VkFenceGetWin32HandleInfoKHR} structure containing parameters of the export operation.
- \texttt{pHandle} will return the Windows handle representing the fence state.

For handle types defined as NT handles, the handles returned by \texttt{vkGetFenceWin32HandleKHR} are owned by the application. To avoid leaking resources, the application \textbf{must} release ownership of them using the \texttt{CloseHandle} system call when they are no longer needed.

Exporting a Windows handle from a fence \textbf{may} have side effects depending on the transference of the specified handle type, as described in \textit{Importing Fence Payloads}.
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pGetWin32HandleInfo** must be a valid pointer to a valid `VkFenceGetWin32HandleInfoKHR` structure
- **pHandle** must be a valid pointer to a `HANDLE` value

Return Codes

**Success**
- `VK_SUCCESS`

**Failure**
- `VK_ERROR_TOO_MANY_OBJECTS`
- `VK_ERROR_OUT_OF_HOST_MEMORY`

The `VkFenceGetWin32HandleInfoKHR` structure is defined as:

```c
typedef struct VkFenceGetWin32HandleInfoKHR {
    VkStructureType                      sType;
    const void*                          pNext;
    VkFence                              fence;
    VkExternalFenceHandleTypeFlagBits    handleType;
} VkFenceGetWin32HandleInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **fence** is the fence from which state will be exported.
- **handleType** is the type of handle requested.

The properties of the handle returned depend on the value of `handleType`. See `VkExternalFenceHandleTypeFlagBits` for a description of the properties of the defined external fence handle types.
Valid Usage

- `handleType must` have been included in `VkExportFenceCreateInfo::handleTypes` when the fence’s current payload was created.
- If `handleType` is defined as an NT handle, `vkGetFenceWin32HandleKHR must` be called no more than once for each valid unique combination of fence and `handleType`.
- `fence must` not currently have its payload replaced by an imported payload as described below in Importing Fence Payloads unless that imported payload’s handle type was included in `VkExternalFenceProperties::exportFromImportedHandleTypes` for `handleType`.
- If `handleType` refers to a handle type with copy payload transference semantics, `fence must` be signaled, or have an associated fence signal operation pending execution.
- `handleType must` be defined as an NT handle or a global share handle.

Valid Usage (Implicit)

- `sType must` be `VK_STRUCTURE_TYPE_FENCE_GET_WIN32_HANDLE_INFO_KHR`.
- `pNext must` be `NULL`.
- `fence must` be a valid `VkFence` handle.
- `handleType must` be a valid `VkExternalFenceHandleTypeFlagBits` value.

To export a POSIX file descriptor representing the payload of a fence, call:

```c
VkResult vkGetFenceFdKHR(
    VkDevice device,                  
    const VkFenceGetFdInfoKHR* pGetFdInfo,  
    int* pFd);
```

- `device` is the logical device that created the fence being exported.
- `pGetFdInfo` is a pointer to a `VkFenceGetFdInfoKHR` structure containing parameters of the export operation.
- `pFd` will return the file descriptor representing the fence payload.

Each call to `vkGetFenceFdKHR` must create a new file descriptor and transfer ownership of it to the application. To avoid leaking resources, the application must release ownership of the file descriptor when it is no longer needed.

**Note**

Ownership can be released in many ways. For example, the application can call `close()` on the file descriptor, or transfer ownership back to Vulkan by using the file descriptor to import a fence payload.
If \( p\text{GetFdInfo->handleType} \) is \( VK\_EXTERNAL\_FENCE\_HANDLE\_TYPE\_SYNC\_FD\_BIT \) and the fence is signaled at the time \( \text{vkGetFenceFdKHR} \) is called, \( p\text{Fd} \) may return the value -1 instead of a valid file descriptor.

Where supported by the operating system, the implementation must set the file descriptor to be closed automatically when an \text{execve} system call is made.

Exporting a file descriptor from a fence may have side effects depending on the transference of the specified handle type, as described in Importing Fence State.

### Valid Usage (Implicit)

- \text{device} must be a valid \text{VkDevice} handle
- \( p\text{GetFdInfo} \) must be a valid pointer to a valid \text{VkFenceGetFdInfoKHR} structure
- \( p\text{Fd} \) must be a valid pointer to an \text{int} value

### Return Codes

**Success**
- \text{VK\_SUCCESS}

**Failure**
- \text{VK\_ERROR\_TOO\_MANY\_OBJECTS}
- \text{VK\_ERROR\_OUT\_OF\_HOST\_MEMORY}

The \text{VkFenceGetFdInfoKHR} structure is defined as:

```c
typedef struct VkFenceGetFdInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkFence fence;
    VkExternalFenceHandleTypeFlagBits handleType;
} VkFenceGetFdInfoKHR;
```

- \( s\text{Type} \) is the type of this structure.
- \( p\text{Next} \) is \text{NULL} or a pointer to an extension-specific structure.
- \( \text{fence} \) is the fence from which state will be exported.
- \( \text{handleType} \) is the type of handle requested.

The properties of the file descriptor returned depend on the value of \( \text{handleType} \). See \text{VkExternalFenceHandleTypeFlagBits} for a description of the properties of the defined external fence handle types.
Valid Usage

- `handleType` must have been included in `VkExportFenceCreateInfo::handleTypes` when fence's current payload was created.

- If `handleType` refers to a handle type with copy payload transference semantics, fence must be signaled, or have an associated fence signal operation pending execution.

- fence must not currently have its payload replaced by an imported payload as described below in Importing Fence Payloads unless that imported payload's handle type was included in `VkExternalFenceProperties::exportFromImportedHandleTypes` for `handleType`.

- `handleType` must be defined as a POSIX file descriptor handle.

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_FENCE_GET_FD_INFO_KHR`.
- `pNext` must be `NULL`.
- fence must be a valid `VkFence` handle.
- `handleType` must be a valid `VkExternalFenceHandleTypeFlagBits` value.

To destroy a fence, call:

```c
void vkDestroyFence(  
    VkDevice device,  
    VkFence fence,  
    const VkAllocationCallbacks* pAllocator);
```

- `device` is the logical device that destroys the fence.
- `fence` is the handle of the fence to destroy.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

Valid Usage

- All queue submission commands that refer to fence must have completed execution.

- If `VkAllocationCallbacks` were provided when fence was created, a compatible set of callbacks must be provided here.

- If no `VkAllocationCallbacks` were provided when fence was created, `pAllocator` must be `NULL`.
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- If `fence` is not `VK_NULL_HANDLE`, `fence` must be a valid `VkFence` handle
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- If `fence` is a valid handle, it must have been created, allocated, or retrieved from `device`

Host Synchronization

- Host access to `fence` must be externally synchronized

To query the status of a fence from the host, call:

```c
VkResult vkGetFenceStatus(
    VkDevice device,              
    VkFence fence);              
```

- `device` is the logical device that owns the fence.
- `fence` is the handle of the fence to query.

Upon success, `vkGetFenceStatus` returns the status of the fence object, with the following return codes:

<table>
<thead>
<tr>
<th>Status</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>VK_SUCCESS</td>
<td>The fence specified by <code>fence</code> is signaled.</td>
</tr>
<tr>
<td>VK_NOT_READY</td>
<td>The fence specified by <code>fence</code> is unsignaled.</td>
</tr>
<tr>
<td>VK_ERROR_DEVICE_LOST</td>
<td>The device has been lost. See Lost Device.</td>
</tr>
</tbody>
</table>

If a queue submission command is pending execution, then the value returned by this command may immediately be out of date.

If the device has been lost (see Lost Device), `vkGetFenceStatus` may return any of the above status codes. If the device has been lost and `vkGetFenceStatus` is called repeatedly, it will eventually return either `VK_SUCCESS` or `VK_ERROR_DEVICE_LOST`.  

Valid Usage (Implicit)

- **device** must be a valid *VkDevice* handle
- **fence** must be a valid *VkFence* handle
- **fence** must have been created, allocated, or retrieved from *device*

Return Codes

**Success**

- VK_SUCCESS
- VK_NOT_READY

**Failure**

- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERRORDEVICE_LOST

To set the state of fences to unsignaled from the host, call:

```c
VkResult vkResetFences(
    VkDevice device,
    uint32_t fenceCount,
    const VkFence* pFences);
```

- **device** is the logical device that owns the fences.
- **fenceCount** is the number of fences to reset.
- **pFences** is a pointer to an array of fence handles to reset.

If any member of **pFences** currently has its payload imported with temporary permanence, that fence’s prior permanent payload is first restored. The remaining operations described therefore operate on the restored payload.

When **vkResetFences** is executed on the host, it defines a fence unsignal operation for each fence, which resets the fence to the unsignaled state.

If any member of **pFences** is already in the unsignaled state when **vkResetFences** is executed, then **vkResetFences** has no effect on that fence.

Valid Usage

- Each element of **pFences** must not be currently associated with any queue command that has not yet completed execution on that queue
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pFences** must be a valid pointer to an array of `fenceCount` valid `VkFence` handles
- **fenceCount** must be greater than 0
- Each element of **pFences** must have been created, allocated, or retrieved from **device**

Host Synchronization

- Host access to each member of **pFences** must be externally synchronized

Return Codes

**Success**

- **VK_SUCCESS**

**Failure**

- **VK_ERROR_OUT_OF_HOST_MEMORY**
- **VK_ERROR_OUT_OF_DEVICE_MEMORY**

When a fence is submitted to a queue as part of a queue submission command, it defines a memory dependency on the batches that were submitted as part of that command, and defines a fence signal operation which sets the fence to the signaled state.

The first synchronization scope includes every batch submitted in the same queue submission command. Fence signal operations that are defined by `vkQueueSubmit` additionally include in the first synchronization scope all commands that occur earlier in submission order. Fence signal operations that are defined by `vkQueueSubmit` or `vkQueueBindSparse` additionally include in the first synchronization scope any semaphore and fence signal operations that occur earlier in signal operation order.

The second synchronization scope only includes the fence signal operation.

The first access scope includes all memory access performed by the device.

The second access scope is empty.

To wait for one or more fences to enter the signaled state on the host, call:
VkResult vkWaitForFences(
    VkDevice device,
    uint32_t fenceCount,
    const VkFence* pFences,
    VkBool32 waitAll,
    uint64_t timeout);

- **device** is the logical device that owns the fences.
- **fenceCount** is the number of fences to wait on.
- **pFences** is a pointer to an array of **fenceCount** fence handles.
- **waitAll** is the condition that **must** be satisfied to successfully unblock the wait. If **waitAll** is `VK_TRUE`, then the condition is that all fences in **pFences** are signaled. Otherwise, the condition is that at least one fence in **pFences** is signaled.
- **timeout** is the timeout period in units of nanoseconds. **timeout** is adjusted to the closest value allowed by the implementation-dependent timeout accuracy, which **may** be substantially longer than one nanosecond, and **may** be longer than the requested period.

If the condition is satisfied when **vkWaitForFences** is called, then **vkWaitForFences** returns immediately. If the condition is not satisfied at the time **vkWaitForFences** is called, then **vkWaitForFences** will block and wait up to **timeout** nanoseconds for the condition to become satisfied.

If **timeout** is zero, then **vkWaitForFences** does not wait, but simply returns the current state of the fences. **VK_TIMEOUT** will be returned in this case if the condition is not satisfied, even though no actual wait was performed.

If the specified timeout period expires before the condition is satisfied, **vkWaitForFences** returns **VK_TIMEOUT**. If the condition is satisfied before **timeout** nanoseconds has expired, **vkWaitForFences** returns **VK_SUCCESS**.

If device loss occurs (see **Lost Device**) before the timeout has expired, **vkWaitForFences** **must** return in finite time with either **VK_SUCCESS** or **VK_ERROR_DEVICE_LOST**.

**Note**
While we guarantee that **vkWaitForFences** **must** return in finite time, no guarantees are made that it returns immediately upon device loss. However, the client can reasonably expect that the delay will be on the order of seconds and that calling **vkWaitForFences** will not result in a permanently (or seemingly permanently) dead process.
**Valid Usage (Implicit)**

- **device must** be a valid *VkDevice* handle
- **pFences must** be a valid pointer to an array of **fenceCount** valid *VkFence* handles
- **fenceCount must** be greater than 0
- Each element of **pFences** must have been created, allocated, or retrieved from **device**

**Return Codes**

**Success**

- VK_SUCCESS
- VK_TIMEOUT

**Failure**

- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_DEVICE_LOST

An execution dependency is defined by waiting for a fence to become signaled, either via **vkWaitForFences** or by polling on **vkGetFenceStatus**.

The first **synchronization scope** includes only the fence signal operation.

The second **synchronization scope** includes the host operations of **vkWaitForFences** or **vkGetFenceStatus** indicating that the fence has become signaled.

**Note**

Signaling a fence and waiting on the host does not guarantee that the results of memory accesses will be visible to the host, as the access scope of a memory dependency defined by a fence only includes device access. A **memory barrier** or other memory dependency **must** be used to guarantee this. See the description of **host access types** for more information.

**6.3.1. Alternate Methods to Signal Fences**

Besides submitting a fence to a queue as part of a **queue submission** command, a fence **may** also be signaled when a particular event occurs on a device or display.

To create a fence that will be signaled when an event occurs on a device, call:
VkResult vkRegisterDeviceEventEXT(
    VkDevice                                    device,
    const VkDeviceEventInfoEXT*                 pDeviceEventInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkFence*                                    pFence);

- **device** is a logical device on which the event **may** occur.
- **pDeviceEventInfo** is a pointer to a *VkDeviceEventInfoEXT* structure describing the event of interest to the application.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pFence** is a pointer to a handle in which the resulting fence object is returned.

**Valid Usage (Implicit)**

- **device** **must** be a valid *VkDevice* handle
- **pDeviceEventInfo** **must** be a valid pointer to a valid *VkDeviceEventInfoEXT* structure
- If **pAllocator** is not **NULL**, **pAllocator** **must** be a valid pointer to a valid *VkAllocationCallbacks* structure
- **pFence** **must** be a valid pointer to a *VkFence* handle

**Return Codes**

**Success**
- **VK_SUCCESS**

The *VkDeviceEventInfoEXT* structure is defined as:

```c
typedef struct VkDeviceEventInfoEXT {
    VkStructureType         sType;
    const void*             pNext;
    VkDeviceEventTypeEXT    deviceEvent;
} VkDeviceEventInfoEXT;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **device** is a *VkDeviceEventTypeEXT* value specifying when the fence will be signaled.
Valid Usage (Implicit)

- **sType** **must** be `VK_STRUCTURE_TYPE_DEVICE_EVENT_INFO_EXT`
- **pNext** **must** be `NULL`
- **deviceEvent** **must** be a valid `VkDeviceEventTypeEXT` value

Possible values of `VkDeviceEventTypeEXT`:

```c
typedef enum VkDeviceEventTypeEXT {
    VK_DEVICE_EVENT_TYPE_DISPLAY_HOTPLUG_EXT = 0,
} VkDeviceEventTypeEXT;
```

- `VK_DEVICE_EVENT_TYPE_DISPLAY_HOTPLUG_EXT` specifies that the fence is signaled when a display is plugged into or unplugged from the specified device. Applications **can** use this notification to determine when they need to re-enumerate the available displays on a device.

To create a fence that will be signaled when an event occurs on a `VkDisplayKHR` object, call:

```c
VkResult vkRegisterDisplayEventEXT(
    VkDevice                                    device,
    VkDisplayKHR                                display,
    constVkDisplayEventInfoEXT*                pDisplayEventInfo,
    constVkAllocationCallbacks*                pAllocator,
    VkFence*                                    pFence);
```

- **device** is a logical device associated with **display**
- **display** is the display on which the event **may** occur.
- **pDisplayEventInfo** is a pointer to a `VkDisplayEventInfoEXT` structure describing the event of interest to the application.
- **pAllocator** controls host memory allocation as described in the **Memory Allocation** chapter.
- **pFence** is a pointer to a handle in which the resulting fence object is returned.
Valid Usage (Implicit)

- **device** **must** be a valid `VkDevice` handle
- **display** **must** be a valid `VkDisplayKHR` handle
- **pDisplayEventInfo** **must** be a valid pointer to a valid `VkDisplayEventInfoEXT` structure
- If `pAllocator` is not `NULL`, `pAllocator` **must** be a valid pointer to a valid `VkAllocationCallbacks` structure
- **pFence** **must** be a valid pointer to a `VkFence` handle
- Both of **device**, and **display** **must** have been created, allocated, or retrieved from the same `VkPhysicalDevice`

Return Codes

**Success**

- **VK_SUCCESS**

The `VkDisplayEventInfoEXT` structure is defined as:

```c
typedef struct VkDisplayEventInfoEXT {
    VkStructureType          sType;
    const void*              pNext;
    VkDisplayEventTypeEXT    displayEvent;
} VkDisplayEventInfoEXT;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **displayEvent** is a `VkDisplayEventTypeEXT` specifying when the fence will be signaled.

Valid Usage (Implicit)

- **sType** **must** be `VK_STRUCTURE_TYPE_DISPLAY_EVENT_INFO_EXT`
- **pNext** **must** be `NULL`
- **displayEvent** **must** be a valid `VkDisplayEventTypeEXT` value

Possible values of `VkDisplayEventInfoEXT::displayEvent`, specifying when a fence will be signaled, are:
typedef enum VkDisplayEventTypeEXT {
    VK_DISPLAY_EVENT_TYPE_FIRST_PIXEL_OUT_EXT = 0,
} VkDisplayEventTypeEXT;

- **VK_DISPLAY_EVENT_TYPE_FIRST_PIXEL_OUT_EXT** specifies that the fence is signaled when the first pixel of the next display refresh cycle leaves the display engine for the display.

### 6.3.2. Importing Fence Payloads

Applications can import a fence payload into an existing fence using an external fence handle. The effects of the import operation will be either temporary or permanent, as specified by the application. If the import is temporary, the fence will be **restored** to its permanent state the next time that fence is passed to `vkResetFences`.

**Note**

Restoring a fence to its prior permanent payload is a distinct operation from resetting a fence payload. See `vkResetFences` for more detail.

Performing a subsequent temporary import on a fence before resetting it has no effect on this requirement; the next unsignal of the fence **must** still restore its last permanent state. A permanent payload import behaves as if the target fence was destroyed, and a new fence was created with the same handle but the imported payload. Because importing a fence payload temporarily or permanently detaches the existing payload from a fence, similar usage restrictions to those applied to `vkDestroyFence` are applied to any command that imports a fence payload. Which of these import types is used is referred to as the import operation's **permanence**. Each handle type supports either one or both types of permanence.

The implementation **must** perform the import operation by either referencing or copying the payload referred to by the specified external fence handle, depending on the handle's type. The import method used is referred to as the handle type's **transference**. When using handle types with reference transference, importing a payload to a fence adds the fence to the set of all fences sharing that payload. This set includes the fence from which the payload was exported. Fence signaling, waiting, and resetting operations performed on any fence in the set **must** behave as if the set were a single fence. Importing a payload using handle types with copy transference creates a duplicate copy of the payload at the time of import, but makes no further reference to it. Fence signaling, waiting, and resetting operations performed on the target of copy imports **must** not affect any other fence or payload.

Export operations have the same transference as the specified handle type's import operations. Additionally, exporting a fence payload to a handle with copy transference has the same side effects on the source fence's payload as executing a fence reset operation. If the fence was using a temporarily imported payload, the fence's prior permanent payload will be restored.
The tables **Handle Types Supported by VkImportFenceWin32HandleInfoKHR** and **Handle Types Supported by VkImportFenceFdInfoKHR** define the permanence and transference of each handle type.

**External synchronization** allows implementations to modify an object's internal state, i.e. payload, without internal synchronization. However, for fences sharing a payload across processes, satisfying the external synchronization requirements of VkFence parameters as if all fences in the set were the same object is sometimes infeasible. Satisfying valid usage constraints on the state of a fence would similarly require impractical coordination or levels of trust between processes. Therefore, these constraints only apply to a specific fence handle, not to its payload. For distinct fence objects which share a payload:

- If multiple commands which queue a signal operation, or which unsignal a fence, are called concurrently, behavior will be as if the commands were called in an arbitrary sequential order.
- If a queue submission command is called with a fence that is sharing a payload, and the payload is already associated with another queue command that has not yet completed execution, either one or both of the commands will cause the fence to become signaled when they complete execution.
- If a fence payload is reset while it is associated with a queue command that has not yet completed execution, the payload will become unsignaled, but may become signaled again when the command completes execution.
- In the preceding cases, any of the devices associated with the fences sharing the payload may be lost, or any of the queue submission or fence reset commands may return VK_ERROR_INITIALIZATION_FAILED.

Other than these non-deterministic results, behavior is well defined. In particular:

- The implementation must not crash or enter an internally inconsistent state where future valid Vulkan commands might cause undefined results,
- Timeouts on future wait commands on fences sharing the payload must be effective.

These rules allow processes to synchronize access to shared memory without trusting each other. However, such processes must still be cautious not to use the shared fence for more than synchronizing access to the shared memory. For example, a process should not use a fence with shared payload to tell when commands it submitted to a queue have completed and objects used by those commands may be destroyed, since the other process can accidentally or maliciously cause the fence to signal before the commands actually complete.

When a fence is using an imported payload, its VkExportFenceCreateInfo::handleTypes value is that specified when creating the fence from which the payload was exported, rather than that specified when creating the fence. Additionally, VkExternalFenceProperties::exportFromImportedHandleTypes restricts which handle types can be exported from such a fence based on the specific handle type used to import the current payload. Passing a fence to vkAcquireNextImageKHR is equivalent to
temporarily importing a fence payload to that fence.

Note

Because the exportable handle types of an imported fence correspond to its current imported payload, and \texttt{vkAcquireNextImageKHR} behaves the same as a temporary import operation for which the source fence is opaque to the application, applications have no way of determining whether any external handle types \texttt{can} be exported from a fence in this state. Therefore, applications \textbf{must} not attempt to export handles from fences using a temporarily imported payload from \texttt{vkAcquireNextImageKHR}.

When importing a fence payload, it is the responsibility of the application to ensure the external handles meet all valid usage requirements. However, implementations \textbf{must} perform sufficient validation of external handles to ensure that the operation results in a valid fence which will not cause program termination, device loss, queue stalls, host thread stalls, or corruption of other resources when used as allowed according to its import parameters. If the external handle provided does not meet these requirements, the implementation \textbf{must} fail the fence payload import operation with the error code \texttt{VK_ERROR_INVALID_EXTERNAL_HANDLE}.

To import a fence payload from a Windows handle, call:

\begin{verbatim}
VkResult vkImportFenceWin32HandleKHR(
    VkDevice                                    device,
    const VkImportFenceWin32HandleInfoKHR*      pImportFenceWin32HandleInfo);
\end{verbatim}

- \texttt{device} is the logical device that created the fence.
- \texttt{pImportFenceWin32HandleInfo} is a pointer to a \texttt{VkImportFenceWin32HandleInfoKHR} structure specifying the fence and import parameters.

Importing a fence payload from Windows handles does not transfer ownership of the handle to the Vulkan implementation. For handle types defined as NT handles, the application \textbf{must} release ownership using the \texttt{CloseHandle} system call when the handle is no longer needed.

Applications \textbf{can} import the same fence payload into multiple instances of Vulkan, into the same instance from which it was exported, and multiple times into a given Vulkan instance.

\begin{table}
\centering
\begin{tabular}{|c|}
\hline
\textbf{Valid Usage (Implicit)}
\hline
- \texttt{device} \textbf{must} be a valid \texttt{VkDevice} handle
- \texttt{pImportFenceWin32HandleInfo} \textbf{must} be a valid pointer to a valid \texttt{VkImportFenceWin32HandleInfoKHR} structure
\hline
\end{tabular}
\end{table}
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_INVALID_EXTERNAL_HANDLE

The `VkImportFenceWin32HandleInfoKHR` structure is defined as:

```c
typedef struct VkImportFenceWin32HandleInfoKHR {
    VkStructureType                      sType;
    const void*                          pNext;
    VkFence                              fence;
    VkFenceImportFlags                   flags;
    VkExternalFenceHandleTypeFlagBits    handleType;
    HANDLE                               handle;
    LPCWSTR                              name;
} VkImportFenceWin32HandleInfoKHR;
```

• `sType` is the type of this structure.
• `pNext` is `NULL` or a pointer to an extension-specific structure.
• `fence` is the fence into which the state will be imported.
• `flags` is a bitmask of `VkFenceImportFlagBits` specifying additional parameters for the fence payload import operation.
• `handleType` specifies the type of `handle`.
• `handle` is the external handle to import, or `NULL`.
• `name` is a null-terminated UTF-16 string naming the underlying synchronization primitive to import, or `NULL`.

The handle types supported by `handleType` are:

<table>
<thead>
<tr>
<th>Handle Type</th>
<th>Transference</th>
<th>Permanence Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>VK_EXTERNAL_FENCE_HANDLE_TYPE_OPAQUE_WIN32_BIT</td>
<td>Reference</td>
<td>Temporary, Permanent</td>
</tr>
<tr>
<td>VK_EXTERNAL_FENCE_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT</td>
<td>Reference</td>
<td>Temporary, Permanent</td>
</tr>
</tbody>
</table>
Valid Usage

- `handleType` **must** be a value included in the Handle Types Supported by `VkImportFenceWin32HandleInfoKHR` table
- If `handleType` is not `VK_EXTERNAL_FENCE_HANDLE_TYPE_OPAQUE_WIN32_BIT`, name **must** be `NULL`
- If `handleType` is not `0` and `handle` is `NULL`, name **must** name a valid synchronization primitive of the type specified by `handleType`
- If `handleType` is not `0` and name is `NULL`, `handle` **must** be a valid handle of the type specified by `handleType`
- If `handle` is not `NULL`, name **must** be `NULL`
- If `handle` is not `NULL`, it **must** obey any requirements listed for `handleType` in external fence handle types compatibility
- If name is not `NULL`, it **must** obey any requirements listed for `handleType` in external fence handle types compatibility

Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_IMPORT_FENCE_WIN32_HANDLE_INFO_KHR`
- `pNext` **must** be `NULL`
- `fence` **must** be a valid `VkFence` handle
- `flags` **must** be a valid combination of `VkFenceImportFlagBits` values
- If `handleType` is not `0`, `handleType` **must** be a valid `VkExternalFenceHandleTypeFlagBits` value

Host Synchronization

- Host access to `fence` **must** be externally synchronized

To import a fence payload from a POSIX file descriptor, call:

```c
VkResult vkImportFenceFdKHR(
    VkDevice                                    device,
    const VkImportFenceFdInfoKHR*               pImportFenceFdInfo);
```

- `device` is the logical device that created the fence.
- `pImportFenceFdInfo` is a pointer to a `VkImportFenceFdInfoKHR` structure specifying the fence and import parameters.

Importing a fence payload from a file descriptor transfers ownership of the file descriptor from the application to the Vulkan implementation. The application **must** not perform any operations on the file descriptor.
Applications can import the same fence payload into multiple instances of Vulkan, into the same instance from which it was exported, and multiple times into a given Vulkan instance.

### Valid Usage

- fence must not be associated with any queue command that has not yet completed execution on that queue

### Valid Usage (Implicit)

- device must be a valid VkDevice handle
- pImportFenceFdInfo must be a valid pointer to a valid VkImportFenceFdInfoKHR structure

### Return Codes

**Success**

- VK_SUCCESS

**Failure**

- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_INVALID_EXTERNAL_HANDLE

The VkImportFenceFdInfoKHR structure is defined as:

```c
typedef struct VkImportFenceFdInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkFence fence;
    VkFenceImportFlags flags;
    VkExternalFenceHandleTypeFlagBits handleType;
    int fd;
} VkImportFenceFdInfoKHR;
```

- sType is the type of this structure.
- pNext is NULL or a pointer to an extension-specific structure.
- fence is the fence into which the payload will be imported.
- flags is a bitmask of VkFenceImportFlagBits specifying additional parameters for the fence payload import operation.
- handleType specifies the type of fd.
- fd is the external handle to import.
The handle types supported by `handleType` are:

<table>
<thead>
<tr>
<th>Handle Type</th>
<th>Transference</th>
<th>Permanence Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>VK_EXTERNAL_FENCE_HANDLE_TYPE_OPAQUE_FD_BIT</td>
<td>Reference</td>
<td>Temporary,Permanent</td>
</tr>
<tr>
<td>VK_EXTERNAL_FENCE_HANDLE_TYPE_SYNC_FD_BIT</td>
<td>Copy</td>
<td>Temporary</td>
</tr>
</tbody>
</table>

**Valid Usage**

- `handleType` must be a value included in the Handle Types Supported by `VkImportFenceFdInfoKHR` table
- `fd` must obey any requirements listed for `handleType` in external fence handle types compatibility

If `handleType` is `VK_EXTERNAL_FENCE_HANDLE_TYPE_SYNC_FD_BIT`, the special value `-1` for `fd` is treated like a valid sync file descriptor referring to an object that has already signaled. The import operation will succeed and the `VkFence` will have a temporarily imported payload as if a valid file descriptor had been provided.

**Note**

This special behavior for importing an invalid sync file descriptor allows easier interoperability with other system APIs which use the convention that an invalid sync file descriptor represents work that has already completed and does not need to be waited for. It is consistent with the option for implementations to return a `-1` file descriptor when exporting a `VK_EXTERNAL_FENCE_HANDLE_TYPE_SYNC_FD_BIT` from a `VkFence` which is signaled.

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_IMPORT_FENCE_FD_INFO_KHR`
- `pNext` must be `NULL`
- `fence` must be a valid `VkFence` handle
- `flags` must be a valid combination of `VkFenceImportFlagBits` values
- `handleType` must be a valid `VkExternalFenceHandleTypeFlagBits` value

**Host Synchronization**

- Host access to `fence` must be externally synchronized

Bits which can be set in `VkImportFenceWin32HandleInfoKHR::flags` and
VkImportFenceFdInfoKHR::flags specifying additional parameters of a fence import operation are:

```c
typedef enum VkFenceImportFlagBits {
    VK_FENCE_IMPORT_TEMPORARY_BIT = 0x00000001,
    VK_FENCE_IMPORT_TEMPORARY_BIT_KHR = VK_FENCE_IMPORT_TEMPORARY_BIT,
} VkFenceImportFlagBits;
```

or the equivalent

```c
typedef VkFenceImportFlagBits VkFenceImportFlagBitsKHR;
```

- **VK_FENCE_IMPORT_TEMPORARY_BIT** specifies that the fence payload will be imported only temporarily, as described in Importing Fence Payloads, regardless of the permanence of `handleType`.

```c
typedef VkFlags VkFenceImportFlags;
```

or the equivalent

```c
typedef VkFenceImportFlags VkFenceImportFlagsKHR;
```

`VkFenceImportFlags` is a bitmask type for setting a mask of zero or more `VkFenceImportFlagBits`.

### 6.4. Semaphores

Semaphores are a synchronization primitive that can be used to insert a dependency between queue operations or between a queue operation and the host. Binary semaphores have two states: signaled and unsignaled. Timeline semaphores have a monotonically increasing 64-bit unsigned integer payload and are signaled with respect to a particular reference value. A semaphore can be signaled after execution of a queue operation is completed, and a queue operation can wait for a semaphore to become signaled before it begins execution. A timeline semaphore can additionally be signaled from the host with the `vkSignalSemaphore` command and waited on from the host with the `vkWaitSemaphores` command.

As with most objects in Vulkan, semaphores are an interface to internal data which is typically opaque to applications. This internal data is referred to as a semaphore's *payload*.

However, in order to enable communication with agents outside of the current device, it is necessary to be able to export that payload to a commonly understood format, and subsequently import from that format as well.

The internal data of a semaphore may include a reference to any resources and pending work associated with signal or unsignal operations performed on that semaphore object. Mechanisms to import and export that internal data to and from semaphores are provided below. These mechanisms indirectly enable applications to share semaphore state between two or more devices.
semaphores and other synchronization primitives across process and API boundaries.

Semaphores are represented by `VkSemaphore` handles:

\[
\text{VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkSemaphore)}
\]

To create a semaphore, call:

\[
\text{VkResult vkCreateSemaphore(}
\quad \text{VkDevice } \text{device,}
\quad \text{const } \text{VkSemaphoreCreateInfo* } \text{pCreateInfo,}
\quad \text{const } \text{VkAllocationCallbacks* } \text{pAllocator,}
\quad \text{VkSemaphore* } \text{pSemaphore});
\]

- `device` is the logical device that creates the semaphore.
- `pCreateInfo` is a pointer to a `VkSemaphoreCreateInfo` structure containing information about how the semaphore is to be created.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
- `pSemaphore` is a pointer to a handle in which the resulting semaphore object is returned.

## Valid Usage (Implicit)

- `device` **must** be a valid `VkDevice` handle
- `pCreateInfo` **must** be a valid pointer to a valid `VkSemaphoreCreateInfo` structure
- If `pAllocator` is not `NULL`, `pAllocator` **must** be a valid pointer to a valid `VkAllocationCallbacks` structure
- `pSemaphore` **must** be a valid pointer to a `VkSemaphore` handle

## Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

The `VkSemaphoreCreateInfo` structure is defined as:
typedef struct VkSemaphoreCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkSemaphoreCreateFlags flags;
} VkSemaphoreCreateInfo;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• flags is reserved for future use.

### Valid Usage (Implicit)

- sType must be VK_STRUCTURE_TYPE_SEMAPHORE_CREATE_INFO
- Each pNext member of any structure (including this one) in the pNext chain must be either NULL or a pointer to a valid instance of VkExportSemaphoreCreateInfo, VkExportSemaphoreWin32HandleInfoKHR, or VkSemaphoreTypeCreateInfo
- The sType value of each struct in the pNext chain must be unique
- flags must be 0

typedef VkFlags VkSemaphoreCreateFlags;

VkSemaphoreCreateFlags is a bitmask type for setting a mask, but is currently reserved for future use.

To create a semaphore of a specific type, add a VkSemaphoreTypeCreateInfo structure to the pNext chain of the VkSemaphoreCreateInfo structure. The VkSemaphoreTypeCreateInfo structure is defined as:

typedef struct VkSemaphoreTypeCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkSemaphoreType semaphoreType;
    uint64_t initialValue;
} VkSemaphoreTypeCreateInfo;

or the equivalent

typedef VkSemaphoreTypeCreateInfo VkSemaphoreTypeCreateInfoKHR;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• semaphoreType is a VkSemaphoreType value specifying the type of the semaphore.
**Valid Usage (Implicit)**

- **sType** must be `VK_STRUCTURE_TYPE_SEMAPHORE_TYPE_CREATE_INFO`
- **semaphoreType** must be a valid `VkSemaphoreType` value

**Valid Usage**

- If the `timelineSemaphore` feature is not enabled, **semaphoreType** must not equal `VK_SEMAPHORE_TYPE_TIMELINE`
- If `semaphoreType` is `VK_SEMAPHORE_TYPE_BINARY`, **initialValue** must be zero

If no `VkSemaphoreTypeCreateInfo` structure is included in the `pNext` chain of `VkSemaphoreCreateInfo`, then the created semaphore will have a default `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_BINARY`.

Possible values of `VkSemaphoreTypeCreateInfo::semaphoreType`, specifying the type of a semaphore, are:

```cpp
typedef enum VkSemaphoreType {
    VK_SEMAPHORE_TYPE_BINARY = 0,
    VK_SEMAPHORE_TYPE_TIMELINE = 1,
    VK_SEMAPHORE_TYPE_BINARY_KHR = VK_SEMAPHORE_TYPE_BINARY,
    VK_SEMAPHORE_TYPE_TIMELINE_KHR = VK_SEMAPHORE_TYPE_TIMELINE,
} VkSemaphoreType;
```

or the equivalent

```cpp
typedef VkSemaphoreType VkSemaphoreTypeKHR;
```

- **VK_SEMAPHORE_TYPE_BINARY** specifies a *binary semaphore* type that has a boolean payload indicating whether the semaphore is currently signaled or unsignaled. When created, the semaphore is in the unsignaled state.
- **VK_SEMAPHORE_TYPE_TIMELINE** specifies a *timeline semaphore* type that has a monotonically increasing 64-bit unsigned integer payload indicating whether the semaphore is signaled with respect to a particular reference value. When created, the semaphore payload has the value given by the **initialValue** field of `VkSemaphoreTypeCreateInfo`.

To create a semaphore whose payload can be exported to external handles, add a `VkExportSemaphoreCreateInfo` structure to the `pNext` chain of the `VkSemaphoreCreateInfo` structure. The `VkExportSemaphoreCreateInfo` structure is defined as:
typedef struct VkExportSemaphoreCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkExternalSemaphoreHandleTypeFlags handleTypes;
} VkExportSemaphoreCreateInfo;

or the equivalent

typedef VkExportSemaphoreCreateInfo VkExportSemaphoreCreateInfoKHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **handleTypes** is a bitmask of VkExternalSemaphoreHandleTypeFlagBits specifying one or more semaphore handle types the application can export from the resulting semaphore. The application can request multiple handle types for the same semaphore.

**Valid Usage**

- The bits in **handleTypes** must be supported and compatible, as reported by VkExternalSemaphoreProperties

**Valid Usage (Implicit)**

- **sType** must be VK_STRUCTURE_TYPE_EXPORT_SEMAPHORE_CREATE_INFO
- **handleTypes** must be a valid combination of VkExternalSemaphoreHandleTypeFlagBits values

To specify additional attributes of NT handles exported from a semaphore, add a VkExportSemaphoreWin32HandleInfoKHR structure to the **pNext** chain of the VkSemaphoreCreateInfo structure. The VkExportSemaphoreWin32HandleInfoKHR structure is defined as:

typedef struct VkExportSemaphoreWin32HandleInfoKHR {
    VkStructureType sType;
    const void* pNext;
    const SECURITY_ATTRIBUTES* pAttributes;
    DWORD dwAccess;
    LPCWSTR name;
} VkExportSemaphoreWin32HandleInfoKHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **pAttributes** is a pointer to a Windows SECURITY_ATTRIBUTES structure specifying security
attributes of the handle.

- **dwAccess** is a DWORD specifying access rights of the handle.
- **name** is a null-terminated UTF-16 string to associate with the underlying synchronization primitive referenced by NT handles exported from the created semaphore.

If `VkExportSemaphoreCreateInfo` is not present in the same `pNext` chain, this structure is ignored.

If `VkExportSemaphoreCreateInfo` is present in the `pNext` chain of `VkSemaphoreCreateInfo` with a Windows `handleType`, but either `VkExportSemaphoreWin32HandleInfoKHR` is not present in the `pNext` chain, or if it is but `pAttributes` is set to NULL, default security descriptor values will be used, and child processes created by the application will not inherit the handle, as described in the MSDN documentation for “Synchronization Object Security and Access Rights”. Further, if the structure is not present, the access rights used depend on the handle type.

For handles of the following types:

- **VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_WIN32_BIT**

  The implementation must ensure the access rights allow both signal and wait operations on the semaphore.

For handles of the following types:

- **VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_D3D12_FENCE_BIT**

  The access rights must be:

  GENERIC_ALL

1

### Valid Usage

- If `VkExportSemaphoreCreateInfo::handleTypes` does not include `VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_WIN32_BIT` or `VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_D3D12_FENCE_BIT`, `VkExportSemaphoreWin32HandleInfoKHR` must not be included in the `pNext` chain of `VkSemaphoreCreateInfo`

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_EXPORT_SEMAPHORE_WIN32_HANDLE_INFO_KHR`
- If `pAttributes` is not NULL, `pAttributes` must be a valid pointer to a valid `SECURITY_ATTRIBUTES` value

To export a Windows handle representing the payload of a semaphore, call:
VkResult vkGetSemaphoreWin32HandleKHR(
    VkDevice                                    device,
    const VkSemaphoreGetWin32HandleInfoKHR*     pGetWin32HandleInfo,
    HANDLE*                                     pHandle);

• **device** is the logical device that created the semaphore being exported.
• **pGetWin32HandleInfo** is a pointer to a **VkSemaphoreGetWin32HandleInfoKHR** structure containing parameters of the export operation.
• **pHandle** will return the Windows handle representing the semaphore state.

For handle types defined as NT handles, the handles returned by `vkGetSemaphoreWin32HandleKHR` are owned by the application. To avoid leaking resources, the application **must** release ownership of them using the `CloseHandle` system call when they are no longer needed.

Exporting a Windows handle from a semaphore **may** have side effects depending on the transference of the specified handle type, as described in **Importing Semaphore Payloads**.

### Valid Usage (Implicit)

- **device** must be a valid **VkDevice** handle
- **pGetWin32HandleInfo** must be a valid pointer to a valid **VkSemaphoreGetWin32HandleInfoKHR** structure
- **pHandle** must be a valid pointer to a **HANDLE** value

### Return Codes

**Success**

- **VK_SUCCESS**

**Failure**

- **VK_ERROR_TOO_MANY_OBJECTS**
- **VK_ERROR_OUT_OF_HOST_MEMORY**

The **VkSemaphoreGetWin32HandleInfoKHR** structure is defined as:

```c
typedef struct VkSemaphoreGetWin32HandleInfoKHR {
    VkStructureType                          sType;
    const void*                              pNext;
    VkSemaphore                              semaphore;
    VkExternalSemaphoreHandleTypeFlagBits    handleType;
} VkSemaphoreGetWin32HandleInfoKHR;
```

• **sType** is the type of this structure.
• **pNext** is NULL or a pointer to an extension-specific structure.

• **semaphore** is the semaphore from which state will be exported.

• **handleType** is the type of handle requested.

The properties of the handle returned depend on the value of **handleType**. See **VkExternalSemaphoreHandleTypeFlagBits** for a description of the properties of the defined external semaphore handle types.

### Valid Usage

- **handleType** must have been included in **VkExportSemaphoreCreateInfo::handleTypes** when the **semaphore**'s current payload was created.

- If **handleType** is defined as an NT handle, **vkGetSemaphoreWin32HandleKHR** must be called no more than once for each valid unique combination of **semaphore** and **handleType**.

- **semaphore** must not currently have its payload replaced by an imported payload as described below in **Importing Semaphore Payloads** unless that imported payload's handle type was included in **VkExternalSemaphoreProperties::exportFromImportedHandleTypes** for **handleType**.

- If **handleType** refers to a handle type with copy payload transference semantics, as defined below in **Importing Semaphore Payloads**, there must be no queue waiting on **semaphore**.

- If **handleType** refers to a handle type with copy payload transference semantics, **semaphore** must be signaled, or have an associated **semaphore signal operation** pending execution.

- **handleType** must be defined as an NT handle or a global share handle.

### Valid Usage (Implicit)

- **sType** must be **VK_STRUCTURE_TYPE_SEMAPHORE_GET_WIN32_HANDLE_INFO_KHR**.

- **pNext** must be NULL.

- **semaphore** must be a valid **VkSemaphore** handle.

- **handleType** must be a valid **VkExternalSemaphoreHandleTypeFlagBits** value.

To export a POSIX file descriptor representing the payload of a semaphore, call:

```c
VkResult vkGetSemaphoreFdKHR(
    VkDevice device,
    const VkSemaphoreGetFdInfoKHR* pGetFdInfo,
    int* pFd);
```

- **device** is the logical device that created the semaphore being exported.

- **pGetFdInfo** is a pointer to a **VkSemaphoreGetFdInfoKHR** structure containing parameters of the export operation.
• `pFd` will return the file descriptor representing the semaphore payload.

Each call to `vkGetSemaphoreFdKHR` must create a new file descriptor and transfer ownership of it to the application. To avoid leaking resources, the application must release ownership of the file descriptor when it is no longer needed.

**Note**
Ownership can be released in many ways. For example, the application can call `close()` on the file descriptor, or transfer ownership back to Vulkan by using the file descriptor to import a semaphore payload.

Where supported by the operating system, the implementation must set the file descriptor to be closed automatically when an `execve` system call is made.

Exporting a file descriptor from a semaphore may have side effects depending on the transference of the specified handle type, as described in **Importing Semaphore State**.

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pGetFdInfo` must be a valid pointer to a valid `VkSemaphoreGetFdInfoKHR` structure
- `pFd` must be a valid pointer to an `int` value

### Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_TOO_MANY_OBJECTS`
- `VK_ERROR_OUT_OF_HOST_MEMORY`

The `VkSemaphoreGetFdInfoKHR` structure is defined as:

```c
typedef struct VkSemaphoreGetFdInfoKHR {
    VkStructureType                          sType;
    const void*                              pNext;
    VkSemaphore                              semaphore;
    VkExternalSemaphoreHandleTypeFlagBits    handleType;
} VkSemaphoreGetFdInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
• **semaphore** is the semaphore from which state will be exported.

• **handleType** is the type of handle requested.

The properties of the file descriptor returned depend on the value of **handleType**. See `VkExternalSemaphoreHandleTypeFlagBits` for a description of the properties of the defined external semaphore handle types.

**Valid Usage**

• **handleType must** have been included in `VkExportSemaphoreCreateInfo::handleTypes` when **semaphore**'s current payload was created.

• **semaphore must** not currently have its payload replaced by an imported payload as described below in Importing Semaphore Payloads unless that imported payload's handle type was included in `VkExternalSemaphoreProperties::exportFromImportedHandleTypes` for **handleType**.

• If **handleType** refers to a handle type with copy payload transference semantics, as defined below in Importing Semaphore Payloads, there must be no queue waiting on **semaphore**.

• If **handleType** refers to a handle type with copy payload transference semantics, **semaphore** must be signaled, or have an associated **semaphore signal operation** pending execution.

• **handleType must** be defined as a POSIX file descriptor handle.

• If **handleType** refers to a handle type with copy payload transference semantics, **semaphore** must have been created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_BINARY`.

• If **handleType** refers to a handle type with copy payload transference semantics, **semaphore** must have an associated semaphore signal operation that has been submitted for execution and any semaphore signal operations on which it depends (if any) must have also been submitted for execution.

**Valid Usage (Implicit)**

• **sType must** be `VK_STRUCTURE_TYPE_SEMAPHORE_GET_FD_INFO_KHR`.

• **pNext must** be `NULL`.

• **semaphore must** be a valid `VkSemaphore` handle.

• **handleType must** be a valid `VkExternalSemaphoreHandleTypeFlagBits` value.

To destroy a semaphore, call:

```c
void vkDestroySemaphore(
    VkDevice device,
    VkSemaphore semaphore,
    const VkAllocationCallbacks* pAllocator);
```

• **device** is the logical device that destroys the semaphore.
• semaphore is the handle of the semaphore to destroy.
• pAllocator controls host memory allocation as described in the Memory Allocation chapter.

**Valid Usage**

- All submitted batches that refer to semaphore must have completed execution.
- If VkAllocationCallbacks were provided when semaphore was created, a compatible set of callbacks must be provided here.
- If no VkAllocationCallbacks were provided when semaphore was created, pAllocator must be NULL.

**Valid Usage (Implicit)**

- device must be a valid VkDevice handle.
- If semaphore is not VK_NULL_HANDLE, semaphore must be a valid VkSemaphore handle.
- If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure.
- If semaphore is a valid handle, it must have been created, allocated, or retrieved from device.

**Host Synchronization**

- Host access to semaphore must be externally synchronized.

### 6.4.1. Semaphore Signaling

When a batch is submitted to a queue via a queue submission, and it includes semaphores to be signaled, it defines a memory dependency on the batch, and defines semaphore signal operations which set the semaphores to the signaled state.

In case of semaphores created with a VkSemaphoreType of VK_SEMAPHORE_TYPE_TIMELINE the semaphore is considered signaled with respect to the counter value set to be signaled as specified in VkTimelineSemaphoreSubmitInfo or VkSemaphoreSignalInfo.

The first synchronization scope includes every command submitted in the same batch. Semaphore signal operations that are defined by vkQueueSubmit additionally include all commands that occur earlier in submission order. Semaphore signal operations that are defined by vkQueueSubmit or vkQueueBindSparse additionally include in the first synchronization scope any semaphore and fence signal operations that occur earlier in signal operation order.

The second synchronization scope includes only the semaphore signal operation.

The first access scope includes all memory access performed by the device.
The second access scope is empty.

### 6.4.2. Semaphore Waiting

When a batch is submitted to a queue via a queue submission, and it includes semaphores to be waited on, it defines a memory dependency between prior semaphore signal operations and the batch, and defines semaphore wait operations.

Such semaphore wait operations set the semaphores created with a VkSemaphoreType of VK_SEMAPHORE_TYPE_BINARY to the unsignaled state. In case of semaphores created with a VkSemaphoreType of VK_SEMAPHORE_TYPE_TIMELINE a prior semaphore signal operation defines a memory dependency with a semaphore wait operation if the value the semaphore is signaled with is greater than or equal to the value the semaphore is waited with, thus the semaphore will continue to be considered signaled with respect to the counter value waited on as specified in VkTimelineSemaphoreSubmitInfo.

The first synchronization scope includes all semaphore signal operations that operate on semaphores waited on in the same batch, and that happen-before the wait completes.

The second synchronization scope includes every command submitted in the same batch. In the case of vkQueueSubmit, the second synchronization scope is limited to operations on the pipeline stages determined by the destination stage mask specified by the corresponding element of pWaitDstStageMask. Also, in the case of vkQueueSubmit, the second synchronization scope additionally includes all commands that occur later in submission order.

The first access scope is empty.

The second access scope includes all memory access performed by the device.

The semaphore wait operation happens-after the first set of operations in the execution dependency, and happens-before the second set of operations in the execution dependency.

---

**Note**

Unlike timeline semaphores, fences or events, the act of waiting for a binary semaphore also unsignals that semaphore. Applications **must** ensure that between two such wait operations, the semaphore is signaled again, with execution dependencies used to ensure these occur in order. Binary semaphore waits and signals should thus occur in discrete 1:1 pairs.
A common scenario for using `pWaitDstStageMask` with values other than `VK_PIPELINE_STAGE_ALL_COMMANDS_BIT` is when synchronizing a window system presentation operation against subsequent command buffers which render the next frame. In this case, a presentation image **must** not be overwritten until the presentation operation completes, but other pipeline stages **can** execute without waiting. A mask of `VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT` prevents subsequent color attachment writes from executing until the semaphore signals. Some implementations **may** be able to execute transfer operations and/or vertex processing work before the semaphore is signaled.

If an image layout transition needs to be performed on a presentable image before it is used in a framebuffer, that **can** be performed as the first operation submitted to the queue after acquiring the image, and **should** not prevent other work from overlapping with the presentation operation. For example, a `VkImageMemoryBarrier` could use:

- `srcStageMask = VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT`
- `srcAccessMask = 0`
- `dstStageMask = VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT`
- `dstAccessMask = VK_ACCESS_COLOR_ATTACHMENT_READ_BIT | VK_ACCESS_COLOR_ATTACHMENT_WRITE_BIT`.
- `oldLayout = VK_IMAGE_LAYOUT_PRESENT_SRC_KHR`
- `newLayout = VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL`

Alternatively, `oldLayout` **can** be `VK_IMAGE_LAYOUT_UNDEFINED`, if the image's contents need not be preserved.

This barrier accomplishes a dependency chain between previous presentation operations and subsequent color attachment output operations, with the layout transition performed in between, and does not introduce a dependency between previous work and any vertex processing stages. More precisely, the semaphore signals after the presentation operation completes, the semaphore wait stalls the `VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT` stage, and there is a dependency from that same stage to itself with the layout transition performed in between.

### 6.4.3. Semaphore State Requirements For Wait Operations

Before waiting on a semaphore, the application **must** ensure the semaphore is in a valid state for a wait operation. Specifically, when a semaphore wait operation is submitted to a queue:

- A binary semaphore **must** be signaled, or have an associated semaphore signal operation that is pending execution.
- Any semaphore signal operations on which the pending binary semaphore signal operation depends **must** also be completed or pending execution.
- There **must** be no other queue waiting on the same binary semaphore when the operation
executes.

6.4.4. Host Operations on Semaphores

In addition to semaphore signal operations and semaphore wait operations submitted to device queues, timeline semaphores support the following host operations:

• Query the current counter value of the semaphore using the vkGetSemaphoreCounterValue command.

• Wait for a set of semaphores to reach particular counter values using the vkWaitSemaphores command.

• Signal the semaphore with a particular counter value from the host using the vkSignalSemaphore command.

To query the current counter value of a semaphore created with a VkSemaphoreType of VK_SEMAPHORE_TYPE_TIMELINE from the host, call:

```c
VkResult vkGetSemaphoreCounterValueKHR(
    VkDevice                                    device,
    VkSemaphore                                 semaphore,
    uint64_t*                                   pValue);
```

• device is the logical device that owns the semaphore.

• semaphore is the handle of the semaphore to query.

• pValue is a pointer to a 64-bit integer value in which the current counter value of the semaphore is returned.

Note

If a queue submission command is pending execution, then the value returned by this command may immediately be out of date.

Valid Usage

• semaphore must have been created with a VkSemaphoreType of VK_SEMAPHORE_TYPE_TIMELINE

Valid Usage (Implicit)

• device must be a valid VkDevice handle

• semaphore must be a valid VkSemaphore handle

• pValue must be a valid pointer to a uint64_t value

• semaphore must have been created, allocated, or retrieved from device
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY
• VK_ERROR_DEVICE_LOST

To wait for a set of semaphores created with a VkSemaphoreType of VK_SEMAPHORE_TYPE_TIMELINE to reach particular counter values on the host, call:

```
VkResult vkWaitSemaphoresKHR(
    VkDevice device,
    const VkSemaphoreWaitInfo* pWaitInfo,
    uint64_t timeout);
```

• `device` is the logical device that owns the semaphore.
• `pWaitInfo` is a pointer to a VkSemaphoreWaitInfo structure containing information about the wait condition.
• `timeout` is the timeout period in units of nanoseconds. `timeout` is adjusted to the closest value allowed by the implementation-dependent timeout accuracy, which may be substantially longer than one nanosecond, and may be longer than the requested period.

If the condition is satisfied when `vkWaitSemaphores` is called, then `vkWaitSemaphores` returns immediately. If the condition is not satisfied at the time `vkWaitSemaphores` is called, then `vkWaitSemaphores` will block and wait up to `timeout` nanoseconds for the condition to become satisfied.

If `timeout` is zero, then `vkWaitSemaphores` does not wait, but simply returns information about the current state of the semaphore. VK_TIMEOUT will be returned in this case if the condition is not satisfied, even though no actual wait was performed.

If the specified timeout period expires before the condition is satisfied, `vkWaitSemaphores` returns VK_TIMEOUT. If the condition is satisfied before `timeout` nanoseconds has expired, `vkWaitSemaphores` returns VK_SUCCESS.

If device loss occurs (see Lost Device) before the timeout has expired, `vkWaitSemaphores` must return in finite time with either VK_SUCCESS or VK_ERROR_DEVICE_LOST.
Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pWaitInfo` must be a valid pointer to a valid `VkSemaphoreWaitInfo` structure

Return Codes

Success

- `VK_SUCCESS`
- `VK_TIMEOUT`

Failure

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`
- `VK_ERROR_DEVICE_LOST`

The `VkSemaphoreWaitInfo` structure is defined as:

```c
typedef struct VkSemaphoreWaitInfo {
    VkStructureType         sType;
    const void*             pNext;
    VkSemaphoreWaitFlags    flags;
    uint32_t                semaphoreCount;
    const VkSemaphore*      pSemaphores;
    const uint64_t*         pValues;
} VkSemaphoreWaitInfo;
```

or the equivalent

```c
typedef VkSemaphoreWaitInfo VkSemaphoreWaitInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `flags` is a bitmask of `VkSemaphoreWaitFlagBits` specifying additional parameters for the semaphore wait operation.
- `semaphoreCount` is the number of semaphores to wait on.
- `pSemaphores` is a pointer to an array of `semaphoreCount` semaphore handles to wait on.
- `pValues` is a pointer to an array of `semaphoreCount` timeline semaphore values.
**Valid Usage**

- All of the elements of `pSemaphores` **must** reference a semaphore that was created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE`.

**Valid Usage (Implicit)**

- `sType` **must** be `VK_STRUCTURE_TYPE_SEMAPHORE_WAIT_INFO`
- `pNext` **must** be `NULL`
- `flags` **must** be a valid combination of `VkSemaphoreWaitFlagBits` values
- `pSemaphores` **must** be a valid pointer to an array of `semaphoreCount` valid `VkSemaphore` handles
- `pValues` **must** be a valid pointer to an array of `semaphoreCount uint64_t` values
- `semaphoreCount` **must** be greater than 0

Bits which **can** be set in `VkSemaphoreWaitInfo::flags`, specifying additional parameters of a semaphore wait operation, are:

```c
typedef enum VkSemaphoreWaitFlagBits {
    VK_SEMAPHORE_WAIT_ANY_BIT = 0x00000001,
    VK_SEMAPHORE_WAIT_ANY_BIT_KHR = VK_SEMAPHORE_WAIT_ANY_BIT,
} VkSemaphoreWaitFlagBits;
```

or the equivalent

```c
typedef VkSemaphoreWaitFlagBits VkSemaphoreWaitFlagBitsKHR;
```

- `VK_SEMAPHORE_WAIT_ANY_BIT` specifies that the semaphore wait condition is that at least one of the semaphores in `VkSemaphoreWaitInfo::pSemaphores` has reached the value specified by the corresponding element of `VkSemaphoreWaitInfo::pValues`. If `VK_SEMAPHORE_WAIT_ANY_BIT` is not set, the semaphore wait condition is that all of the semaphores in `VkSemaphoreWaitInfo::pSemaphores` have reached the value specified by the corresponding element of `VkSemaphoreWaitInfo::pValues`.

```c
typedef VkFlags VkSemaphoreWaitFlags;
```

or the equivalent

```c
typedef VkSemaphoreWaitFlags VkSemaphoreWaitFlagsKHR;
```

`VkSemaphoreWaitFlags` is a bitmask type for setting a mask of zero or more
To signal a semaphore created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE` with a particular counter value, on the host, call:

```cpp
VkResult vkSignalSemaphoreKHR(
    VkDevice device,
    const VkSemaphoreSignalInfo* pSignalInfo);
```

- `device` is the logical device that owns the semaphore.
- `pSignalInfo` is a pointer to a `VkSemaphoreSignalInfo` structure containing information about the signal operation.

When `vkSignalSemaphore` is executed on the host, it defines and immediately executes a semaphore signal operation which sets the timeline semaphore to the given value.

The first synchronization scope is defined by the host execution model, but includes execution of `vkSignalSemaphore` on the host and anything that happened-before it.

The second synchronization scope is empty.

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pSignalInfo` must be a valid pointer to a valid `VkSemaphoreSignalInfo` structure

### Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

The `VkSemaphoreSignalInfo` structure is defined as:

```c
typedef struct VkSemaphoreSignalInfo {
    VkStructureType sType;
    const void* pNext;
    VkSemaphore semaphore;
    uint64_t value;
} VkSemaphoreSignalInfo;
```
or the equivalent

typedef VkSemaphoreSignalInfo VkSemaphoreSignalInfoKHR;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `semaphore` is the handle of the semaphore to signal.
- `value` is the value to signal.

**Valid Usage**
- `semaphore` must have been created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE`
- `value` must have a value greater than the current value of the semaphore
- `value` must be less than the value of any pending semaphore signal operations
- `value` must have a value which does not differ from the current value of the semaphore or the value of any outstanding semaphore wait or signal operation on `semaphore` by more than `maxTimelineSemaphoreValueDifference`

**Valid Usage (Implicit)**
- `sType` must be `VK_STRUCTURE_TYPE_SEMAPHORE_SIGNAL_INFO`
- `pNext` must be `NULL`
- `semaphore` must be a valid `VkSemaphore` handle

### 6.4.5. Importing Semaphore Payloads

Applications **can** import a semaphore payload into an existing semaphore using an external semaphore handle. The effects of the import operation will be either temporary or permanent, as specified by the application. If the import is temporary, the implementation **must** restore the semaphore to its prior permanent state after submitting the next semaphore wait operation. Performing a subsequent temporary import on a semaphore before performing a semaphore wait has no effect on this requirement; the next wait submitted on the semaphore **must** still restore its last permanent state. A permanent payload import behaves as if the target semaphore was destroyed, and a new semaphore was created with the same handle but the imported payload. Because importing a semaphore payload temporarily or permanently detaches the existing payload from a semaphore, similar usage restrictions to those applied to `vkDestroySemaphore` are applied to any command that imports a semaphore payload. Which of these import types is used is referred to as the import operation’s **permanence**. Each handle type supports either one or both types of permanence.

The implementation **must** perform the import operation by either referencing or copying the
payload referred to by the specified external semaphore handle, depending on the handle's type. The import method used is referred to as the handle type's transference. When using handle types with reference transference, importing a payload to a semaphore adds the semaphore to the set of all semaphores sharing that payload. This set includes the semaphore from which the payload was exported. Semaphore signaling and waiting operations performed on any semaphore in the set must behave as if the set were a single semaphore. Importing a payload using handle types with copy transference creates a duplicate copy of the payload at the time of import, but makes no further reference to it. Semaphore signaling and waiting operations performed on the target of copy imports must not affect any other semaphore or payload.

Export operations have the same transference as the specified handle type's import operations. Additionally, exporting a semaphore payload to a handle with copy transference has the same side effects on the source semaphore's payload as executing a semaphore wait operation. If the semaphore was using a temporarily imported payload, the semaphore’s prior permanent payload will be restored.

Note

The tables Handle Types Supported by VkImportSemaphoreWin32HandleInfoKHR and Handle Types Supported by VkImportSemaphoreFdInfoKHR define the permanence and transference of each handle type.

External synchronization allows implementations to modify an object's internal state, i.e. payload, without internal synchronization. However, for semaphores sharing a payload across processes, satisfying the external synchronization requirements of VkSemaphore parameters as if all semaphores in the set were the same object is sometimes infeasible. Satisfying the wait operation state requirements would similarly require impractical coordination or levels of trust between processes. Therefore, these constraints only apply to a specific semaphore handle, not to its payload. For distinct semaphore objects which share a payload, if the semaphores are passed to separate queue submission commands concurrently, behavior will be as if the commands were called in an arbitrary sequential order. If the wait operation state requirements are violated for the shared payload by a queue submission command, or if a signal operation is queued for a shared payload that is already signaled or has a pending signal operation, effects must be limited to one or more of the following:

- Returning VK_ERROR_INITIALIZATION_FAILED from the command which resulted in the violation.
- Losing the logical device on which the violation occurred immediately or at a future time, resulting in a VK_ERROR_DEVICE_LOST error from subsequent commands, including the one causing the violation.
- Continuing execution of the violating command or operation as if the semaphore wait completed successfully after an implementation-dependent timeout. In this case, the state of the payload becomes undefined, and future operations on semaphores sharing the payload will be subject to these same rules. The semaphore must be destroyed or have its payload replaced by an import operation to again have a well-defined state.
These rules allow processes to synchronize access to shared memory without trusting each other. However, such processes must still be cautious not to use the shared semaphore for more than synchronizing access to the shared memory. For example, a process should not use a shared semaphore as part of an execution dependency chain that, when complete, leads to objects being destroyed, if it does not trust other processes sharing the semaphore payload.

When a semaphore is using an imported payload, its `VkExportSemaphoreCreateInfo::handleTypes` value is that specified when creating the semaphore from which the payload was exported, rather than that specified when creating the semaphore. Additionally, `VkExternalSemaphoreProperties::exportFromImportedHandleTypes` restricts which handle types can be exported from such a semaphore based on the specific handle type used to import the current payload. Passing a semaphore to `vkAcquireNextImageKHR` is equivalent to temporarily importing a semaphore payload to that semaphore.

Because the exportable handle types of an imported semaphore correspond to its current imported payload, and `vkAcquireNextImageKHR` behaves the same as a temporary import operation for which the source semaphore is opaque to the application, applications have no way of determining whether any external handle types can be exported from a semaphore in this state. Therefore, applications must not attempt to export external handles from semaphores using a temporarily imported payload from `vkAcquireNextImageKHR`.

When importing a semaphore payload, it is the responsibility of the application to ensure the external handles meet all valid usage requirements. However, implementations must perform sufficient validation of external handles to ensure that the operation results in a valid semaphore which will not cause program termination, device loss, queue stalls, or corruption of other resources when used as allowed according to its import parameters, and excepting those side effects allowed for violations of the valid semaphore state for wait operations rules. If the external handle provided does not meet these requirements, the implementation must fail the semaphore payload import operation with the error code `VK_ERROR_INVALID_EXTERNAL_HANDLE`.

In addition, when importing a semaphore payload that is not compatible with the payload type corresponding to the `VkSemaphoreType` the semaphore was created with, the implementation may fail the semaphore payload import operation with the error code `VK_ERROR_INVALID_EXTERNAL_HANDLE`.

As the introduction of the external semaphore handle type `VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_D3D12_FENCE_BIT` predates that of timeline semaphores, support for importing semaphore payloads from external handles of that type into semaphores created (implicitly or explicitly) with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_BINARY` is preserved for backwards compatibility. However, applications should prefer importing such handle types into semaphores created with a `VkSemaphoreType` of `VK_SEMAPHORE_TYPE_TIMELINE`.
To import a semaphore payload from a Windows handle, call:

```c
VkResult vkImportSemaphoreWin32HandleKHR(
    VkDevice                                    device,
    const VkImportSemaphoreWin32HandleInfoKHR*  pImportSemaphoreWin32HandleInfo);
```

- `device` is the logical device that created the semaphore.
- `pImportSemaphoreWin32HandleInfo` is a pointer to a `VkImportSemaphoreWin32HandleInfoKHR` structure specifying the semaphore and import parameters.

Importing a semaphore payload from Windows handles does not transfer ownership of the handle to the Vulkan implementation. For handle types defined as NT handles, the application must release ownership using the `CloseHandle` system call when the handle is no longer needed.

Applications can import the same semaphore payload into multiple instances of Vulkan, into the same instance from which it was exported, and multiple times into a given Vulkan instance.

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pImportSemaphoreWin32HandleInfo` must be a valid pointer to a valid `VkImportSemaphoreWin32HandleInfoKHR` structure

Return Codes

Success

- `VK_SUCCESS`

Failure

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_INVALID_EXTERNAL_HANDLE`

The `VkImportSemaphoreWin32HandleInfoKHR` structure is defined as:

```c
typedef struct VkImportSemaphoreWin32HandleInfoKHR {
    VkStructureType                          sType;            
    const void*                              pNext;           
    VkSemaphore                              semaphore;        
    VkSemaphoreImportFlags                   flags;            
    VkExternalSemaphoreHandleTypeFlagBits    handleType;       
    HANDLE                                   handle;          
    LPCWSTR                                   name;            
} VkImportSemaphoreWin32HandleInfoKHR;
```
• **sType** is the type of this structure.
• **pNext** is **NULL** or a pointer to an extension-specific structure.
• **semaphore** is the semaphore into which the payload will be imported.
• **flags** is a bitmask of `VkSemaphoreImportFlagBits` specifying additional parameters for the semaphore payload import operation.
• **handleType** specifies the type of **handle**.
• **handle** is the external handle to import, or **NULL**.
• **name** is a null-terminated UTF-16 string naming the underlying synchronization primitive to import, or **NULL**.

The handle types supported by **handleType** are:

**Table 8. Handle Types Supported by VkImportSemaphoreWin32HandleInfoKHR**

<table>
<thead>
<tr>
<th>Handle Type</th>
<th>Transference</th>
<th>Permanence Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_WIN32_BIT</td>
<td>Reference</td>
<td>Temporary,Permanent</td>
</tr>
<tr>
<td>VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT</td>
<td>Reference</td>
<td>Temporary,Permanent</td>
</tr>
<tr>
<td>VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_D3D12_FENCE_BIT</td>
<td>Reference</td>
<td>Temporary,Permanent</td>
</tr>
</tbody>
</table>
Valid Usage

- **handleType** must be a value included in the Handle Types Supported by VkImportSemaphoreWin32HandleInfoKHR table.
- If **handleType** is not VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_WIN32_BIT or VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_D3D12_FENCE_BIT, **name** must be NULL.
- If **handleType** is not 0 and **handle** is NULL, **name** must name a valid synchronization primitive of the type specified by **handleType**.
- If **handleType** is not 0 and **name** is NULL, **handle** must be a valid handle of the type specified by **handleType**.
- If **handle** is not NULL, **name** must be NULL.
- If **handle** is not NULL, it must obey any requirements listed for **handleType** in external semaphore handle types compatibility.
- If **name** is not NULL, it must obey any requirements listed for **handleType** in external semaphore handle types compatibility.
- If **handleType** is VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_WIN32_BIT or VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT, the VkSemaphoreCreateInfo::flags field must match that of the semaphore from which **handle** or **name** was exported.
- If **handleType** is VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_WIN32_BIT or VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT, the VkSemaphoreTypeCreateInfo::semaphoreType field must match that of the semaphore from which **handle** or **name** was exported.
- If **flags** contains VK_SEMAPHORE_IMPORT_TEMPORARY_BIT, the VkSemaphoreTypeCreateInfo::semaphoreType field of the semaphore from which **handle** or **name** was exported must not be VK_SEMAPHORE_TYPE_TIMELINE.

Valid Usage (Implicit)

- **sType** must be VK_STRUCTURE_TYPE_IMPORT_SEMAPHORE_WIN32_HANDLE_INFO_KHR.
- **pNext** must be NULL.
- **semaphore** must be a valid VkSemaphore handle.
- **flags** must be a valid combination of VkSemaphoreImportFlagBits values.
- If **handleType** is not 0, **handleType** must be a valid VkExternalSemaphoreHandleTypeFlagBits value.

Host Synchronization

- Host access to **semaphore** must be externally synchronized.
To import a semaphore payload from a POSIX file descriptor, call:

```c
VkResult vkImportSemaphoreFdKHR(
    VkDevice device,
    const VkImportSemaphoreFdInfoKHR* pImportSemaphoreFdInfo);
```

- `device` is the logical device that created the semaphore.
- `pImportSemaphoreFdInfo` is a pointer to a `VkImportSemaphoreFdInfoKHR` structure specifying the semaphore and import parameters.

Importing a semaphore payload from a file descriptor transfers ownership of the file descriptor from the application to the Vulkan implementation. The application **must** not perform any operations on the file descriptor after a successful import.

Applications **can** import the same semaphore payload into multiple instances of Vulkan, into the same instance from which it was exported, and multiple times into a given Vulkan instance.

### Valid Usage

- `semaphore` **must** not be associated with any queue command that has not yet completed execution on that queue

### Valid Usage (Implicit)

- `device` **must** be a valid `VkDevice` handle
- `pImportSemaphoreFdInfo` **must** be a valid pointer to a valid `VkImportSemaphoreFdInfoKHR` structure

### Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_INVALID_EXTERNAL_HANDLE`

The `VkImportSemaphoreFdInfoKHR` structure is defined as:
typedef struct VkImportSemaphoreFdInfoKHR {
    VkStructureType                          sType;
    const void*                              pNext;
    VkSemaphore                              semaphore;
    VkSemaphoreImportFlags                   flags;
    VkExternalSemaphoreHandleTypeFlagBits    handleType;
    int                                        fd;
} VkImportSemaphoreFdInfoKHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **semaphore** is the semaphore into which the payload will be imported.
- **flags** is a bitmask of VkSemaphoreImportFlagBits specifying additional parameters for the semaphore payload import operation.
- **handleType** specifies the type of **fd**.
- **fd** is the external handle to import.

The handle types supported by **handleType** are:

<table>
<thead>
<tr>
<th>Handle Type</th>
<th>Transference</th>
<th>Permanence Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_FD_BIT</td>
<td>Reference</td>
<td>Temporary, Permanent</td>
</tr>
<tr>
<td>VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_SYNC_FD_BIT</td>
<td>Copy</td>
<td>Temporary</td>
</tr>
</tbody>
</table>

**Valid Usage**

- **handleType** must be a value included in the Handle Types Supported by VkImportSemaphoreFdInfoKHR table
- **fd** must obey any requirements listed for **handleType** in external semaphore handle types compatibility
- If **handleType** is VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_FD_BIT, the VkSemaphoreCreateInfo::flags field must match that of the semaphore from which **fd** was exported
- If **handleType** is VK_EXTERNAL_SEMAPHORE_HANDLE_TYPE_OPAQUE_FD_BIT, the VkSemaphoreTypeCreateInfo::semaphoreType field must match that of the semaphore from which **fd** was exported
- If **flags** contains VK_SEMAPHORE_IMPORT_TEMPORARY_BIT, the VkSemaphoreTypeCreateInfo::semaphoreType field of the semaphore from which **fd** was exported must not be VK_SEMAPHORE_TYPE_TIMELINE
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_IMPORT_SEMAPHORE_FD_INFO_KHR`
- **pNext** must be `NULL`
- **semaphore** must be a valid `VkSemaphore` handle
- **flags** must be a valid combination of `VkSemaphoreImportFlagBits` values
- **handleType** must be a valid `VkExternalSemaphoreHandleTypeFlagBits` value

Host Synchronization

- Host access to **semaphore** must be externally synchronized

Additional parameters of a semaphore import operation are specified by `VkImportSemaphoreWin32HandleInfoKHR::flags` or `VkImportSemaphoreFdInfoKHR::flags`. Bits which can be set include:

```c
typedef enum VkSemaphoreImportFlagBits {
    VK_SEMAPHORE_IMPORT_TEMPORARY_BIT = 0x00000001,
    VK_SEMAPHORE_IMPORT_TEMPORARY_BIT_KHR = VK_SEMAPHORE_IMPORT_TEMPORARY_BIT,
} VkSemaphoreImportFlagBits;
```

or the equivalent

```c
typedef VkSemaphoreImportFlagBits VkSemaphoreImportFlagBitsKHR;
```

These bits have the following meanings:

- **VK_SEMAPHORE_IMPORT_TEMPORARY_BIT** specifies that the semaphore payload will be imported only temporarily, as described in Importing Semaphore Payloads, regardless of the permanence of **handleType**.

```c
typedef VkFlags VkSemaphoreImportFlags;
```

or the equivalent

```c
typedef VkSemaphoreImportFlags VkSemaphoreImportFlagsKHR;
```

`VkSemaphoreImportFlags` is a bitmask type for setting a mask of zero or more `VkSemaphoreImportFlagBits`. 

---

216 | Chapter 6. Synchronization and Cache Control
6.5. Events

Events are a synchronization primitive that can be used to insert a fine-grained dependency between commands submitted to the same queue, or between the host and a queue. Events must not be used to insert a dependency between commands submitted to different queues. Events have two states - signaled and unsignaled. An application can signal or unsignal an event either on the host or on the device. A device can be made to wait for an event to become signaled before executing further operations. No command exists to wait for an event to become signaled on the host, but the current state of an event can be queried.

Events are represented by VkEvent handles:

```
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkEvent)
```

To create an event, call:

```
VkResult vkCreateEvent(
    VkDevice                                    device,
    const VkEventCreateInfo*                    pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkEvent*                                    pEvent);
```

- **device** is the logical device that creates the event.
- **pCreateInfo** is a pointer to a VkEventCreateInfo structure containing information about how the event is to be created.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pEvent** is a pointer to a handle in which the resulting event object is returned.

When created, the event object is in the unsignaled state.

**Valid Usage (Implicit)**

- **device** must be a valid VkDevice handle
- **pCreateInfo** must be a valid pointer to a valid VkEventCreateInfo structure
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid VkAllocationCallbacks structure
- **pEvent** must be a valid pointer to a VkEvent handle
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

The `VkEventCreateInfo` structure is defined as:

```c
typedef struct VkEventCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkEventCreateFlags flags;
} VkEventCreateInfo;
```

• `sType` is the type of this structure.
• `pNext` is NULL or a pointer to an extension-specific structure.
• `flags` is reserved for future use.

Valid Usage (Implicit)

• `sType` must be `VK_STRUCTURE_TYPE_EVENT_CREATE_INFO`
• `pNext` must be NULL
• `flags` must be 0

```c
typedef VkFlags VkEventCreateFlags;
```

`VkEventCreateFlags` is a bitmask type for setting a mask, but is currently reserved for future use.

To destroy an event, call:

```c
void vkDestroyEvent(
    VkDevice device,
    VkEvent event,
    const VkAllocationCallbacks* pAllocator);
```

• `device` is the logical device that destroys the event.
• `event` is the handle of the event to destroy.
• `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
Valid Usage

- All submitted commands that refer to `event` must have completed execution.
- If `VkAllocationCallbacks` were provided when `event` was created, a compatible set of callbacks must be provided here.
- If no `VkAllocationCallbacks` were provided when `event` was created, `pAllocator` must be `NULL`.

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle.
- If `event` is not `VK_NULL_HANDLE`, `event` must be a valid `VkEvent` handle.
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure.
- If `event` is a valid handle, it must have been created, allocated, or retrieved from `device`.

Host Synchronization

- Host access to `event` must be externally synchronized.

To query the state of an event from the host, call:

```cpp
VkResult vkGetEventStatus(
    VkDevice device, 
    VkEvent event);
```

- `device` is the logical device that owns the event.
- `event` is the handle of the event to query.

Upon success, `vkGetEventStatus` returns the state of the event object with the following return codes:

<table>
<thead>
<tr>
<th>Status</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>VK_EVENT_SET</td>
<td>The event specified by <code>event</code> is signaled.</td>
</tr>
<tr>
<td>VK_EVENT_RESET</td>
<td>The event specified by <code>event</code> is unsignaled.</td>
</tr>
</tbody>
</table>

If a `vkCmdSetEvent` or `vkCmdResetEvent` command is in a command buffer that is in the pending state, then the value returned by this command may immediately be out of date.
The state of an event can be updated by the host. The state of the event is immediately changed, and subsequent calls to `vkGetEventStatus` will return the new state. If an event is already in the requested state, then updating it to the same state has no effect.

### Valid Usage (Implicit)
- **device** must be a valid `VkDevice` handle
- **event** must be a valid `VkEvent` handle
- **event** must have been created, allocated, or retrieved from `device`

### Return Codes

**Success**
- `VK_EVENT_SET`
- `VK_EVENT_RESET`

**Failure**
- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`
- `VK_ERROR_DEVICE_LOST`

To set the state of an event to signaled from the host, call:

```c
VkResult vkSetEvent(
    VkDevice device,
    VkEvent event);
```

- **device** is the logical device that owns the event.
- **event** is the event to set.

When `vkSetEvent` is executed on the host, it defines an event signal operation which sets the event to the signaled state.

If **event** is already in the signaled state when `vkSetEvent` is executed, then `vkSetEvent` has no effect, and no event signal operation occurs.

### Valid Usage (Implicit)
- **device** must be a valid `VkDevice` handle
- **event** must be a valid `VkEvent` handle
- **event** must have been created, allocated, or retrieved from `device`
Host Synchronization

- Host access to event must be externally synchronized

Return Codes

Success
- VK_SUCCESS

Failure
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

To set the state of an event to unsignaled from the host, call:

```c
VkResult vkResetEvent(
    VkDevice device,
    VkEvent event);
```

- `device` is the logical device that owns the event.
- `event` is the event to reset.

When `vkResetEvent` is executed on the host, it defines an event unsignal operation which resets the event to the unsignaled state.

If `event` is already in the unsignaled state when `vkResetEvent` is executed, then `vkResetEvent` has no effect, and no event unsignal operation occurs.

Valid Usage

- `event` must not be waited on by a `vkCmdWaitEvents` command that is currently executing

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `event` must be a valid `VkEvent` handle
- `event` must have been created, allocated, or retrieved from `device`
Host Synchronization

- Host access to event must be externally synchronized

Return Codes

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

The state of an event can also be updated on the device by commands inserted in command buffers.

To set the state of an event to signaled from a device, call:

```c
void vkCmdSetEvent(
    VkCommandBuffer commandBuffer,
    VkEvent event,
    VkPipelineStageFlags stageMask);
```

- `commandBuffer` is the command buffer into which the command is recorded.
- `event` is the event that will be signaled.
- `stageMask` specifies the source stage mask used to determine when the `event` is signaled.

When `vkCmdSetEvent` is submitted to a queue, it defines an execution dependency on commands that were submitted before it, and defines an event signal operation which sets the event to the signaled state.

The first synchronization scope includes all commands that occur earlier in submission order. The synchronization scope is limited to operations on the pipeline stages determined by the source stage mask specified by `stageMask`.

The second synchronization scope includes only the event signal operation.

If `event` is already in the signaled state when `vkCmdSetEvent` is executed on the device, then `vkCmdSetEvent` has no effect, no event signal operation occurs, and no execution dependency is generated.
Valid Usage

- `stageMask` **must** not include `VK_PIPELINE_STAGE_HOST_BIT`
- If the **geometry shaders** feature is not enabled, `stageMask` **must** not contain `VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT`
- If the **tessellation shaders** feature is not enabled, `stageMask` **must** not contain `VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT` or `VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT`
- `commandBuffer`'s current device mask **must** include exactly one physical device
- If the **mesh shaders** feature is not enabled, `stageMask` **must** not contain `VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV`
- If the **task shaders** feature is not enabled, `stageMask` **must** not contain `VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV`

Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `event` **must** be a valid `VkEvent` handle
- `stageMask` **must** be a valid combination of `VkPipelineStageFlagBits` values
- `stageMask` **must** not be `0`
- `commandBuffer` **must** be in the **recording state**
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics, or compute operations
- This command **must** only be called outside of a render pass instance
- Both of `commandBuffer`, and `event` **must** have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized
To set the state of an event to unsignaled from a device, call:

```c
void vkCmdResetEvent(
    VkCommandBuffer commandBuffer,
    VkEvent event,
    VkPipelineStageFlags stageMask);
```

- `commandBuffer` is the command buffer into which the command is recorded.
- `event` is the event that will be unsignaled.
- `stageMask` is a bitmask of `VkPipelineStageFlagBits` specifying the source stage mask used to determine when the `event` is unsignaled.

When `vkCmdResetEvent` is submitted to a queue, it defines an execution dependency on commands that were submitted before it, and defines an event unsignal operation which resets the event to the unsignaled state.

The first synchronization scope includes all commands that occur earlier in submission order. The synchronization scope is limited to operations on the pipeline stages determined by the source stage mask specified by `stageMask`.

The second synchronization scope includes only the event unsignal operation.

If `event` is already in the unsignaled state when `vkCmdResetEvent` is executed on the device, then `vkCmdResetEvent` has no effect, no event unsignal operation occurs, and no execution dependency is generated.
Valid Usage

- **stageMask** **must not** include `VK_PIPELINE_STAGE_HOST_BIT`

- If the **geometry shaders** feature is not enabled, **stageMask** **must not** contain `VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT`

- If the **tessellation shaders** feature is not enabled, **stageMask** **must not** contain `VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT` or `VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT`

- When this command executes, **event** **must not** be waited on by a `vkCmdWaitEvents` command that is currently executing

- **commandBuffer**’s current device mask **must include** exactly one physical device

- If the **mesh shaders** feature is not enabled, **stageMask** **must not** contain `VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV`

- If the **task shaders** feature is not enabled, **stageMask** **must not** contain `VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV`

Valid Usage (Implicit)

- **commandBuffer** **must be** a valid `VkCommandBuffer` handle

- **event** **must be** a valid `VkEvent` handle

- **stageMask** **must be** a valid combination of `VkPipelineStageFlagBits` values

- **stageMask** **must not be** `0`

- **commandBuffer** **must be in** the **recording state**

- The `VkCommandPool` that **commandBuffer** **was allocated from** **must support** graphics, or compute operations

- This command **must only** be called outside of a render pass instance

- Both of **commandBuffer**, and **event** **must have** been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to **commandBuffer** **must be** externally synchronized

- Host access to the `VkCommandPool` that **commandBuffer** **was allocated from** **must be** externally synchronized
null
logically earlier than or equal to the logically latest pipeline stage in `srcStageMask`. Event signal operations performed by `vkSetEvent` are only included in the first synchronization scope if `VK_PIPELINE_STAGE_HOST_BIT` is included in `srcStageMask`.

The second synchronization scope includes all commands that occur later in submission order. The second synchronization scope is limited to operations on the pipeline stages determined by the destination stage mask specified by `dstStageMask`.

The first access scope is limited to access in the pipeline stages determined by the source stage mask specified by `srcStageMask`. Within that, the first access scope only includes the first access scopes defined by elements of the `pMemoryBarriers`, `pBufferMemoryBarriers` and `pImageMemoryBarriers` arrays, which each define a set of memory barriers. If no memory barriers are specified, then the first access scope includes no accesses.

The second access scope is limited to access in the pipeline stages determined by the destination stage mask specified by `dstStageMask`. Within that, the second access scope only includes the second access scopes defined by elements of the `pMemoryBarriers`, `pBufferMemoryBarriers` and `pImageMemoryBarriers` arrays, which each define a set of memory barriers. If no memory barriers are specified, then the second access scope includes no accesses.

Note

`vkCmdWaitEvents` is used with `vkCmdSetEvent` to define a memory dependency between two sets of action commands, roughly in the same way as pipeline barriers, but split into two commands such that work between the two may execute unhindered.

Unlike `vkCmdPipelineBarrier`, a queue family ownership transfer cannot be performed using `vkCmdWaitEvents`.

Note

Applications should be careful to avoid race conditions when using events. There is no direct ordering guarantee between a `vkCmdResetEvent` command and a `vkCmdWaitEvents` command submitted after it, so some other execution dependency must be included between these commands (e.g. a semaphore).
Valid Usage

- **srcStageMask** must be the bitwise OR of the **stageMask** parameter used in previous calls to `vkCmdSetEvent` with any of the members of **pEvents** and **VK_PIPELINE_STAGE_HOST_BIT** if any of the members of **pEvents** was set using `vkSetEvent`.

- If the **geometry shaders** feature is not enabled, **srcStageMask** must not contain **VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT**.

- If the **geometry shaders** feature is not enabled, **dstStageMask** must not contain **VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT**.

- If the **tessellation shaders** feature is not enabled, **srcStageMask** must not contain **VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT** or **VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT**.

- If the **tessellation shaders** feature is not enabled, **dstStageMask** must not contain **VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT** or **VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT**.

- If **pEvents** includes one or more events that will be signaled by `vkSetEvent` after commandBuffer has been submitted to a queue, then `vkCmdWaitEvents` must not be called inside a render pass instance.

- Any pipeline stage included in **srcStageMask** or **dstStageMask** must be supported by the capabilities of the queue family specified by the **queueFamilyIndex** member of the **VkCommandPoolCreateInfo** structure that was used to create the **VkCommandPool** that **commandBuffer** was allocated from, as specified in the table of supported pipeline stages.

- Each element of **pMemoryBarriers**, **pBufferMemoryBarriers** or **pImageMemoryBarriers** must not have any access flag included in its **srcAccessMask** member if that bit is not supported by any of the pipeline stages in **srcStageMask**, as specified in the table of supported access types.

- Each element of **pMemoryBarriers**, **pBufferMemoryBarriers** or **pImageMemoryBarriers** must not have any access flag included in its **dstAccessMask** member if that bit is not supported by any of the pipeline stages in **dstStageMask**, as specified in the table of supported access types.

- The **srcQueueFamilyIndex** and **dstQueueFamilyIndex** members of any element of **pBufferMemoryBarriers** or **pImageMemoryBarriers** must be equal.

- **commandBuffer**'s current device mask must include exactly one physical device.

- If the **mesh shaders** feature is not enabled, **srcStageMask** must not contain **VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV**.

- If the **task shaders** feature is not enabled, **srcStageMask** must not contain **VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV**.

- If the **mesh shaders** feature is not enabled, **dstStageMask** must not contain **VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV**.

- If the **task shaders** feature is not enabled, **dstStageMask** must not contain **VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV**.

- The **srcAccessMask** member of each element of **pMemoryBarriers** must only include access flags that are supported by one or more of the pipeline stages in **srcStageMask**, as specified in the table of supported access types.
• The `dstAccessMask` member of each element of `pMemoryBarriers` must only include access flags that are supported by one or more of the pipeline stages in `dstStageMask`, as specified in the table of supported access types.

• The `srcAccessMask` member of each element of `pBufferMemoryBarriers` must only include access flags that are supported by one or more of the pipeline stages in `srcStageMask`, as specified in the table of supported access types.

• The `dstAccessMask` member of each element of `pBufferMemoryBarriers` must only include access flags that are supported by one or more of the pipeline stages in `dstStageMask`, as specified in the table of supported access types.

• The `srcAccessMask` member of each element of `pImageMemoryBarriers` must only include access flags that are supported by one or more of the pipeline stages in `srcStageMask`, as specified in the table of supported access types.

• The `dstAccessMask` member of any element of `pImageMemoryBarriers` must only include access flags that are supported by one or more of the pipeline stages in `dstStageMask`, as specified in the table of supported access types.

Valid Usage (Implicit)

• `commandBuffer` must be a valid `VkCommandBuffer` handle.

• `pEvents` must be a valid pointer to an array of `eventCount` valid `VkEvent` handles.

• `srcStageMask` must be a valid combination of `VkPipelineStageFlagBits` values.

• `srcStageMask` must not be 0.

• `dstStageMask` must be a valid combination of `VkPipelineStageFlagBits` values.

• `dstStageMask` must not be 0.

• If `memoryBarrierCount` is not 0, `pMemoryBarriers` must be a valid pointer to an array of `memoryBarrierCount` valid `VkMemoryBarrier` structures.

• If `bufferMemoryBarrierCount` is not 0, `pBufferMemoryBarriers` must be a valid pointer to an array of `bufferMemoryBarrierCount` valid `VkBufferMemoryBarrier` structures.

• If `imageMemoryBarrierCount` is not 0, `pImageMemoryBarriers` must be a valid pointer to an array of `imageMemoryBarrierCount` valid `VkImageMemoryBarrier` structures.

• `commandBuffer` must be in the recording state.

• The `VkCommandPool` that `commandBuffer` was allocated from must support graphics, or compute operations.

• `eventCount` must be greater than 0.

• Both of `commandBuffer`, and the elements of `pEvents` must have been created, allocated, or retrieved from the same `VkDevice`.
Host Synchronization

- Host access to `commandBuffer` must be externally synchronized.
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized.

6.6. Pipeline Barriers

`vkCmdPipelineBarrier` is a synchronization command that inserts a dependency between commands submitted to the same queue, or between commands in the same subpass.

To record a pipeline barrier, call:

```c
void vkCmdPipelineBarrier(
    VkCommandBuffer     commandBuffer,
    VkPipelineStageFlags srcStageMask,     
    VkPipelineStageFlags dstStageMask,     
    VkDependencyFlags   dependencyFlags,   
    uint32_t            memoryBarrierCount, 
    const VkMemoryBarrier* pMemoryBarriers,
    uint32_t            bufferMemoryBarrierCount, 
    const VkBufferMemoryBarrier* pBufferMemoryBarriers,
    uint32_t            imageMemoryBarrierCount, 
    const VkImageMemoryBarrier* pImageMemoryBarriers);
```

- `commandBuffer` is the command buffer into which the command is recorded.
- `srcStageMask` is a bitmask of `VkPipelineStageFlagBits` specifying the source stage mask.
- `dstStageMask` is a bitmask of `VkPipelineStageFlagBits` specifying the destination stage mask.
- `dependencyFlags` is a bitmask of `VkDependencyFlagBits` specifying how execution and memory dependencies are formed.
- `memoryBarrierCount` is the length of the `pMemoryBarriers` array.
- `pMemoryBarriers` is a pointer to an array of `VkMemoryBarrier` structures.
- `bufferMemoryBarrierCount` is the length of the `pBufferMemoryBarriers` array.
- `pBufferMemoryBarriers` is a pointer to an array of `VkBufferMemoryBarrier` structures.
• `imageMemoryBarrierCount` is the length of the `pImageMemoryBarriers` array.

• `pImageMemoryBarriers` is a pointer to an array of `VkImageMemoryBarrier` structures.

When `vkCmdPipelineBarrier` is submitted to a queue, it defines a memory dependency between commands that were submitted before it, and those submitted after it.

If `vkCmdPipelineBarrier` was recorded outside a render pass instance, the first synchronization scope includes all commands that occur earlier in submission order. If `vkCmdPipelineBarrier` was recorded inside a render pass instance, the first synchronization scope includes only commands that occur earlier in submission order within the same subpass. In either case, the first synchronization scope is limited to operations on the pipeline stages determined by the source stage mask specified by `srcStageMask`.

If `vkCmdPipelineBarrier` was recorded outside a render pass instance, the second synchronization scope includes all commands that occur later in submission order. If `vkCmdPipelineBarrier` was recorded inside a render pass instance, the second synchronization scope includes only commands that occur later in submission order within the same subpass. In either case, the second synchronization scope is limited to operations on the pipeline stages determined by the destination stage mask specified by `dstStageMask`.

The first access scope is limited to access in the pipeline stages determined by the source stage mask specified by `srcStageMask`. Within that, the first access scope only includes the first access scopes defined by elements of the `pMemoryBarriers`, `pBufferMemoryBarriers` and `pImageMemoryBarriers` arrays, which each define a set of memory barriers. If no memory barriers are specified, then the first access scope includes no accesses.

The second access scope is limited to access in the pipeline stages determined by the destination stage mask specified by `dstStageMask`. Within that, the second access scope only includes the second access scopes defined by elements of the `pMemoryBarriers`, `pBufferMemoryBarriers` and `pImageMemoryBarriers` arrays, which each define a set of memory barriers. If no memory barriers are specified, then the second access scope includes no accesses.

If `dependencyFlags` includes `VK_DEPENDENCY_BY_REGION_BIT`, then any dependency between framebuffer-space pipeline stages is framebuffer-local - otherwise it is framebuffer-global.
Valid Usage

- If the geometry shaders feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT`.

- If the geometry shaders feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT`.

- If the tessellation shaders feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT` or `VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT`.

- If the tessellation shaders feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT` or `VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT`.

- If `vkCmdPipelineBarrier` is called within a render pass instance, the render pass must have been created with at least one `VkSubpassDependency` instance in `VkRenderPassCreateInfo::pDependencies` that expresses a dependency from the current subpass to itself, and for which `srcStageMask` contains a subset of the bit values in `VkSubpassDependency::srcStageMask`, `dstStageMask` contains a subset of the bit values in `VkSubpassDependency::dstStageMask`, `dependencyFlags` is equal to `VkSubpassDependency::dependencyFlags`, `srcAccessMask` member of each element of `pMemoryBarriers` and `pImageMemoryBarriers` contains a subset of the bit values in `VkSubpassDependency::srcAccessMask`, and `dstAccessMask` member of each element of `pMemoryBarriers` and `pImageMemoryBarriers` contains a subset of the bit values in `VkSubpassDependency::dstAccessMask`.

- If `vkCmdPipelineBarrier` is called within a render pass instance, `bufferMemoryBarrierCount` must be 0.

- If `vkCmdPipelineBarrier` is called within a render pass instance, the `image` member of any element of `pImageMemoryBarriers` must be equal to one of the elements of `pAttachments` that the current framebuffer was created with, that is also referred to by one of the elements of the `pColorAttachments`, `pResolveAttachments` or `pDepthStencilAttachment` members of the `VkSubpassDescription` instance or by the `pDepthStencilResolveAttachment` member of the `VkSubpassDescriptionDepthStencilResolve` structure that the current subpass was created with.

- If `vkCmdPipelineBarrier` is called within a render pass instance, the `oldLayout` and `newLayout` members of any element of `pImageMemoryBarriers` must be equal to the layout member of an element of the `pColorAttachments`, `pResolveAttachments` or `pDepthStencilAttachment` members of the `VkSubpassDescription` instance or by the `pDepthStencilResolveAttachment` member of the `VkSubpassDescriptionDepthStencilResolve` structure that the current subpass was created with, that refers to the same `image`.

- If `vkCmdPipelineBarrier` is called within a render pass instance, the `oldLayout` and `newLayout` members of an element of `pImageMemoryBarriers` must be equal.

- If `vkCmdPipelineBarrier` is called within a render pass instance, the `srcQueueFamilyIndex` and `dstQueueFamilyIndex` members of any element of `pImageMemoryBarriers` must be `VK_QUEUE_FAMILY_IGNORED`.

- Any pipeline stage included in `srcStageMask` or `dstStageMask` must be supported by the capabilities of the queue family specified by the `queueFamilyIndex` member of the `VkCommandPoolCreateInfo` structure that was used to create the `VkCommandPool` that
commandBuffer was allocated from, as specified in the table of supported pipeline stages

- If vkCmdPipelineBarrier is called outside of a render pass instance, dependencyFlags must not include VK_DEPENDENCY_VIEW_LOCAL_BIT

- If the mesh shaders feature is not enabled, srcStageMask must not contain VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV

- If the task shaders feature is not enabled, srcStageMask must not contain VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV

- If the mesh shaders feature is not enabled, dstStageMask must not contain VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV

- If the task shaders feature is not enabled, dstStageMask must not contain VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV

- The srcAccessMask member of each element of pMemoryBarriers must only include access flags that are supported by one or more of the pipeline stages in srcStageMask, as specified in the table of supported access types

- The dstAccessMask member of each element of pMemoryBarriers must only include access flags that are supported by one or more of the pipeline stages in dstStageMask, as specified in the table of supported access types

- For any element of pBufferMemoryBarriers, if its srcQueueFamilyIndex and dstQueueFamilyIndex members are equal, or if its srcQueueFamilyIndex is the queue family index that was used to create the command pool that commandBuffer was allocated from, then its srcAccessMask member must only contain access flags that are supported by one or more of the pipeline stages in srcStageMask, as specified in the table of supported access types

- For any element of pBufferMemoryBarriers, if its srcQueueFamilyIndex and dstQueueFamilyIndex members are equal, or if its dstQueueFamilyIndex is the queue family index that was used to create the command pool that commandBuffer was allocated from, then its dstAccessMask member must only contain access flags that are supported by one or more of the pipeline stages in dstStageMask, as specified in the table of supported access types

- For any element of pImageMemoryBarriers, if its srcQueueFamilyIndex and dstQueueFamilyIndex members are equal, or if its srcQueueFamilyIndex is the queue family index that was used to create the command pool that commandBuffer was allocated from, then its srcAccessMask member must only contain access flags that are supported by one or more of the pipeline stages in srcStageMask, as specified in the table of supported access types

- For any element of pImageMemoryBarriers, if its srcQueueFamilyIndex and dstQueueFamilyIndex members are equal, or if its dstQueueFamilyIndex is the queue family index that was used to create the command pool that commandBuffer was allocated from, then its dstAccessMask member must only contain access flags that are supported by one or more of the pipeline stages in dstStageMask, as specified in the table of supported access types
Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `srcStageMask` must be a valid combination of `VkPipelineStageFlagBits` values
- `srcStageMask` must not be 0
- `dstStageMask` must be a valid combination of `VkPipelineStageFlagBits` values
- `dstStageMask` must not be 0
- `dependencyFlags` must be a valid combination of `VkDependencyFlagBits` values
- If `memoryBarrierCount` is not 0, `pMemoryBarriers` must be a valid pointer to an array of `memoryBarrierCount` valid `VkMemoryBarrier` structures
- If `bufferMemoryBarrierCount` is not 0, ` pBufferMemoryBarriers` must be a valid pointer to an array of `bufferMemoryBarrierCount` valid `VkBufferMemoryBarrier` structures
- If `imageMemoryBarrierCount` is not 0, `pImageMemoryBarriers` must be a valid pointer to an array of `imageMemoryBarrierCount` valid `VkImageMemoryBarrier` structures
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support transfer, graphics, or compute operations

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Bits which can be set in `vkCmdPipelineBarrier::dependencyFlags`, specifying how execution and memory dependencies are formed, are:
typedef enum VkDependencyFlagBits {
    VK_DEPENDENCY_BY_REGION_BIT = 0x00000001,
    VK_DEPENDENCY_DEVICE_GROUP_BIT = 0x00000004,
    VK_DEPENDENCY_VIEW_LOCAL_BIT = 0x00000002,
    VK_DEPENDENCY_VIEW_LOCAL_BIT_KHR = VK_DEPENDENCY_VIEW_LOCAL_BIT,
    VK_DEPENDENCY_DEVICE_GROUP_BIT_KHR = VK_DEPENDENCY_DEVICE_GROUP_BIT,
} VkDependencyFlagBits;

- VK_DEPENDENCY_BY_REGION_BIT specifies that dependencies will be framebuffer-local.
- VK_DEPENDENCY_VIEW_LOCAL_BIT specifies that a subpass has more than one view.
- VK_DEPENDENCY_DEVICE_GROUP_BIT specifies that dependencies are non-device-local dependency.

typedef VkFlags VkDependencyFlags;

VkDependencyFlags is a bitmask type for setting a mask of zero or more VkDependencyFlagBits.

6.6.1. Subpass Self-dependency

If vkCmdPipelineBarrier is called inside a render pass instance, the following restrictions apply. For a given subpass to allow a pipeline barrier, the render pass must declare a self-dependency from that subpass to itself. That is, there must exist a VkSubpassDependency in the subpass dependency list for the render pass with srcSubpass and dstSubpass equal to that subpass index. More than one self-dependency can be declared for each subpass.

Self-dependencies must only include pipeline stage bits that are graphics stages. If any of the stages in srcStages are framebuffer-space stages, dstStages must only contain framebuffer-space stages. Additionally, srcStages must not contain VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT in a self-dependency.

If the source and destination stage masks both include framebuffer-space stages, then dependencyFlags must include VK_DEPENDENCY_BY_REGION_BIT. If the subpass has more than one view, then dependencyFlags must include VK_DEPENDENCY_VIEW_LOCAL_BIT.

A vkCmdPipelineBarrier command inside a render pass instance must be a subset of one of the self-dependencies of the subpass it is used in, meaning that the stage masks and access masks must each include only a subset of the bits of the corresponding mask in that self-dependency. If the self-dependency has VK_DEPENDENCY_BY_REGION_BIT or VK_DEPENDENCY_VIEW_LOCAL_BIT set, then so must the pipeline barrier. Pipeline barriers within a render pass instance can only be types VkMemoryBarrier or VkImageMemoryBarrier. If a VkImageMemoryBarrier is used, the image and image subresource range specified in the barrier must be a subset of one of the image views used by the framebuffer in the current subpass. Additionally, oldLayout must be equal to newLayout, and both the srcQueueFamilyIndex and dstQueueFamilyIndex must be VK_QUEUE_FAMILY_IGNORED.
6.7. Memory Barriers

Memory barriers are used to explicitly control access to buffer and image subresource ranges. Memory barriers are used to transfer ownership between queue families, change image layouts, and define availability and visibility operations. They explicitly define the access types and buffer and image subresource ranges that are included in the access scopes of a memory dependency that is created by a synchronization command that includes them.

6.7.1. Global Memory Barriers

Global memory barriers apply to memory accesses involving all memory objects that exist at the time of its execution.

The \textit{VkMemoryBarrier} structure is defined as:

\begin{verbatim}
typedef struct VkMemoryBarrier {
    VkStructureType    sType;
    const void*        pNext;
    VkAccessFlags      srcAccessMask;
    VkAccessFlags      dstAccessMask;
} VkMemoryBarrier;
\end{verbatim}

- \textit{sType} is the type of this structure.
- \textit{pNext} is NULL or a pointer to an extension-specific structure.
- \textit{srcAccessMask} is a bitmask of \textit{VkAccessFlagBits} specifying a source access mask.
- \textit{dstAccessMask} is a bitmask of \textit{VkAccessFlagBits} specifying a destination access mask.

The first access scope is limited to access types in the source access mask specified by \textit{srcAccessMask}.

The second access scope is limited to access types in the destination access mask specified by \textit{dstAccessMask}.

\begin{center}
\textbf{Valid Usage (Implicit)}
\end{center}

- \textit{sType} must be \texttt{VK_STRUCTURE_TYPE_MEMORY_BARRIER}
- \textit{pNext} must be \texttt{NULL}
- \textit{srcAccessMask} must be a valid combination of \textit{VkAccessFlagBits} values
- \textit{dstAccessMask} must be a valid combination of \textit{VkAccessFlagBits} values

6.7.2. Buffer Memory Barriers

Buffer memory barriers only apply to memory accesses involving a specific buffer range. That is, a memory dependency formed from a buffer memory barrier is scoped to access via the specified buffer range. Buffer memory barriers \texttt{can} also be used to define a queue family ownership transfer...
for the specified buffer range.

The **VkBufferMemoryBarrier** structure is defined as:

```c
typedef struct VkBufferMemoryBarrier {
    VkStructureType    sType;
    const void*        pNext;
    VkAccessFlags      srcAccessMask;
    VkAccessFlags      dstAccessMask;
    uint32_t           srcQueueFamilyIndex;
    uint32_t           dstQueueFamilyIndex;
    VkBuffer           buffer;
    VkDeviceSize       offset;
    VkDeviceSize       size;
} VkBufferMemoryBarrier;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **srcAccessMask** is a bitmask of **VkAccessFlagBits** specifying a source access mask.
- **dstAccessMask** is a bitmask of **VkAccessFlagBits** specifying a destination access mask.
- **srcQueueFamilyIndex** is the source queue family for a queue family ownership transfer.
- **dstQueueFamilyIndex** is the destination queue family for a queue family ownership transfer.
- **buffer** is a handle to the buffer whose backing memory is affected by the barrier.
- **offset** is an offset in bytes into the backing memory for **buffer**; this is relative to the base offset as bound to the buffer (see **vkBindBufferMemory**).
- **size** is a size in bytes of the affected area of backing memory for **buffer**, or **VK_WHOLE_SIZE** to use the range from **offset** to the end of the buffer.

The first access scope is limited to access to memory through the specified buffer range, via access types in the source access mask specified by **srcAccessMask**. If **srcAccessMask** includes **VK_ACCESS_HOST_WRITE_BIT**, memory writes performed by that access type are also made visible, as that access type is not performed through a resource.

The second access scope is limited to access to memory through the specified buffer range, via access types in the destination access mask specified by **dstAccessMask**. If **dstAccessMask** includes **VK_ACCESS_HOST_WRITE_BIT** or **VK_ACCESS_HOST_READ_BIT**, available memory writes are also made visible to accesses of those types, as those access types are not performed through a resource.

If **srcQueueFamilyIndex** is not equal to **dstQueueFamilyIndex**, and **srcQueueFamilyIndex** is equal to the current queue family, then the memory barrier defines a queue family release operation for the specified buffer range, and the second access scope includes no access, as if **dstAccessMask** was 0.

If **dstQueueFamilyIndex** is not equal to **srcQueueFamilyIndex**, and **dstQueueFamilyIndex** is equal to the current queue family, then the memory barrier defines a queue family acquire operation for the specified buffer range, and the first access scope includes no access, as if **srcAccessMask** was 0.
Valid Usage

• **offset** **must** be less than the size of **buffer**
• If **size** is not equal to **VK_WHOLE_SIZE**, **size** **must** be greater than 0
• If **size** is not equal to **VK_WHOLE_SIZE**, **size** **must** be less than or equal to than the size of **buffer** minus offset
• If **buffer** was created with a sharing mode of **VK_SHARING_MODE_CONCURRENT**, at least one of **srcQueueFamilyIndex** and **dstQueueFamilyIndex** **must** be **VK_QUEUE_FAMILY_IGNORED**
• If **buffer** was created with a sharing mode of **VK_SHARING_MODE_CONCURRENT**, and one of **srcQueueFamilyIndex** and **dstQueueFamilyIndex** is **VK_QUEUE_FAMILY_IGNORED**, the other **must** be **VK_QUEUE_FAMILY_IGNORED** or a special queue family reserved for external memory ownership transfers, as described in Queue Family Ownership Transfer
• If **buffer** was created with a sharing mode of **VK_SHARING_MODE_EXCLUSIVE** and **srcQueueFamilyIndex** is **VK_QUEUE_FAMILY_IGNORED**, **dstQueueFamilyIndex** **must** also be **VK_QUEUE_FAMILY_IGNORED**
• If **buffer** was created with a sharing mode of **VK_SHARING_MODE_EXCLUSIVE** and **srcQueueFamilyIndex** is not **VK_QUEUE_FAMILY_IGNORED**, it **must** be a valid queue family or a special queue family reserved for external memory transfers, as described in Queue Family Ownership Transfer
• If **buffer** was created with a sharing mode of **VK_SHARING_MODE_EXCLUSIVE** and **dstQueueFamilyIndex** is not **VK_QUEUE_FAMILY_IGNORED**, it **must** be a valid queue family or a special queue family reserved for external memory transfers, as described in Queue Family Ownership Transfer
• If **buffer** was created with a sharing mode of **VK_SHARING_MODE_EXCLUSIVE**, and **srcQueueFamilyIndex** and **dstQueueFamilyIndex** are not **VK_QUEUE_FAMILY_IGNORED**, at least one of them **must** be the same as the family of the queue that will execute this barrier
• If **buffer** is non-sparse then it **must** be bound completely and contiguously to a single **VkDeviceMemory** object

Valid Usage (Implicit)

• **sType** **must** be **VK_STRUCTURE_TYPE_BUFFER_MEMORY_BARRIER**
• **pNext** **must** be **NULL**
• **buffer** **must** be a valid **VkBuffer** handle

6.7.3. Image Memory Barriers

Image memory barriers only apply to memory accesses involving a specific image subresource range. That is, a memory dependency formed from an image memory barrier is scoped to access via the specified image subresource range. Image memory barriers can also be used to define image layout transitions or a queue family ownership transfer for the specified image subresource
The `VkImageMemoryBarrier` structure is defined as:

```c
typedef struct VkImageMemoryBarrier {
    VkStructureType sType;
    const void* pNext;
    VkAccessFlags srcAccessMask;
    VkAccessFlags dstAccessMask;
    VkImageLayout oldLayout;
    VkImageLayout newLayout;
    uint32_t srcQueueFamilyIndex;
    uint32_t dstQueueFamilyIndex;
    VkImage image;
    VkImageSubresourceRange subresourceRange;
} VkImageMemoryBarrier;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `srcAccessMask` is a bitmask of `VkAccessFlagBits` specifying a source access mask.
- `dstAccessMask` is a bitmask of `VkAccessFlagBits` specifying a destination access mask.
- `oldLayout` is the old layout in an image layout transition.
- `newLayout` is the new layout in an image layout transition.
- `srcQueueFamilyIndex` is the source queue family for a queue family ownership transfer.
- `dstQueueFamilyIndex` is the destination queue family for a queue family ownership transfer.
- `image` is a handle to the image affected by this barrier.
- `subresourceRange` describes the image subresource range within `image` that is affected by this barrier.

The first access scope is limited to access to memory through the specified image subresource range, via access types in the source access mask specified by `srcAccessMask`. If `srcAccessMask` includes `VK_ACCESS_HOST_WRITE_BIT`, memory writes performed by that access type are also made visible, as that access type is not performed through a resource.

The second access scope is limited to access to memory through the specified image subresource range, via access types in the destination access mask specified by `dstAccessMask`. If `dstAccessMask` includes `VK_ACCESS_HOST_WRITE_BIT` or `VK_ACCESS_HOST_READ_BIT`, available memory writes are also made visible to accesses of those types, as those access types are not performed through a resource.

If `srcQueueFamilyIndex` is not equal to `dstQueueFamilyIndex`, and `srcQueueFamilyIndex` is equal to the current queue family, then the memory barrier defines a queue family release operation for the specified image subresource range, and the second access scope includes no access, as if `dstAccessMask` was `0`.

If `dstQueueFamilyIndex` is not equal to `srcQueueFamilyIndex`, and `dstQueueFamilyIndex` is equal to the
current queue family, then the memory barrier defines a **queue family acquire operation** for the specified image subresource range, and the first access scope includes no access, as if `srcAccessMask` was 0.

If `oldLayout` is not equal to `newLayout`, then the memory barrier defines an **image layout transition** for the specified image subresource range.

Layout transitions that are performed via image memory barriers execute in their entirety in **submission order**, relative to other image layout transitions submitted to the same queue, including those performed by **render passes**. In effect there is an implicit execution dependency from each such layout transition to all layout transitions previously submitted to the same queue.

The image layout of each image subresource of a depth/stencil image created with `VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT` is dependent on the last sample locations used to render to the image subresource as a depth/stencil attachment, thus when the image member of a `VkImageMemoryBarrier` is an image created with this flag the application can include a `VkSampleLocationsInfoEXT` structure in the `pNext` chain of `VkImageMemoryBarrier` to specify the sample locations to use during the image layout transition.

If the `VkSampleLocationsInfoEXT` structure included in the `pNext` chain of `VkImageMemoryBarrier` does not match the sample location state last used to render to the image subresource range specified by `subresourceRange` or if no `VkSampleLocationsInfoEXT` structure is included in the `pNext` chain of `VkImageMemoryBarrier`, then the contents of the given image subresource range becomes undefined as if `oldLayout` would equal `VK_IMAGE_LAYOUT_UNDEFINED`.

If `image` has a multi-planar format and the image is **disjoint**, then including `VK_IMAGE_ASPECT_COLOR_BIT` in the `aspectMask` member of `subresourceRange` is equivalent to including `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT`, and (for three-plane formats only) `VK_IMAGE_ASPECT_PLANE_2_BIT`. 

240 | Chapter 6. Synchronization and Cache Control
Valid Usage

- oldLayout must be VK_IMAGE_LAYOUT_UNDEFINED or the current layout of the image subresources affected by the barrier.

- newLayout must not be VK_IMAGE_LAYOUT_UNDEFINED or VK_IMAGE_LAYOUT_PREINITIALIZED.

- If image was created with a sharing mode of VK_SHARING_MODE_CONCURRENT, at least one of srcQueueFamilyIndex and dstQueueFamilyIndex must be VK_QUEUE_FAMILY_IGNORED.

- If image was created with a sharing mode of VK_SHARING_MODE_CONCURRENT, and one of srcQueueFamilyIndex and dstQueueFamilyIndex is VK_QUEUE_FAMILY_IGNORED, the other must be VK_QUEUE_FAMILY_IGNORED or a special queue family reserved for external memory transfers, as described in Queue Family Ownership Transfer.

- If image was created with a sharing mode of VK_SHARING_MODE_EXCLUSIVE and srcQueueFamilyIndex is VK_QUEUE_FAMILY_IGNORED, dstQueueFamilyIndex must also be VK_QUEUE_FAMILY_IGNORED.

- If image was created with a sharing mode of VK_SHARING_MODE_EXCLUSIVE and srcQueueFamilyIndex is not VK_QUEUE_FAMILY_IGNORED, it must be a valid queue family or a special queue family reserved for external memory transfers, as described in Queue Family Ownership Transfer.

- If image was created with a sharing mode of VK_SHARING_MODE_EXCLUSIVE and dstQueueFamilyIndex is not VK_QUEUE_FAMILY_IGNORED, it must be a valid queue family or a special queue family reserved for external memory transfers, as described in Queue Family Ownership Transfer.

- If image was created with a sharing mode of VK_SHARING_MODE_EXCLUSIVE, and srcQueueFamilyIndex and dstQueueFamilyIndex are not VK_QUEUE_FAMILY_IGNORED, at least one of them must be the same as the family of the queue that will execute this barrier.

- subresourceRange.baseMipLevel must be less than the mipLevels specified in VkImageCreateInfo when image was created.

- If subresourceRange.levelCount is not VK_REMAINING_MIP_LEVELS, subresourceRange.baseMipLevel + subresourceRange.levelCount must be less than or equal to the mipLevels specified in VkImageCreateInfo when image was created.

- subresourceRange.baseArrayLayer must be less than the arrayLayers specified in VkImageCreateInfo when image was created.

- If subresourceRange.layerCount is not VK_REMAINING_ARRAY_LAYERS, subresourceRange.baseArrayLayer + subresourceRange.layerCount must be less than or equal to the arrayLayers specified in VkImageCreateInfo when image was created.

- If image has a depth/stencil format with both depth and stencil and the separateDepthStencilLayouts feature is enabled, then the aspectMask member of subresourceRange must include either or both VK_IMAGE_ASPECT_DEPTH_BIT and VK_IMAGE_ASPECT_STENCIL_BIT.

- If image has a depth/stencil format with both depth and stencil and the separateDepthStencilLayouts feature is not enabled, then the aspectMask member of subresourceRange must include both VK_IMAGE_ASPECT_DEPTH_BIT and VK_IMAGE_ASPECT_STENCIL_BIT.
• If image has a color format and either the format is single-plane or the image is not disjoint then the aspectMask member of subresourceRange must only include VK_IMAGE_ASPECT_COLOR_BIT

• If image has a multi-planar format and the image is disjoint, then the aspectMask member of subresourceRange must include either at least one of VK_IMAGE_ASPECT_PLANE_0_BIT, VK_IMAGE_ASPECT_PLANE_1_BIT, and VK_IMAGE_ASPECT_PLANE_2_BIT; or must include VK_IMAGE_ASPECT_COLOR_BIT

• If image has a multi-planar format with only two planes, then the aspectMask member of subresourceRange must not include VK_IMAGE_ASPECT_PLANE_2_BIT

• If either oldLayout or newLayout is VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL then image must have been created with VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT set

• If either oldLayout or newLayout is VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL then image must have been created with VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT set

• If either oldLayout or newLayout is VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL then image must have been created with VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT set

• If either oldLayout or newLayout is VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL then image must have been created with VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT set

• If either oldLayout or newLayout is VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL then image must have been created with VK_IMAGE_USAGE_SAMPLED_BIT or VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT set

• If either oldLayout or newLayout is VK_IMAGE_LAYOUT_TRANSFER_SRC_OPTIMAL then image must have been created with VK_IMAGE_USAGE_TRANSFER_SRC_BIT set

• If either oldLayout or newLayout is VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL then image must have been created with VK_IMAGE_USAGE_TRANSFER_DST_BIT set

• If image is non-sparse then it must be bound completely and contiguously to a single VkDeviceMemory object

• If either oldLayout or newLayout is VK_IMAGE_LAYOUT_SHADING_RATE_OPTIMAL_NV then image must have been created with VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV set
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_IMAGE_MEMORY_BARRIER`
- **pNext** must be `NULL` or a pointer to a valid instance of `VkSampleLocationsInfoEXT`
- The **sType** value of each struct in the **pNext** chain must be unique
- **oldLayout** must be a valid `VkImageLayout` value
- **newLayout** must be a valid `VkImageLayout` value
- **image** must be a valid `VkImage` handle
- **subresourceRange** must be a valid `VkImageSubresourceRange` structure

6.7.4. Queue Family Ownership Transfer

Resources created with a `VkSharingMode` of `VK_SHARING_MODE_EXCLUSIVE` must have their ownership explicitly transferred from one queue family to another in order to access their content in a well-defined manner on a queue in a different queue family. Resources shared with external APIs or instances using external memory must also explicitly manage ownership transfers between local and external queues (or equivalent constructs in external APIs) regardless of the `VkSharingMode` specified when creating them. The special queue family index `VK_QUEUE_FAMILY_EXTERNAL` represents any queue external to the resource’s current Vulkan instance, as long as the queue uses the same underlying physical device or device group and uses the same driver version as the resource’s `VkDevice`, as indicated by `VkPhysicalDeviceIDProperties::deviceUUID` and `VkPhysicalDeviceIDProperties::driverUUID`. The special queue family index `VK_QUEUE_FAMILY_FOREIGN_EXT` represents any queue external to the resource’s current Vulkan instance, regardless of the queue’s underlying physical device or driver version. This includes, for example, queues for fixed-function image processing devices, media codec devices, and display devices, as well as all queues that use the same underlying physical device (or device group) and driver version as the resource’s `VkDevice`. If memory dependencies are correctly expressed between uses of such a resource between two queues in different families, but no ownership transfer is defined, the contents of that resource are undefined for any read accesses performed by the second queue family.

**Note**

If an application does not need the contents of a resource to remain valid when transferring from one queue family to another, then the ownership transfer **should** be skipped.

**Note**

Applications should expect transfers to/from `VK_QUEUE_FAMILY_FOREIGN_EXT` to be more expensive than transfers to/from `VK_QUEUE_FAMILY_EXTERNAL_KHR`.

A queue family ownership transfer consists of two distinct parts:

1. Release exclusive ownership from the source queue family
2. Acquire exclusive ownership for the destination queue family

An application **must** ensure that these operations occur in the correct order by defining an execution dependency between them, e.g. using a semaphore.

A *release operation* is used to release exclusive ownership of a range of a buffer or image subresource range. A release operation is defined by executing a buffer memory barrier (for a buffer range) or an image memory barrier (for an image subresource range) using `vkCmdPipelineBarrier`, on a queue from the source queue family. The `srcQueueFamilyIndex` parameter of the barrier **must** be set to the source queue family index, and the `dstQueueFamilyIndex` parameter to the destination queue family index. `dstAccessMask` is ignored for such a barrier, such that no visibility operation is executed - the value of this mask does not affect the validity of the barrier. The release operation happens-after the availability operation, and happens-before operations specified in the second synchronization scope of the calling command.

An *acquire operation* is used to acquire exclusive ownership of a range of a buffer or image subresource range. An acquire operation is defined by executing a buffer memory barrier (for a buffer range) or an image memory barrier (for an image subresource range) using `vkCmdPipelineBarrier`, on a queue from the destination queue family. The buffer range or image subresource range specified in an acquire operation **must** match exactly that of a previous release operation. The `srcQueueFamilyIndex` parameter of the barrier **must** be set to the source queue family index, and the `dstQueueFamilyIndex` parameter to the destination queue family index. `srcAccessMask` is ignored for such a barrier, such that no availability operation is executed - the value of this mask does not affect the validity of the barrier. The acquire operation happens-after operations in the first synchronization scope of the calling command, and happens-before the visibility operation.

**Note**

Whilst it is not invalid to provide destination or source access masks for memory barriers used for release or acquire operations, respectively, they have no practical effect. Access after a release operation has undefined results, and so visibility for those accesses has no practical effect. Similarly, write access before an acquire operation will produce undefined results for future access, so availability of those writes has no practical use. In an earlier version of the specification, these were required to match on both sides - but this was subsequently relaxed. These masks **should** be set to 0.

If the transfer is via an image memory barrier, and an *image layout transition* is desired, then the values of `oldLayout` and `newLayout` in the *release operation*’s memory barrier **must** be equal to values of `oldLayout` and `newLayout` in the *acquire operation*’s memory barrier. Although the image layout transition is submitted twice, it will only be executed once. A layout transition specified in this way happens-after the *release operation* and happens-before the *acquire operation*.

If the values of `srcQueueFamilyIndex` and `dstQueueFamilyIndex` are equal, no ownership transfer is performed, and the barrier operates as if they were both set to `VK_QUEUE_FAMILY_IGNORED`.

Queue family ownership transfers **may** perform read and write accesses on all memory bound to the image subresource or buffer range, so applications **must** ensure that all memory writes have been made available before a queue family ownership transfer is executed. Available memory is automatically made visible to queue family release and acquire operations, and writes performed
by those operations are automatically made available.

Once a queue family has acquired ownership of a buffer range or image subresource range of a `VK_SHARING_MODE_EXCLUSIVE` resource, its contents are undefined to other queue families unless ownership is transferred. The contents of any portion of another resource which aliases memory that is bound to the transferred buffer or image subresource range are undefined after a release or acquire operation.

![Note]

Because events cannot be used directly for inter-queue synchronization, and because `vkCmdSetEvent` does not have the queue family index or memory barrier parameters needed by a release operation, the release and acquire operations of a queue family ownership transfer can only be performed using `vkCmdPipelineBarrier`.

### 6.8. Wait Idle Operations

To wait on the host for the completion of outstanding queue operations for a given queue, call:

```c
VkResult vkQueueWaitIdle(
    VkQueue queue);
```

- `queue` is the queue on which to wait.

`vkQueueWaitIdle` is equivalent to submitting a fence to a queue and waiting with an infinite timeout for that fence to signal.

**Valid Usage (Implicit)**

- `queue` must be a valid `VkQueue` handle

**Host Synchronization**

- Host access to `queue` must be externally synchronized

**Command Properties**

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>Any</td>
<td>-</td>
</tr>
</tbody>
</table>
## Return Codes

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERRORDEVICELOST

To wait on the host for the completion of outstanding queue operations for all queues on a given logical device, call:

```c
VkResult vkDeviceWaitIdle(
    VkDevice device);
```

- `device` is the logical device to idle.

`vkDeviceWaitIdle` is equivalent to calling `vkQueueWaitIdle` for all queues owned by `device`.

## Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle

## Host Synchronization

- Host access to all `VkQueue` objects created from `device` must be externally synchronized

## Return Codes

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_DEVICE_LOST
6.9. Host Write Ordering Guarantees

When batches of command buffers are submitted to a queue via `vkQueueSubmit`, it defines a memory dependency with prior host operations, and execution of command buffers submitted to the queue.

The first **synchronization scope** is defined by the host execution model, but includes execution of `vkQueueSubmit` on the host and anything that happened-before it.

The second **synchronization scope** includes all commands submitted in the same **queue submission**, and all commands that occur later in **submission order**.

The first **access scope** includes all host writes to mappable device memory that are available to the host memory domain.

The second **access scope** includes all memory access performed by the device.

6.10. Synchronization and Multiple Physical Devices

If a logical device includes more than one physical device, then fences, semaphores, and events all still have a single instance of the signaled state.

A fence becomes signaled when all physical devices complete the necessary queue operations.

Semaphore wait and signal operations all include a device index that is the sole physical device that performs the operation. These indices are provided in the `VkDeviceGroupSubmitInfo` and `VkDeviceGroupBindSparseInfo` structures. Semaphores are not exclusively owned by any physical device. For example, a semaphore can be signaled by one physical device and then waited on by a different physical device.

An event **can** only be waited on by the same physical device that signaled it (or the host).

6.11. Calibrated timestamps

In order to be able to correlate the time a particular operation took place at on timelines of different time domains (e.g. a device operation vs a host operation), Vulkan allows querying calibrated timestamps from multiple time domains.

To query calibrated timestamps from a set of time domains, call:

```c
VkResult vkGetCalibratedTimestampsEXT(  
    VkDevice device,  
    uint32_t timestampCount,  
    const VkCalibratedTimestampInfoEXT* pTimestampInfos,  
    uint64_t* pTimestamps,  
    uint64_t* pMaxDeviation);
```

- **device** is the logical device used to perform the query.
• `timestampCount` is the number of timestamps to query.

• `pTimestampInfos` is a pointer to an array of `timestampCount` `VkCalibratedTimestampInfoEXT` structures, describing the time domains the calibrated timestamps should be captured from.

• `pTimestamps` is a pointer to an array of `timestampCount` 64-bit unsigned integer values in which the requested calibrated timestamp values are returned.

• `pMaxDeviation` is a pointer to a 64-bit unsigned integer value in which the strictly positive maximum deviation, in nanoseconds, of the calibrated timestamp values is returned.

**Note**
The maximum deviation *may* vary between calls to `vkGetCalibratedTimestampsEXT` even for the same set of time domains due to implementation and platform specific reasons. It is the application’s responsibility to assess whether the returned maximum deviation makes the timestamp values suitable for any particular purpose and *can* choose to re-issue the timestamp calibration call pursuing a lower deviation value.

Calibrated timestamp values *can* be extrapolated to estimate future coinciding timestamp values, however, depending on the nature of the time domains and other properties of the platform extrapolating values over a sufficiently long period of time *may* no longer be accurate enough to fit any particular purpose so applications are expected to re-calibrate the timestamps on a regular basis.

**Valid Usage (Implicit)**

• `device` **must** be a valid `VkDevice` handle

• `pTimestampInfos` **must** be a valid pointer to an array of `timestampCount` valid `VkCalibratedTimestampInfoEXT` structures

• `pTimestamps` **must** be a valid pointer to an array of `timestampCount` `uint64_t` values

• `pMaxDeviation` **must** be a valid pointer to a `uint64_t` value

• `timestampCount` **must** be greater than 0

**Return Codes**

**Success**

• `VK_SUCCESS`

**Failure**

• `VK_ERROR_OUT_OF_HOST_MEMORY`

• `VK_ERROR_OUT_OF_DEVICE_MEMORY`

The `VkCalibratedTimestampInfoEXT` structure is defined as:

---

248 | Chapter 6. Synchronization and Cache Control
typedef struct VkCalibratedTimestampInfoEXT {
    VkStructureType  sType;
    const void*      pNext;
    VkTimeDomainEXT  timeDomain;
} VkCalibratedTimestampInfoEXT;

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **timeDomain** is a `VkTimeDomainEXT` value specifying the time domain from which the calibrated timestamp value should be returned.

### Valid Usage

- **timeDomain** must be one of the `VkTimeDomainEXT` values returned by `vkGetPhysicalDeviceCalibrateableTimeDomainsEXT`

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_CALIBRATED_TIMESTAMP_INFO_EXT`
- **pNext** must be `NULL`
- **timeDomain** must be a valid `VkTimeDomainEXT` value

The set of supported time domains consists of:

typedef enum VkTimeDomainEXT {
    VK_TIME_DOMAIN_DEVICE_EXT = 0,
    VK_TIME_DOMAIN_CLOCK_MONOTONIC_EXT = 1,
    VK_TIME_DOMAIN_CLOCK_MONOTONIC_RAW_EXT = 2,
    VK_TIME_DOMAIN_QUERY_PERFORMANCE_COUNTER_EXT = 3,
} VkTimeDomainEXT;

- **VK_TIME_DOMAIN_DEVICE_EXT** specifies the device time domain. Timestamp values in this time domain use the same units and are comparable with device timestamp values captured using `vkCmdWriteTimestamp` and are defined to be incrementing according to the `timestampPeriod` of the device.

- **VK_TIME_DOMAIN_CLOCK_MONOTONIC_EXT** specifies the CLOCK_MONOTONIC time domain available on POSIX platforms. Timestamp values in this time domain are in units of nanoseconds and are comparable with platform timestamp values captured using the POSIX `clock_gettime` API as computed by this example:
struct timespec tv;
clock_gettime(CLOCK_MONOTONIC, &tv);
return tv.tv_nsec + tv.tv_sec*1000000000ull;

• **VK_TIME_DOMAIN_CLOCK_MONOTONIC_RAW_EXT** specifies the CLOCK_MONOTONIC_RAW time domain available on POSIX platforms. Timestamp values in this time domain are in units of nanoseconds and are comparable with platform timestamp values captured using the POSIX clock_gettime API as computed by this example:

```c
struct timespec tv;
clock_gettime(CLOCK_MONOTONIC_RAW, &tv);
return tv.tv_nsec + tv.tv_sec*1000000000ull;
```

• **VK_TIME_DOMAIN_QUERY_PERFORMANCE_COUNTER_EXT** specifies the performance counter (QPC) time domain available on Windows. Timestamp values in this time domain are in the same units as those provided by the Windows QueryPerformanceCounter API and are comparable with platform timestamp values captured using that API as computed by this example:

```c
LARGE_INTEGER counter;
QueryPerformanceCounter(&counter);
return counter.QuadPart;
```
Chapter 7. Render Pass

A *render pass* represents a collection of attachments, subpasses, and dependencies between the subpasses, and describes how the attachments are used over the course of the subpasses. The use of a render pass in a command buffer is a *render pass instance*.

Render passes are represented by `VkRenderPass` handles:

```
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkRenderPass)
```

An *attachment description* describes the properties of an attachment including its format, sample count, and how its contents are treated at the beginning and end of each render pass instance.

A *subpass* represents a phase of rendering that reads and writes a subset of the attachments in a render pass. Rendering commands are recorded into a particular subpass of a render pass instance.

A *subpass description* describes the subset of attachments that is involved in the execution of a subpass. Each subpass can read from some attachments as *input attachments*, write to some as *color attachments* or *depth/stencil attachments*, perform *shader resolve operations* to *color attachments* or *depth/stencil attachments*, and perform *multisample resolve operations* to *resolve attachments*. A subpass description can also include a set of *preserve attachments*, which are attachments that are not read or written by the subpass but whose contents must be preserved throughout the subpass.

A subpass uses an attachment if the attachment is a color, depth/stencil, resolve, depth/stencil resolve, or input attachment for that subpass (as determined by the `pColorAttachments`, `pDepthStencilAttachment`, `pResolveAttachments`, `VkSubpassDescriptionDepthStencilResolve::pDepthStencilResolveAttachment`, and `pInputAttachments` members of `VkSubpassDescription`, respectively). A subpass does not use an attachment if that attachment is preserved by the subpass. The first use of an attachment is in the lowest numbered subpass that uses that attachment. Similarly, the last use of an attachment is in the highest numbered subpass that uses that attachment.

The subpasses in a render pass all render to the same dimensions, and fragments for pixel *(x,y,layer)* in one subpass can only read attachment contents written by previous subpasses at that same *(x,y,layer)* location.

**Note**

By describing a complete set of subpasses in advance, render passes provide the implementation an opportunity to optimize the storage and transfer of attachment data between subpasses.

In practice, this means that subpasses with a simple framebuffer-space dependency may be merged into a single tiled rendering pass, keeping the attachment data on-chip for the duration of a render pass instance. However, it is also quite common for a render pass to only contain a single subpass.
Subpass dependencies describe execution and memory dependencies between subpasses.

A subpass dependency chain is a sequence of subpass dependencies in a render pass, where the source subpass of each subpass dependency (after the first) equals the destination subpass of the previous dependency.

Execution of subpasses may overlap or execute out of order with regards to other subpasses, unless otherwise enforced by an execution dependency. Each subpass only respects submission order for commands recorded in the same subpass, and the vkCmdBeginRenderPass and vkCmdEndRenderPass commands that delimit the render pass - commands within other subpasses are not included. This affects most other implicit ordering guarantees.

A render pass describes the structure of subpasses and attachments independent of any specific image views for the attachments. The specific image views that will be used for the attachments, and their dimensions, are specified in VkFramebuffer objects. Framebuffers are created with respect to a specific render pass that the framebuffer is compatible with (see Render Pass Compatibility). Collectively, a render pass and a framebuffer define the complete render target state for one or more subpasses as well as the algorithmic dependencies between the subpasses.

The various pipeline stages of the drawing commands for a given subpass may execute concurrently and/or out of order, both within and across drawing commands, whilst still respecting pipeline order. However for a given (x,y,layer,sample) sample location, certain per-sample operations are performed in rasterization order.

### 7.1. Render Pass Creation

To create a render pass, call:

```c
VkResult vkCreateRenderPass(
    VkDevice device,
    const VkRenderPassCreateInfo* pCreateInfo,
    const VkAllocationCallbacks* pAllocator,
    VkRenderPass* pRenderPass);
```

- `device` is the logical device that creates the render pass.
- `pCreateInfo` is a pointer to a VkRenderPassCreateInfo structure describing the parameters of the render pass.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
- `pRenderPass` is a pointer to a VkRenderPass handle in which the resulting render pass object is returned.
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pCreateInfo** must be a valid pointer to a valid `VkRenderPassCreateInfo` structure
- If **pAllocator** is not `NULL`, **pAllocator** must be a valid pointer to a valid `VkAllocationCallbacks` structure
- **pRenderPass** must be a valid pointer to a `VkRenderPass` handle

Return Codes

Success
- **VK_SUCCESS**

Failure
- **VK_ERROR_OUT_OF_HOST_MEMORY**
- **VK_ERROR_OUT_OF_DEVICE_MEMORY**

The `VkRenderPassCreateInfo` structure is defined as:

```c
typedef struct VkRenderPassCreateInfo {
    VkStructureType                   sType;
    const void*                       pNext;
    VkRenderPassCreateFlags           flags;
    uint32_t                          attachmentCount;
    const VkAttachmentDescription*    pAttachments;
    uint32_t                          subpassCount;
    const VkSubpassDescription*       pSubpasses;
    uint32_t                          dependencyCount;
    const VkSubpassDependency*        pDependencies;
} VkRenderPassCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkRenderPassCreateFlagBits`
- **attachmentCount** is the number of attachments used by this render pass.
- **pAttachments** is a pointer to an array of `attachmentCount` `VkAttachmentDescription` structures describing the attachments used by the render pass.
- **subpassCount** is the number of subpasses to create.
- **pSubpasses** is a pointer to an array of `subpassCount` `VkSubpassDescription` structures describing each subpass.
- **dependencyCount** is the number of memory dependencies between pairs of subpasses.
• **pDependencies** is a pointer to an array of `dependencyCount` `VkSubpassDependency` structures describing dependencies between pairs of subpasses.

**Note**

Care should be taken to avoid a data race here; if any subpasses access attachments with overlapping memory locations, and one of those accesses is a write, a subpass dependency needs to be included between them.
Valid Usage

- If the attachment member of any element of pInputAttachments, pColorAttachments, pResolveAttachments or pDepthStencilAttachment, or any element of pResolveAttachments in any element of pSubpasses is not VK_ATTACHMENT_UNUSED, it must be less than attachmentCount.

- For any member of pAttachments with a loadOp equal to VK_ATTACHMENT_LOAD_OP_CLEAR, the first use of that attachment must not specify a layout equal to VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL or VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL.

- For any member of pAttachments with a stencilLoadOp equal to VK_ATTACHMENT_LOAD_OP_CLEAR, the first use of that attachment must not specify a layout equal to VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL or VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL.

- For any member of pAttachments with a loadOp equal to VK_ATTACHMENT_LOAD_OP_CLEAR, the first use of that attachment must not specify a layout equal to VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL.

- If the pNext chain includes a VkRenderPassInputAttachmentAspectCreateInfo structure, the subpass member of each element of its pAspectReferences member must be less than subpassCount.

- If the pNext chain includes a VkRenderPassInputAttachmentAspectCreateInfo structure, the inputAttachmentIndex member of each element of its pAspectReferences member must be less than the value of inputAttachmentCount in the member of pSubpasses identified by its subpass member.

- If the pNext chain includes a VkRenderPassInputAttachmentAspectCreateInfo structure, for any element of the pInputAttachments member of any element of pSubpasses where the attachment member is not VK_ATTACHMENT_UNUSED, the aspectMask member of the corresponding element of VkRenderPassInputAttachmentAspectCreateInfo::pAspectReferences must only include aspects that are present in images of the format specified by the element of pAttachments at attachment.

- If the pNext chain includes a VkRenderPassMultiviewCreateInfo structure, and its subpassCount member is not zero, that member must be equal to the value of subpassCount.

- If the pNext chain includes a VkRenderPassMultiviewCreateInfo structure, if its dependencyCount member is not zero, it must be equal to dependencyCount.

- If the pNext chain includes a VkRenderPassMultiviewCreateInfo structure, for each non-zero element of pViewOffsets, the srcSubpass and dstSubpass members of pDependencies at the same index must not be equal.

- If the pNext chain includes a VkRenderPassMultiviewCreateInfo structure, for any element of pDependencies with a dependencyFlags member that does not include VK_DEPENDENCY_VIEW_LOCAL_BIT, the corresponding element of the pViewOffsets member of that VkRenderPassMultiviewCreateInfo instance must be 0.
• If the `pNext` chain includes a `VkRenderPassMultiviewCreateInfo` structure, elements of its `pViewMasks` member must either all be 0, or all not be 0

• If the `pNext` chain includes a `VkRenderPassMultiviewCreateInfo` structure, and each element of its `pViewMasks` member is 0, the `dependencyFlags` member of each element of `pDependencies` must not include `VK_DEPENDENCY_VIEW_LOCAL_BIT`

• If the `pNext` chain includes a `VkRenderPassMultiviewCreateInfo` structure, and each element of its `pViewMasks` member is 0, `correlatedViewMaskCount` must be 0

• If the `pNext` chain includes a `VkRenderPassMultiviewCreateInfo` structure, each element of its `pViewMask` member must not have a bit set at an index greater than or equal to `VkPhysicalDeviceLimits::maxFramebufferLayers`

• For any element of `pDependencies`, if the `srcSubpass` is not `VK_SUBPASS_EXTERNAL`, all stage flags included in the `srcStageMask` member of that dependency must be a pipeline stage supported by the pipeline identified by the `pipelineBindPoint` member of the source subpass

• For any element of `pDependencies`, if the `dstSubpass` is not `VK_SUBPASS_EXTERNAL`, all stage flags included in the `dstStageMask` member of that dependency must be a pipeline stage supported by the pipeline identified by the `pipelineBindPoint` member of the destination subpass

• The `srcSubpass` member of each element of `pDependencies` must be less than `subpassCount`

• The `dstSubpass` member of each element of `pDependencies` must be less than `subpassCount`

Valid Usage (Implicit)

• `sType` must be `VK_STRUCTURE_TYPE_RENDER_PASS_CREATE_INFO`

• Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkRenderPassFragmentDensityMapCreateInfoEXT`, `VkRenderPassInputAttachmentAspectCreateInfo`, or `VkRenderPassMultiviewCreateInfo`

• The `sType` value of each struct in the `pNext` chain must be unique

• `flags` must be a valid combination of `VkRenderPassCreateFlagBits` values

• If `attachmentCount` is not 0, `pAttachments` must be a valid pointer to an array of `attachmentCount` valid `VkAttachmentDescription` structures

• `pSubpasses` must be a valid pointer to an array of `subpassCount` valid `VkSubpassDescription` structures

• If `dependencyCount` is not 0, `pDependencies` must be a valid pointer to an array of `dependencyCount` valid `VkSubpassDependency` structures

• `subpassCount` must be greater than 0

Bits which can be set in `VkRenderPassCreateInfo::flags` describing additional properties of the render pass are:
typedef enum VkRenderPassCreateFlagBits {
    VK_RENDER_PASS_CREATE_TRANSFORM_BIT_QCOM = 0x00000002,
} VkRenderPassCreateFlagBits;

- **VK_RENDER_PASS_CREATE_TRANSFORM_BIT_QCOM** specifies that the created renderpass is compatible with render pass transform.

If the `VkRenderPassCreateInfo::pNext` chain includes a `VkRenderPassMultiviewCreateInfo` structure, then that structure includes an array of view masks, view offsets, and correlation create masks for the render pass.

The `VkRenderPassMultiviewCreateInfo` structure is defined as:

```c
typedef struct VkRenderPassMultiviewCreateInfo {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           subpassCount;
    const uint32_t*    pViewMasks;
    uint32_t           dependencyCount;
    const int32_t*     pViewOffsets;
    uint32_t           correlationMaskCount;
    const uint32_t*    pCorrelationMasks;
} VkRenderPassMultiviewCreateInfo;
```

or the equivalent

```c
typedef VkRenderPassMultiviewCreateInfo VkRenderPassMultiviewCreateInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **subpassCount** is zero or the number of subpasses in the render pass.
- **pViewMasks** is a pointer to an array of `subpassCount` view masks, where each mask is a bitfield of view indices describing which views rendering is broadcast to in each subpass, when multiview is enabled. If `subpassCount` is zero, each view mask is treated as zero.
- **dependencyCount** is zero or the number of dependencies in the render pass.
- **pViewOffsets** is a pointer to an array of `dependencyCount` view offsets, one for each dependency. If `dependencyCount` is zero, each dependency’s view offset is treated as zero. Each view offset controls which views in the source subpass the views in the destination subpass depend on.
- **correlationMaskCount** is zero or the number of correlation masks.
- **pCorrelationMasks** is a pointer to an array of `correlationMaskCount` view masks indicating sets of views that **may** be more efficient to render concurrently.

When a subpass uses a non-zero view mask, **multiview** functionality is considered to be enabled. Multiview is all-or-nothing for a render pass - that is, either all subpasses **must** have a non-zero...
view mask (though some subpasses may have only one view) or all must be zero. Multiview causes all drawing and clear commands in the subpass to behave as if they were broadcast to each view, where a view is represented by one layer of the framebuffer attachments. All draws and clears are broadcast to each view index whose bit is set in the view mask. The view index is provided in the ViewIndex shader input variable, and color, depth/stencil, and input attachments all read/write the layer of the framebuffer corresponding to the view index.

If the view mask is zero for all subpasses, multiview is considered to be disabled and all drawing commands execute normally, without this additional broadcasting.

Some implementations may not support multiview in conjunction with geometry shaders or tessellation shaders.

When multiview is enabled, the VK_DEPENDENCY_VIEW_LOCAL_BIT bit in a dependency can be used to express a view-local dependency, meaning that each view in the destination subpass depends on a single view in the source subpass. Unlike pipeline barriers, a subpass dependency can potentially have a different view mask in the source subpass and the destination subpass. If the dependency is view-local, then each view (dstView) in the destination subpass depends on the view dstView + pViewOffsets[dependency] in the source subpass. If there is not such a view in the source subpass, then this dependency does not affect that view in the destination subpass. If the dependency is not view-local, then all views in the destination subpass depend on all views in the source subpass, and the view offset is ignored. A non-zero view offset is not allowed in a self-dependency.

The elements of pCorrelationMasks are a set of masks of views indicating that views in the same mask may exhibit spatial coherency between the views, making it more efficient to render them concurrently. Correlation masks must not have a functional effect on the results of the multiview rendering.

When multiview is enabled, at the beginning of each subpass all non-render pass state is undefined. In particular, each time vkCmdBeginRenderPass or vkCmdNextSubpass is called the graphics pipeline must be bound, any relevant descriptor sets or vertex/index buffers must be bound, and any relevant dynamic state or push constants must be set before they are used.

A multiview subpass can declare that its shaders will write per-view attributes for all views in a single invocation, by setting the VK_SUBPASS_DESCRIPTION_PER_VIEW_ATTRIBUTES_BIT_NVX bit in the subpass description. The only supported per-view attributes are position and viewport mask, and per-view position and viewport masks are written to output array variables decorated with PositionPerViewNV and ViewportMaskPerViewNV, respectively. If VK_NV_viewport_array2 is not supported and enabled, ViewportMaskPerViewNV must not be used. Values written to elements of PositionPerViewNV and ViewportMaskPerViewNV must not depend on the ViewIndex. The shader must also write to an output variable decorated with Position, and the value written to Position must equal the value written to PositionPerViewNV[ViewIndex]. Similarly, if ViewportMaskPerViewNV is written to then the shader must also write to an output variable decorated with ViewportMaskNV, and the value written to ViewportMaskNV must equal the value written to ViewportMaskPerViewNV[ViewIndex]. Implementations will either use values taken from Position and ViewportMaskNV and invoke the shader once for each view, or will use values taken from PositionPerViewNV and ViewportMaskPerViewNV and invoke the shader fewer times. The values written to Position and ViewportMaskNV must not depend on the values written to PositionPerViewNV and ViewportMaskPerViewNV, or vice versa (to allow compilers to eliminate the unused outputs). All
attributes that do not have \*PerViewNV counterparts must not depend on ViewIndex.

Per-view attributes are all-or-nothing for a subpass. That is, all pipelines compiled against a subpass that includes the VK_SUBPASS_DESCRIPTION_PER_VIEW_ATTRIBUTES_BIT_NVX bit must write per-view attributes to the \*PerViewNV[] shader outputs, in addition to the non-per-view (e.g. Position) outputs. Pipelines compiled against a subpass that does not include this bit must not include the \*PerViewNV[] outputs in their interfaces.

Valid Usage

- Each view index must not be set in more than one element of pCorrelationMasks

Valid Usage (Implicit)

- sType must be VK_STRUCTURE_TYPE_RENDER_PASS_MULTIVIEW_CREATE_INFO
- If subpassCount is not 0, pViewMasks must be a valid pointer to an array of subpassCount uint32_t values
- If dependencyCount is not 0, pViewOffsets must be a valid pointer to an array of dependencyCount int32_t values
- If correlationMaskCount is not 0, pCorrelationMasks must be a valid pointer to an array of correlationMaskCount uint32_t values

If the VkRenderPassCreateInfo::pNext chain includes a VkRenderPassFragmentDensityMapCreateInfoEXT structure, then that structure includes a fragment density map attachment for the render pass.

The VkRenderPassFragmentDensityMapCreateInfoEXT structure is defined as:

```c
typedef struct VkRenderPassFragmentDensityMapCreateInfoEXT {
    VkStructureType          sType;
    const void*              pNext;
    VkAttachmentReference    fragmentDensityMapAttachment;
} VkRenderPassFragmentDensityMapCreateInfoEXT;
```

- sType is the type of this structure.
- pNext is NULL or a pointer to an extension-specific structure.
- fragmentDensityMapAttachment is the fragment density map to use for the render pass.

The fragment density map attachment is read at an implementation-dependent time either by the host during vkCmdBeginRenderPass if the attachment’s image view was not created with flags containing VK_IMAGE_VIEW_CREATE_FRAGMENT_DENSITY_MAP_DYNAMIC_BIT_EXT, or by the device when drawing commands in the renderpass execute VK_PIPELINE_STAGE_FRAGMENT_DENSITY_PROCESS_BIT_EXT.

If this structure is not present, it is as if fragmentDensityMapAttachment was given as...
Valid Usage

- If `fragmentDensityMapAttachment` is not `VK_ATTACHMENT_UNUSED`, `fragmentDensityMapAttachment` must be less than `VkRenderPassCreateInfo::attachmentCount`
- If `fragmentDensityMapAttachment` is not `VK_ATTACHMENT_UNUSED`, `fragmentDensityMapAttachment` must not be an element of `VkSubpassDescription::pInputAttachments`, `VkSubpassDescription::pColorAttachments`, `VkSubpassDescription::pResolveAttachments`, `VkSubpassDescription::pDepthStencilAttachment`, or `VkSubpassDescription::pPreserveAttachments` for any subpass
- If `fragmentDensityMapAttachment` is not `VK_ATTACHMENT_UNUSED`, `layout` must be equal to `VK_IMAGE_LAYOUT_FRAGMENT_DENSITY_MAP_OPTIMAL_EXT`, or `VK_IMAGE_LAYOUT_GENERAL`
- If `fragmentDensityMapAttachment` is not `VK_ATTACHMENT_UNUSED`, `fragmentDensityMapAttachment` must reference an attachment with a `loadOp` equal to `VK_ATTACHMENT_LOAD_OP_LOAD` or `VK_ATTACHMENT_LOAD_OP_DONT_CARE`
- If `fragmentDensityMapAttachment` is not `VK_ATTACHMENT_UNUSED`, `fragmentDensityMapAttachment` must reference an attachment with a `storeOp` equal to `VK_ATTACHMENT_STORE_OP_DONT_CARE`

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_RENDER_PASS_FRAGMENT_DENSITY_MAP_CREATE_INFO_EXT`
- `fragmentDensityMapAttachment` must be a valid `VkAttachmentReference` structure

The `VkAttachmentDescription` structure is defined as:

```c
typedef struct VkAttachmentDescription {
    VkAttachmentDescriptionFlags flags;
    VkFormat format;
    VkSampleCountFlagBits samples;
    VkAttachmentLoadOp loadOp;
    VkAttachmentStoreOp storeOp;
    VkAttachmentLoadOp stencilLoadOp;
    VkAttachmentStoreOp stencilStoreOp;
    VkImageLayout initialLayout;
    VkImageLayout finalLayout;
} VkAttachmentDescription;
```

- `flags` is a bitmask of `VkAttachmentDescriptionFlagBits` specifying additional properties of the attachment.
- `format` is a `VkFormat` value specifying the format of the image view that will be used for the attachment.
- `samples` is the number of samples of the image as defined in `VkSampleCountFlagBits`.

260 | Chapter 7. Render Pass
• **loadOp** is a `VkAttachmentLoadOp` value specifying how the contents of color and depth components of the attachment are treated at the beginning of the subpass where it is first used.

• **storeOp** is a `VkAttachmentStoreOp` value specifying how the contents of color and depth components of the attachment are treated at the end of the subpass where it is last used.

• **stencilLoadOp** is a `VkAttachmentLoadOp` value specifying how the contents of stencil components of the attachment are treated at the beginning of the subpass where it is first used.

• **stencilStoreOp** is a `VkAttachmentStoreOp` value specifying how the contents of stencil components of the attachment are treated at the end of the last subpass where it is used.

• **initialLayout** is the layout the attachment image subresource will be in when a render pass instance begins.

• **finalLayout** is the layout the attachment image subresource will be transitioned to when a render pass instance ends.

If the attachment uses a color format, then `loadOp` and `storeOp` are used, and `stencilLoadOp` and `stencilStoreOp` are ignored. If the format has depth and/or stencil components, `loadOp` and `storeOp` apply only to the depth data, while `stencilLoadOp` and `stencilStoreOp` define how the stencil data is handled. `loadOp` and `stencilLoadOp` define the **load operations** that execute as part of the first subpass that uses the attachment. `storeOp` and `stencilStoreOp` define the **store operations** that execute as part of the last subpass that uses the attachment.

The load operation for each sample in an attachment happens-before any recorded command which accesses the sample in the first subpass where the attachment is used. Load operations for attachments with a depth/stencil format execute in the `VK_PIPELINE_STAGE_EARLY_FRAGMENT_TESTS_BIT` pipeline stage. Load operations for attachments with a color format execute in the `VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT` pipeline stage.

The store operation for each sample in an attachment happens-after any recorded command which accesses the sample in the last subpass where the attachment is used. Store operations for attachments with a depth/stencil format execute in the `VK_PIPELINE_STAGE_LATE_FRAGMENT_TESTS_BIT` pipeline stage. Store operations for attachments with a color format execute in the `VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT` pipeline stage.

If an attachment is not used by any subpass, then `loadOp`, `storeOp`, `stencilStoreOp`, and `stencilLoadOp` are ignored, and the attachment’s memory contents will not be modified by execution of a render pass instance.

The load and store operations apply on the first and last use of each view in the render pass, respectively. If a view index of an attachment is not included in the view mask in any subpass that uses it, then the load and store operations are ignored, and the attachment’s memory contents will not be modified by execution of a render pass instance.

During a render pass instance, input/color attachments with color formats that have a component size of 8, 16, or 32 bits **must** be represented in the attachment’s format throughout the instance. Attachments with other floating- or fixed-point color formats, or with depth components **may** be represented in a format with a precision higher than the attachment format, but **must** be represented with the same range. When such a component is loaded via the `loadOp`, it will be converted into an implementation-dependent format used by the render pass. Such components
must be converted from the render pass format, to the format of the attachment, before they are resolved or stored at the end of a render pass instance via storeOp. Conversions occur as described in Numeric Representation and Computation and Fixed-Point Data Conversions.

If flags includes VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT, then the attachment is treated as if it shares physical memory with another attachment in the same render pass. This information limits the ability of the implementation to reorder certain operations (like layout transitions and the loadOp) such that it is not improperly reordered against other uses of the same physical memory via a different attachment. This is described in more detail below.

If a render pass uses multiple attachments that alias the same device memory, those attachments must each include the VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT bit in their attachment description flags. Attachments aliasing the same memory occurs in multiple ways:

- Multiple attachments being assigned the same image view as part of framebuffer creation.
- Attachments using distinct image views that correspond to the same image subresource of an image.
- Attachments using views of distinct image subresources which are bound to overlapping memory ranges.

Note

Render passes must include subpass dependencies (either directly or via a subpass dependency chain) between any two subpasses that operate on the same attachment or aliasing attachments and those subpass dependencies must include execution and memory dependencies separating uses of the aliases, if at least one of those subpasses writes to one of the aliases. These dependencies must not include the VK_DEPENDENCY_BY_REGION_BIT if the aliases are views of distinct image subresources which overlap in memory.

Multiple attachments that alias the same memory must not be used in a single subpass. A given attachment index must not be used multiple times in a single subpass, with one exception: two subpass attachments can use the same attachment index if at least one use is as an input attachment and neither use is as a resolve or preserve attachment. In other words, the same view can be used simultaneously as an input and color or depth/stencil attachment, but must not be used as multiple color or depth/stencil attachments nor as resolve or preserve attachments. The precise set of valid scenarios is described in more detail below.

If a set of attachments alias each other, then all except the first to be used in the render pass must use an initialLayout of VK_IMAGE_LAYOUT_UNDEFINED, since the earlier uses of the other aliases make their contents undefined. Once an alias has been used and a different alias has been used after it, the first alias must not be used in any later subpasses. However, an application can assign the same image view to multiple aliasing attachment indices, which allows that image view to be used multiple times even if other aliases are used in between.
Note

Once an attachment needs the `VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT` bit, there should be no additional cost of introducing additional aliases, and using these additional aliases may allow more efficient clearing of the attachments on multiple uses via `VK_ATTACHMENT_LOAD_OP_CLEAR`. 
Valid Usage

- **finalLayout must** not be VK_IMAGE_LAYOUT_UNDEFINED or VK_IMAGE_LAYOUT_PREINITIALIZED

- If format is a color format, **initialLayout must** not be
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL,

- If format is a depth/stencil format, **initialLayout must** not be
  - VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL,

- If format is a color format, **finalLayout must** not be
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL,

- If format is a depth/stencil format, **finalLayout must** not be
  - VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL,

- If the separateDepthStencilLayouts feature is not enabled, **initialLayout must** not be
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL,

- If the separateDepthStencilLayouts feature is not enabled, **finalLayout must** not be
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL,

- If format is a color format, **initialLayout must** not be
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL,

- If format is a depth/stencil format which includes both depth and stencil aspects, **initialLayout must** not be
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL,

- If format is a depth/stencil format which includes both depth and stencil aspects, **finalLayout must** not be
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL,

- If format is a depth/stencil format which includes only the depth aspect, **initialLayout must** not be
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL,

- If format is a depth/stencil format which includes only the depth aspect, **finalLayout must** not be
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL
If `format` is a depth/stencil format which includes only the stencil aspect, `initialLayout` must not be `VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL` or `VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL`.

If `format` is a depth/stencil format which includes only the stencil aspect, `finalLayout` must not be `VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL` or `VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL`.

**Valid Usage (Implicit)**

- `flags` must be a valid combination of `VkAttachmentDescriptionFlagBits` values
- `format` must be a valid `VkFormat` value
- `samples` must be a valid `VkSampleCountFlagBits` value
- `loadOp` must be a valid `VkAttachmentLoadOp` value
- `storeOp` must be a valid `VkAttachmentStoreOp` value
- `stencilLoadOp` must be a valid `VkAttachmentLoadOp` value
- `stencilStoreOp` must be a valid `VkAttachmentStoreOp` value
- `initialLayout` must be a valid `VkImageLayout` value
- `finalLayout` must be a valid `VkImageLayout` value

Bits which can be set in `VkAttachmentDescription::flags` describing additional properties of the attachment are:

```cpp
typedef enum VkAttachmentDescriptionFlagBits {
    VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT = 0x00000001,
} VkAttachmentDescriptionFlagBits;
```

- `VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT` specifies that the attachment aliases the same device memory as other attachments.

```cpp
typedef VkFlags VkAttachmentDescriptionFlags;
```

`VkAttachmentDescriptionFlags` is a bitmask type for setting a mask of zero or more `VkAttachmentDescriptionFlagBits`.

Possible values of `VkAttachmentDescription::loadOp` and `stencilLoadOp`, specifying how the contents of the attachment are treated, are:
typedef enum VkAttachmentLoadOp {
    VK_ATTACHMENT_LOAD_OP_LOAD = 0,
    VK_ATTACHMENT_LOAD_OP_CLEAR = 1,
    VK_ATTACHMENT_LOAD_OP_DONT_CARE = 2,
} VkAttachmentLoadOp;

• **VK_ATTACHMENT_LOAD_OP_LOAD** specifies that the previous contents of the image within the render area will be preserved. For attachments with a depth/stencil format, this uses the access type `VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_READ_BIT`. For attachments with a color format, this uses the access type `VK_ACCESS_COLOR_ATTACHMENT_READ_BIT`.

• **VK_ATTACHMENT_LOAD_OP_CLEAR** specifies that the contents within the render area will be cleared to a uniform value, which is specified when a render pass instance is begun. For attachments with a depth/stencil format, this uses the access type `VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_WRITE_BIT`. For attachments with a color format, this uses the access type `VK_ACCESS_COLOR_ATTACHMENT_WRITE_BIT`.

• **VK_ATTACHMENT_LOAD_OP_DONT_CARE** specifies that the previous contents within the area need not be preserved; the contents of the attachment will be undefined inside the render area. For attachments with a depth/stencil format, this uses the access type `VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_WRITE_BIT`. For attachments with a color format, this uses the access type `VK_ACCESS_COLOR_ATTACHMENT_WRITE_BIT`.

Possible values of `VkAttachmentDescription::storeOp` and `stencilStoreOp`, specifying how the contents of the attachment are treated, are:

typedef enum VkAttachmentStoreOp {
    VK_ATTACHMENT_STORE_OP_STORE = 0,
    VK_ATTACHMENT_STORE_OP_DONT_CARE = 1,
    VK_ATTACHMENT_STORE_OP_NONE_QCOM = 1000301000,
} VkAttachmentStoreOp;

• **VK_ATTACHMENT_STORE_OP_STORE** specifies the contents generated during the render pass and within the render area are written to memory. For attachments with a depth/stencil format, this uses the access type `VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_WRITE_BIT`. For attachments with a color format, this uses the access type `VK_ACCESS_COLOR_ATTACHMENT_WRITE_BIT`.

• **VK_ATTACHMENT_STORE_OP_DONT_CARE** specifies the contents within the render area are not needed after rendering, and may be discarded; the contents of the attachment will be undefined inside the render area. For attachments with a depth/stencil format, this uses the access type `VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_WRITE_BIT`. For attachments with a color format, this uses the access type `VK_ACCESS_COLOR_ATTACHMENT_WRITE_BIT`.

• **VK_ATTACHMENT_STORE_OP_NONE_QCOM** specifies that the contents within the render area were not written during rendering, and may not be written to memory. If the attachment was written to during the renderpass, the contents of the attachment will be undefined inside the render area.
Note

VK_ATTACHMENT_STORE_OP_DONT_CARE can cause contents generated during previous render passes to be discarded before reaching memory, even if no write to the attachment occurs during the current render pass.

To specify which aspects of an input attachment can be read, add a VkRenderPassInputAttachmentAspectCreateInfo structure to the pNext chain of the VkRenderPassCreateInfo structure:

The VkRenderPassInputAttachmentAspectCreateInfo structure is defined as:

```c
typedef struct VkRenderPassInputAttachmentAspectCreateInfo {
    VkStructureType sType;
    const void* pNext;
    uint32_t aspectReferenceCount;
    const VkInputAttachmentAspectReference* pAspectReferences;
} VkRenderPassInputAttachmentAspectCreateInfo;
```

or the equivalent

```c
typedef VkRenderPassInputAttachmentAspectCreateInfoKHR;
```

- sType is the type of this structure.
- pNext is NULL or a pointer to an extension-specific structure.
- aspectReferenceCount is the number of elements in the pAspectReferences array.
- pAspectReferences is a pointer to an array of aspectReferenceCount VkInputAttachmentAspectReference structures containing a mask describing which aspect(s) can be accessed for a given input attachment within a given subpass.

An application can access any aspect of an input attachment that does not have a specified aspect mask in the pAspectReferences array. Otherwise, an application must not access aspect(s) of an input attachment other than those in its specified aspect mask.

**Valid Usage (Implicit)**

- sType must be VK_STRUCTURE_TYPE_RENDER_PASS_INPUT_ATTACHMENT_ASPECT_CREATE_INFO
- pAspectReferences must be a valid pointer to an array of aspectReferenceCount valid VkInputAttachmentAspectReference structures
- aspectReferenceCount must be greater than 0

The VkInputAttachmentAspectReference structure specifies an aspect mask for a specific input attachment of a specific subpass in the render pass.
subpass and inputAttachmentIndex index into the render pass as:

\[
pCreateInfo->pSubpasses[subpass].pInputAttachments[inputAttachmentIndex]
\]

```c
typedef struct VkInputAttachmentAspectReference {
    uint32_t subpass;
    uint32_t inputAttachmentIndex;
    VkImageAspectFlags aspectMask;
} VkInputAttachmentAspectReference;
```

or the equivalent

```c
typedef VkInputAttachmentAspectReference VkInputAttachmentAspectReferenceKHR;
```

- **subpass** is an index into the `pSubpasses` array of the parent `VkRenderPassCreateInfo` structure.
- **inputAttachmentIndex** is an index into the `pInputAttachments` of the specified subpass.
- **aspectMask** is a mask of which aspect(s) **can** be accessed within the specified subpass.

### Valid Usage

- **aspectMask** **must** not include `VK_IMAGE_ASPECT_METADATA_BIT`
- **aspectMask** **must** not include `VK_IMAGE_ASPECT_MEMORY_PLANE_i_BIT_EXT` for any index `i`

### Valid Usage (Implicit)

- **aspectMask** **must** be a valid combination of `VkImageAspectFlagBits` values
- **aspectMask** **must** not be 0

The `VkSubpassDescription` structure is defined as:

```c
typedef struct VkSubpassDescription {
    VkSubpassDescriptionFlags flags;
    VkPipelineBindPoint pipelineBindPoint;
    uint32_t inputAttachmentCount;
    const VkAttachmentReference* pInputAttachments;
    uint32_t colorAttachmentCount;
    const VkAttachmentReference* pColorAttachments;
    const VkAttachmentReference* pResolveAttachments;
    const VkAttachmentReference* pDepthStencilAttachment;
    uint32_t preserveAttachmentCount;
    const uint32_t* pPreserveAttachments;
} VkSubpassDescription;
```
• **flags** is a bitmask of `VkSubpassDescriptionFlagBits` specifying usage of the subpass.

• **pipelineBindPoint** is a `VkPipelineBindPoint` value specifying the pipeline type supported for this subpass.

• **inputAttachmentCount** is the number of input attachments.

• **pInputAttachments** is a pointer to an array of `VkAttachmentReference` structures defining the input attachments for this subpass and their layouts.

• **colorAttachmentCount** is the number of color attachments.

• **pColorAttachments** is a pointer to an array of `VkAttachmentReference` structures defining the color attachments for this subpass and their layouts.

• **pResolveAttachments** is an optional array of `VkAttachmentReference` structures defining the resolve attachments for this subpass and their layouts.

• **pDepthStencilAttachment** is a pointer to a `VkAttachmentReference` structure specifying the depth/stencil attachment for this subpass and its layout.

• **preserveAttachmentCount** is the number of preserved attachments.

• **pPreserveAttachments** is a pointer to an array of `VkAttachmentReference` structures identifying attachments that are not used by this subpass, but whose contents must be preserved throughout the subpass.

Each element of the `pInputAttachments` array corresponds to an input attachment index in a fragment shader, i.e. if a shader declares an image variable decorated with a `InputAttachmentIndex` value of X, then it uses the attachment provided in `pInputAttachments[X]`. Input attachments must also be bound to the pipeline in a descriptor set. If the attachment member of any element of `pInputAttachments` is `VK_ATTACHMENT_UNUSED`, the application must not read from the corresponding input attachment index. Fragment shaders can use subpass input variables to access the contents of an input attachment at the fragment’s (x, y, layer) framebuffer coordinates. Input attachments must not be used by any subpasses within a renderpass that enables render pass transform.

Each element of the `pColorAttachments` array corresponds to an output location in the shader, i.e. if the shader declares an output variable decorated with a `Location` value of X, then it uses the attachment provided in `pColorAttachments[X]`. If the attachment member of any element of `pColorAttachments` is `VK_ATTACHMENT_UNUSED`, writes to the corresponding location by a fragment are discarded.

If `flags` does not include `VK_SUBPASS_DESCRIPTION_SHADER_RESOLVE_BIT_QCOM`, and if `pResolveAttachments` is not NULL, each of its elements corresponds to a color attachment (the element in `pColorAttachments` at the same index), and a multisample resolve operation is defined for each attachment. At the end of each subpass, multisample resolve operations read the subpass’s color attachments, and resolve the samples for each pixel within the render area to the same pixel location in the corresponding resolve attachments, unless the resolve attachment index is `VK_ATTACHMENT_UNUSED`.

Similarly, if `flags` does not include `VK_SUBPASS_DESCRIPTION_SHADER_RESOLVE_BIT_QCOM`, and `pDepthStencilResolve::pDepthStencilResolveAttachment` is not NULL and does not have the value `VK_ATTACHMENT_UNUSED`, it corresponds to the depth/stencil attachment in `pDepthStencilAttachment`, and multisample resolve operations for depth and stencil are defined by
**VkSubpassDescriptionDepthStencilResolve::depthResolveMode** and **VkSubpassDescriptionDepthStencilResolve::stencilResolveMode**, respectively. At the end of each subpass, multisample resolve operations read the subpass’s depth/stencil attachment, and resolve the samples for each pixel to the same pixel location in the corresponding resolve attachment. If **VkSubpassDescriptionDepthStencilResolve::depthResolveMode** is **VK_RESOLVE_MODE_NONE**, then the depth component of the resolve attachment is not written to and its contents are preserved. Similarly, if **VkSubpassDescriptionDepthStencilResolve::stencilResolveMode** is **VK_RESOLVE_MODE_NONE**, then the stencil component of the resolve attachment is not written to and its contents are preserved. **VkSubpassDescriptionDepthStencilResolve::depthResolveMode** is ignored if the **VkFormat** of the **pDepthStencilResolveAttachment** does not have a depth component. Similarly, **VkSubpassDescriptionDepthStencilResolve::stencilResolveMode** is ignored if the **VkFormat** of the **pDepthStencilResolveAttachment** does not have a stencil component.

If the image subresource range referenced by the depth/stencil attachment is created with **VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT**, then the multisample resolve operation uses the sample locations state specified in the **sampleLocationsInfo** member of the element of the **VkRenderPassSampleLocationsBeginInfoEXT::pPostSubpassSampleLocations** for the subpass.

If **pDepthStencilAttachment** is **NULL**, or if its attachment index is **VK_ATTACHMENT_UNUSED**, it indicates that no depth/stencil attachment will be used in the subpass.

The contents of an attachment within the render area become undefined at the start of a subpass **S** if all of the following conditions are true:

- The attachment is used as a color, depth/stencil, or resolve attachment in any subpass in the render pass.
- There is a subpass **S₁** that uses or preserves the attachment, and a subpass dependency from **S₁** to **S**.
- The attachment is not used or preserved in subpass **S**.

In addition, the contents of an attachment within the render area become undefined at the start of a subpass **S** if all of the following conditions are true:

- **VK_SUBPASS_DESCRIPTION_SHADER_RESOLVE_BIT_QCOM** is set.
- The attachment is used as a color or depth/stencil in the subpass.

Once the contents of an attachment become undefined in subpass **S**, they remain undefined for subpasses in subpass dependency chains starting with subpass **S** until they are written again. However, they remain valid for subpasses in other subpass dependency chains starting with subpass **S₁** if those subpasses use or preserve the attachment.
Valid Usage

- `pipelineBindPoint` **must** be `VK_PIPELINE_BIND_POINT_GRAPHICS`.
- `colorAttachmentCount` **must** be less than or equal to `VkPhysicalDeviceLimits::maxColorAttachments`.
- If the first use of an attachment in this render pass is as an input attachment, and the attachment is not also used as a color or depth/stencil attachment in the same subpass, then `loadOp must` not be `VK_ATTACHMENT_LOAD_OP_CLEAR`.
- If `pResolveAttachments` is not `NULL`, for each resolve attachment that is not `VK_ATTACHMENT_UNUSED`, the corresponding color attachment **must** not have a sample count of `VK_SAMPLE_COUNT_1_BIT`.
- If `pResolveAttachments` is not `NULL`, for each resolve attachment that is not `VK_ATTACHMENT_UNUSED`, the corresponding color attachment **must** not be `VK_ATTACHMENT_UNUSED`.
- All attachments in `pColorAttachments` that are not `VK_ATTACHMENT_UNUSED` **must** have the same sample count.
- If `pDepthStencilAttachment` is not `NULL` and the attachment is not `VK_ATTACHMENT_UNUSED` then it **must** have a format whose features contain `VK_FORMAT_FEATURE_DEPTH_STENCIL_ATTACHMENT_BIT`.
- If the `VK_AMD_mixed_attachment_samples` extension is enabled, and all attachments in `pColorAttachments` that are not `VK_ATTACHMENT_UNUSED` must have a sample count that is smaller than or equal to the sample count of `pDepthStencilAttachment` if it is not `VK_ATTACHMENT_UNUSED`.
- If neither the `VK_AMD_mixed_attachment_samples` nor the `VK_NV_framebuffer_mixed_samples` extensions are enabled, and if `pDepthStencilAttachment` is not `VK_ATTACHMENT_UNUSED` and any attachments in `pColorAttachments` are not `VK_ATTACHMENT_UNUSED`, they **must** have the same sample count.
- The attachment member of each element of `pPreserveAttachments` **must** not be `VK_ATTACHMENT_UNUSED`.
- Each element of `pPreserveAttachments` **must** not also be an element of any other member of the subpass description.
• If any attachment is used by more than one `VkAttachmentReference` member, then each use **must** use the same layout

• If flags includes `VK_SUBPASS_DESCRIPTION_PER_VIEW_POSITION_X_ONLY_BIT_NVX`, it **must** also include `VK_SUBPASS_DESCRIPTION_PER_VIEW_ATTRIBUTES_BIT_NVX`

• If flags includes `VK_SUBPASS_DESCRIPTION_PER_VIEW_POSITION_X_ONLY_BIT_NVX`, and if `pResolveAttachments` is not NULL, then each resolve attachment **must** be `VK_ATTACHMENT_UNUSED`

• If flags includes `VK_SUBPASS_DESCRIPTION_SHADER_RESOLVE_BIT_QCOM`, and if `pResolveAttachments` is not NULL, then the depth/stencil resolve attachment **must** be `VK_ATTACHMENT_UNUSED`

• If flags includes `VK_SUBPASS_DESCRIPTION_SHADER_RESOLVE_BIT_QCOM`, and if `pDepthStencilResolveAttachmentKHR` is not NULL, then the depth/stencil resolve attachment **must** be `VK_ATTACHMENT_UNUSED`

• If flags includes `VK_SUBPASS_DESCRIPTION_SHADER_RESOLVE_BIT_QCOM`, then the subpass **must** be the last subpass in a subpass dependency chain

• If flags includes `VK_SUBPASS_DESCRIPTION_FRAGMENT_REGION_BIT_QCOM`, then the sample count of the input attachments **must** equal `rasterizationSamples`

• If flags includes `VK_SUBPASS_DESCRIPTION_FRAGMENT_REGION_BIT_QCOM`, and if `sampleShadingEnable` is enabled (explicitly or implicitly) then `minSampleShading` **must** equal 0.0

• If the render pass is created with `VK_RENDER_PASS_CREATE_TRANSFORM_BIT_QCOM` each of the elements of `pInputAttachments` **must** be `VK_ATTACHMENT_UNUSED`

---

**Valid Usage (Implicit)**

• flags **must** be a valid combination of `VkSubpassDescriptionFlagBits` values

• `pipelineBindPoint` **must** be a valid `VkPipelineBindPoint` value

• If `inputAttachmentCount` is not 0, `pInputAttachments` **must** be a valid pointer to an array of `inputAttachmentCount` valid `VkAttachmentReference` structures

• If `colorAttachmentCount` is not 0, `pColorAttachments` **must** be a valid pointer to an array of `colorAttachmentCount` valid `VkAttachmentReference` structures

• If `colorAttachmentCount` is not 0, and `pResolveAttachments` is not NULL, `pResolveAttachments` **must** be a valid pointer to an array of `colorAttachmentCount` valid `VkAttachmentReference` structures

• If `pDepthStencilAttachment` is not NULL, `pDepthStencilAttachment` **must** be a valid pointer to a valid `VkAttachmentReference` structure

• If `preserveAttachmentCount` is not 0, `pPreserveAttachments` **must** be a valid pointer to an array of `preserveAttachmentCount` `uint32_t` values

---

Bits which **can** be set in `VkSubpassDescription::flags`, specifying usage of the subpass, are:
typedef enum VkSubpassDescriptionFlagBits {
    VK_SUBPASS_DESCRIPTION_PER_VIEW_ATTRIBUTES_BIT_NVX = 0x00000001,
    VK_SUBPASS_DESCRIPTION_PER_VIEW_POSITION_X_ONLY_BIT_NVX = 0x00000002,
    VK_SUBPASS_DESCRIPTION_FRAGMENT_REGION_BIT_QCOM = 0x00000004,
    VK_SUBPASS_DESCRIPTION_SHADER_RESOLVE_BIT_QCOM = 0x00000008,
} VkSubpassDescriptionFlagBits;

• VK_SUBPASS_DESCRIPTION_PER_VIEW_ATTRIBUTES_BIT_NVX specifies that shaders compiled for this subpass write the attributes for all views in a single invocation of each vertex processing stage. All pipelines compiled against a subpass that includes this bit must write per-view attributes to the *PerViewNV[] shader outputs, in addition to the non-per-view (e.g. Position) outputs.

• VK_SUBPASS_DESCRIPTION_PER_VIEW_POSITION_X_ONLY_BIT_NVX specifies that shaders compiled for this subpass use per-view positions which only differ in value in the x component. Per-view viewport mask can also be used.

• VK_SUBPASS_DESCRIPTION_FRAGMENT_REGION_BIT_QCOM specifies that the framebuffer region is the fragment region, that is, the minimum region dependencies are by pixel rather than by sample, such that any fragment shader invocation can access any sample associated with that fragment shader invocation.

• VK_SUBPASS_DESCRIPTION_SHADER_RESOLVE_BIT_QCOM specifies that the subpass performs shader resolve operations.

Note
Shader resolve operations allow for custom resolve operations, but overdrawing pixels may have a performance and/or power cost. Furthermore, since the contents of any depth stencil attachment or color attachment is undefined at the beginning of a shader resolve subpass, any depth testing, stencil testing, or blending which sources these undefined values are also undefined.

typedef VkFlags VkSubpassDescriptionFlags;

VkSubpassDescriptionFlags is a bitmask type for setting a mask of zero or more VkSubpassDescriptionFlagBits.

The VkAttachmentReference structure is defined as:

typedef struct VkAttachmentReference {
    uint32_t attachment;
    VkImageLayout layout;
} VkAttachmentReference;

• attachment is either an integer value identifying an attachment at the corresponding index in VkRenderPassCreateInfo:pAttachments, or VK_ATTACHMENT_UNUSED to signify that this attachment is not used.

• layout is a VkImageLayout value specifying the layout the attachment uses during the subpass.
Valid Usage

- If attachment is not VK_ATTACHMENT_UNUSED, layout **must** not be VK_IMAGE_LAYOUT_UNDEFINED, VK_IMAGE_LAYOUT_PREINITIALIZED, VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL_KHR, VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL_KHR, VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL_KHR, or VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL_KHR.

Valid Usage (Implicit)

- **layout** **must** be a valid VkImageLayout value.

The `VkSubpassDependency` structure is defined as:

```c
typedef struct VkSubpassDependency {
    uint32_t                srcSubpass;
    uint32_t                dstSubpass;
    VkPipelineStageFlags    srcStageMask;
    VkPipelineStageFlags    dstStageMask;
    VkAccessFlags           srcAccessMask;
    VkAccessFlags           dstAccessMask;
    VkDependencyFlags       dependencyFlags;
} VkSubpassDependency;
```

- **srcSubpass** is the subpass index of the first subpass in the dependency, or VK_SUBPASS_EXTERNAL.
- **dstSubpass** is the subpass index of the second subpass in the dependency, or VK_SUBPASS_EXTERNAL.
- **srcStageMask** is a bitmask of VkPipelineStageFlagBits specifying the source stage mask.
- **dstStageMask** is a bitmask of VkPipelineStageFlagBits specifying the destination stage mask.
- **srcAccessMask** is a bitmask of VkAccessFlagBits specifying a source access mask.
- **dstAccessMask** is a bitmask of VkAccessFlagBits specifying a destination access mask.
- **dependencyFlags** is a bitmask of VkDependencyFlagBits.

If **srcSubpass** is equal to **dstSubpass** then the `VkSubpassDependency` describes a subpass self-dependency, and only constrains the pipeline barriers allowed within a subpass instance. Otherwise, when a render pass instance which includes a subpass dependency is submitted to a queue, it defines a memory dependency between the subpasses identified by **srcSubpass** and **dstSubpass**.

If **srcSubpass** is equal to VK_SUBPASS_EXTERNAL, the first synchronization scope includes commands that occur earlier in submission order than the `vkCmdBeginRenderPass` used to begin the render pass instance. Otherwise, the first set of commands includes all commands submitted as part of the subpass instance identified by **srcSubpass** and any load, store or multisample resolve operations on...
attachments used in `srcSubpass`. In either case, the first synchronization scope is limited to operations on the pipeline stages determined by the source stage mask specified by `srcStageMask`.

If `dstSubpass` is equal to `VK_SUBPASS_EXTERNAL`, the second synchronization scope includes commands that occur later in submission order than the `vkCmdEndRenderPass` used to end the render pass instance. Otherwise, the second set of commands includes all commands submitted as part of the subpass instance identified by `dstSubpass` and any load, store or multisample resolve operations on attachments used in `dstSubpass`. In either case, the second synchronization scope is limited to operations on the pipeline stages determined by the destination stage mask specified by `dstStageMask`.

The first access scope is limited to access in the pipeline stages determined by the source stage mask specified by `srcStageMask`. It is also limited to access types in the source access mask specified by `srcAccessMask`.

The second access scope is limited to access in the pipeline stages determined by the destination stage mask specified by `dstStageMask`. It is also limited to access types in the destination access mask specified by `dstAccessMask`.

The availability and visibility operations defined by a subpass dependency affect the execution of image layout transitions within the render pass.

**Note**

For non-attachment resources, the memory dependency expressed by subpass dependency is nearly identical to that of a `VkMemoryBarrier` (with matching `srcAccessMask` and `dstAccessMask` parameters) submitted as a part of a `vkCmdPipelineBarrier` (with matching `srcStageMask` and `dstStageMask` parameters). The only difference being that its scopes are limited to the identified subpasses rather than potentially affecting everything before and after.

For attachments however, subpass dependencies work more like a `VkImageMemoryBarrier` defined similarly to the `VkMemoryBarrier` above, the queue family indices set to `VK_QUEUE_FAMILY_IGNORED`, and layouts as follows:

- The equivalent to `oldLayout` is the attachment's layout according to the subpass description for `srcSubpass`.
- The equivalent to `newLayout` is the attachment's layout according to the subpass description for `dstSubpass`.
Valid Usage

- If the geometry shaders feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT`.
- If the geometry shaders feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT`.
- If the tessellation shaders feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT` or `VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT`.
- If the tessellation shaders feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT` or `VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT`.
- `srcSubpass` must be less than or equal to `dstSubpass`, unless one of them is `VK_SUBPASS_EXTERNAL`, to avoid cyclic dependencies and ensure a valid execution order.
- `srcSubpass` and `dstSubpass` must not both be equal to `VK_SUBPASS_EXTERNAL`.
- If `srcSubpass` is equal to `dstSubpass` and not all of the stages in `srcStageMask` and `dstStageMask` are framebuffer-space stages, the logically latest pipeline stage in `srcStageMask` must be logically earlier than or equal to the logically earliest pipeline stage in `dstStageMask`.
- Any access flag included in `srcAccessMask` must be supported by one of the pipeline stages in `srcStageMask`, as specified in the table of supported access types.
- Any access flag included in `dstAccessMask` must be supported by one of the pipeline stages in `dstStageMask`, as specified in the table of supported access types.
- If `srcSubpass` equals `dstSubpass`, and `srcStageMask` and `dstStageMask` both include a framebuffer-space stage, then `dependencyFlags` must include `VK_DEPENDENCY_BY_REGION_BIT`.
- If `dependencyFlags` includes `VK_DEPENDENCY_VIEW_LOCAL_BIT`, `srcSubpass` must not be equal to `VK_SUBPASS_EXTERNAL`.
- If `dependencyFlags` includes `VK_DEPENDENCY_VIEW_LOCAL_BIT`, `dstSubpass` must not be equal to `VK_SUBPASS_EXTERNAL`.
- If `srcSubpass` equals `dstSubpass` and that subpass has more than one bit set in the view mask, then `dependencyFlags` must include `VK_DEPENDENCY_VIEW_LOCAL_BIT`.
- If the mesh shaders feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV`.
- If the task shaders feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV`.
- If the mesh shaders feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV`.
- If the task shaders feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV`.
Valid Usage (Implicit)

- srcStageMask must be a valid combination of VkPipelineStageFlagBits values
- srcStageMask must not be 0
- dstStageMask must be a valid combination of VkPipelineStageFlagBits values
- dstStageMask must not be 0
- srcAccessMask must be a valid combination of VkAccessFlagBits values
- dstAccessMask must be a valid combination of VkAccessFlagBits values
- dependencyFlags must be a valid combination of VkDependencyFlagBits values

When multiview is enabled, the execution of the multiple views of one subpass may not occur simultaneously or even back-to-back, and rather may be interleaved with the execution of other subpasses. The load and store operations apply to attachments on a per-view basis. For example, an attachment using VK_ATTACHMENT_LOAD_OP_CLEAR will have each view cleared on first use, but the first use of one view may be temporally distant from the first use of another view.

Note

A good mental model for multiview is to think of a multiview subpass as if it were a collection of individual (per-view) subpasses that are logically grouped together and described as a single multiview subpass in the API. Similarly, a multiview attachment can be thought of like several individual attachments that happen to be layers in a single image. A view-local dependency between two multiview subpasses acts like a set of one-to-one dependencies between corresponding pairs of per-view subpasses. A view-global dependency between two multiview subpasses acts like a set of $N \times M$ dependencies between all pairs of per-view subpasses in the source and destination. Thus, it is a more compact representation which also makes clear the commonality and reuse that is present between views in a subpass. This interpretation motivates the answers to questions like “when does the load op apply” - it is on the first use of each view of an attachment, as if each view were a separate attachment.

If any two subpasses of a render pass activate transform feedback to the same bound transform feedback buffers, a subpass dependency must be included (either directly or via some intermediate subpasses) between them.

If there is no subpass dependency from VK_SUBPASS_EXTERNAL to the first subpass that uses an attachment, then an implicit subpass dependency exists from VK_SUBPASS_EXTERNAL to the first subpass it is used in. The implicit subpass dependency only exists if there exists an automatic layout transition away from initialLayout. The subpass dependency operates as if defined with the following parameters:
Similarly, if there is no subpass dependency from the last subpass that uses an attachment to `VK_SUBPASS_EXTERNAL`, then an implicit subpass dependency exists from the last subpass it is used in to `VK_SUBPASS_EXTERNAL`. The implicit subpass dependency only exists if there exists an automatic layout transition into `finalLayout`. The subpass dependency operates as if defined with the following parameters:

```c
VkSubpassDependency implicitDependency = {
    .srcSubpass = lastSubpass; // Last subpass attachment is used in
    .dstSubpass = VK_SUBPASS_EXTERNAL;
    .srcStageMask = VK_PIPELINE_STAGE_ALL_COMMANDS_BIT;
    .dstStageMask = VK_PIPELINE_STAGE_BOTTOM_OF_PIPE_BIT;
    .srcAccessMask = VK_ACCESS_INPUT_ATTACHMENT_READ_BIT |
                     VK_ACCESS_COLOR_ATTACHMENT_READ_BIT |
                     VK_ACCESS_COLOR_ATTACHMENT_WRITE_BIT |
                     VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_READ_BIT |
                     VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_WRITE_BIT;
    .dstAccessMask = 0;
    .dependencyFlags = 0;
};
```

As subpasses **may** overlap or execute out of order with regards to other subpasses unless a subpass dependency chain describes otherwise, the layout transitions required between subpasses **cannot** be known to an application. Instead, an application provides the layout that each attachment **must** be in at the start and end of a render pass, and the layout it **must** be in during each subpass it is used in. The implementation then **must** execute layout transitions between subpasses in order to guarantee that the images are in the layouts required by each subpass, and in the final layout at the end of the render pass.

Automatic layout transitions apply to the entire image subresource attached to the framebuffer. If the attachment view is a 2D or 2D array view of a 3D image, even if the attachment view only refers to a subset of the slices of the selected mip level of the 3D image, automatic layout transitions apply to the entire subresource referenced which is the entire mip level in this case.

Automatic layout transitions away from the layout used in a subpass happen-after the availability
operations for all dependencies with that subpass as the `srcSubpass`.

Automatic layout transitions into the layout used in a subpass happen-before the visibility operations for all dependencies with that subpass as the `dstSubpass`.

Automatic layout transitions away from `initialLayout` happens-after the availability operations for all dependencies with a `srcSubpass` equal to `VK_SUBPASS_EXTERNAL`, where `dstSubpass` uses the attachment that will be transitioned. For attachments created with `VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT`, automatic layout transitions away from `initialLayout` happen-after the availability operations for all dependencies with a `srcSubpass` equal to `VK_SUBPASS_EXTERNAL`, where `dstSubpass` uses any aliased attachment.

Automatic layout transitions into `finalLayout` happens-before the visibility operations for all dependencies with a `dstSubpass` equal to `VK_SUBPASS_EXTERNAL`, where `srcSubpass` uses the attachment that will be transitioned. For attachments created with `VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT`, automatic layout transitions into `finalLayout` happen-before the visibility operations for all dependencies with a `dstSubpass` equal to `VK_SUBPASS_EXTERNAL`, where `srcSubpass` uses any aliased attachment.

The image layout of the depth aspect of a depth/stencil attachment referring to an image created with `VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT` is dependent on the last sample locations used to render to the attachment, thus automatic layout transitions use the sample locations state specified in `VkRenderPassSampleLocationsBeginInfoEXT`.

Automatic layout transitions of an attachment referring to a depth/stencil image created with `VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT` use the sample locations the image subresource range referenced by the attachment was last rendered with. If the current render pass does not use the attachment as a depth/stencil attachment in any subpass that happens-before, the automatic layout transition uses the sample locations state specified in the `sampleLocationsInfo` member of the element of the `VkRenderPassSampleLocationsBeginInfoEXT::pAttachmentInitialSampleLocations` array for which the `attachmentIndex` member equals the attachment index of the attachment, if one is specified. Otherwise, the automatic layout transition uses the sample locations state specified in the `sampleLocationsInfo` member of the element of the `VkRenderPassSampleLocationsBeginInfoEXT::pPostSubpassSampleLocations` array for which the `subpassIndex` member equals the index of the subpass that last used the attachment as a depth/stencil attachment, if one is specified.

If no sample locations state has been specified for an automatic layout transition performed on an attachment referring to a depth/stencil image created with `VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT` the contents of the depth aspect of the depth/stencil attachment become undefined as if the layout of the attachment was transitioned from the `VK_IMAGE_LAYOUT_UNDEFINED` layout.

If two subpasses use the same attachment, and both subpasses use the attachment in a read-only layout, no subpass dependency needs to be specified between those subpasses. If an implementation treats those layouts separately, it **must** insert an implicit subpass dependency between those subpasses to separate the uses in each layout. The subpass dependency operates as if defined with the following parameters:
// Used for input attachments
VkPipelineStageFlags inputAttachmentStages = VK_PIPELINE_STAGE_FRAGMENT_SHADER_BIT;
VkAccessFlags inputAttachmentAccess = VK_ACCESS_INPUT_ATTACHMENT_READ_BIT;

// Used for depth/stencil attachments
VkPipelineStageFlags depthStencilAttachmentStages =
VK_PIPELINE_STAGE_EARLY_FRAGMENT_TESTS_BIT |
VK_PIPELINE_STAGE_LATE_FRAGMENT_TESTS_BIT;
VkAccessFlags depthStencilAttachmentAccess =
VK_ACCESS_DEPTH_STENCIL_ATTACHMENT_READ_BIT;

VkSubpassDependency implicitDependency = {
    .srcSubpass = firstSubpass;
    .dstSubpass = secondSubpass;
    .srcStageMask = inputAttachmentStages | depthStencilAttachmentStages;
    .dstStageMask = inputAttachmentStages | depthStencilAttachmentStages;
    .srcAccessMask = inputAttachmentAccess | depthStencilAttachmentAccess;
    .dstAccessMask = inputAttachmentAccess | depthStencilAttachmentAccess;
    .dependencyFlags = 0;
};

If a subpass uses the same attachment as both an input attachment and either a color attachment or a depth/stencil attachment, writes via the color or depth/stencil attachment are not automatically made visible to reads via the input attachment, causing a feedback loop, except in any of the following conditions:

- If the color components or depth/stencil components read by the input attachment are mutually exclusive with the components written by the color or depth/stencil attachments, then there is no feedback loop. This requires the graphics pipelines used by the subpass to disable writes to color components that are read as inputs via the colorWriteMask, and to disable writes to depth/stencil components that are read as inputs via depthWriteEnable or stencilTestEnable.

- If the attachment is used as an input attachment and depth/stencil attachment only, and the depth/stencil attachment is not written to.

- If a memory dependency is inserted between when the attachment is written and when it is subsequently read by later fragments. Pipeline barriers expressing a subpass self-dependency are the only way to achieve this, and one must be inserted every time a fragment will read values at a particular sample (x, y, layer, sample) coordinate, if those values have been written since the most recent pipeline barrier; or the since start of the subpass if there have been no pipeline barriers since the start of the subpass.

An attachment used as both an input attachment and a color attachment must be in the VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR or VK_IMAGE_LAYOUT_GENERAL layout. An attachment used as an input attachment and depth/stencil attachment must be in the VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR, VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL, or VK_IMAGE_LAYOUT_GENERAL layout. An attachment must not be used as both a depth/stencil attachment and a color attachment.
A more extensible version of render pass creation is also defined below.

To create a render pass, call:

```c
VkResult vkCreateRenderPass2KHR(
    VkDevice                                    device,
    const VkRenderPassCreateInfo2*              pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkRenderPass*                               pRenderPass);
```

- `device` is the logical device that creates the render pass.
- `pCreateInfo` is a pointer to a `VkRenderPassCreateInfo2` structure describing the parameters of the render pass.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
- `pRenderPass` is a pointer to a `VkRenderPass` handle in which the resulting render pass object is returned.

This command is functionally identical to `vkCreateRenderPass`, but includes extensible sub-structures that include `sType` and `pNext` parameters, allowing them to be more easily extended.

**Valid Usage (Implicit)**

- `device` must be a valid `VkDevice` handle
- `pCreateInfo` must be a valid pointer to a valid `VkRenderPassCreateInfo2` structure
- If `pAllocator` is not NULL, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- `pRenderPass` must be a valid pointer to a `VkRenderPass` handle

**Return Codes**

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

The `VkRenderPassCreateInfo2` structure is defined as:
typedef struct VkRenderPassCreateInfo2 {
    VkStructureType                    sType;
    const void*                        pNext;
    VkRenderPassCreateFlags            flags;
    uint32_t attachmentCount;
    const VkAttachmentDescription2*    pAttachments;
    uint32_t subpassCount;
    const VkSubpassDescription2*       pSubpasses;
    uint32_t dependencyCount;
    const VkSubpassDependency2*        pDependencies;
    uint32_t correlatedViewMaskCount;
    const uint32_t*                    pCorrelatedViewMasks;
} VkRenderPassCreateInfo2;

or the equivalent

typedef VkRenderPassCreateInfo2 VkRenderPassCreateInfo2KHR;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• flags is reserved for future use.
• attachmentCount is the number of attachments used by this render pass.
• pAttachments is a pointer to an array of attachmentCount VkAttachmentDescription2 structures describing the attachments used by the render pass.
• subpassCount is the number of subpasses to create.
• pSubpasses is a pointer to an array of subpassCount VkSubpassDescription2 structures describing each subpass.
• dependencyCount is the number of dependencies between pairs of subpasses.
• pDependencies is a pointer to an array of dependencyCount VkSubpassDependency structures describing dependencies between pairs of subpasses.
• correlatedViewMaskCount is the number of correlation masks.
• pCorrelatedViewMasks is a pointer to an array of view masks indicating sets of views that may be more efficient to render concurrently.

Parameters defined by this structure with the same name as those in VkRenderPassCreateInfo have the identical effect to those parameters; the child structures are variants of those used in VkRenderPassCreateInfo which add sType and pNext parameters, allowing them to be extended.

If the VkSubpassDescription2::viewMask member of any element of pSubpasses is not zero, multiview functionality is considered to be enabled for this render pass.

correlatedViewMaskCount and pCorrelatedViewMasks have the same effect as VkRenderPassMultiviewCreateInfo::correlationMaskCount and VkRenderPassMultiviewCreateInfo::correlatedViewMasks.
::pCorrelationMasks, respectively.
Valid Usage

- If any two subpasses operate on attachments with overlapping ranges of the same `VkDeviceMemory` object, and at least one subpass writes to that area of `VkDeviceMemory`, a subpass dependency must be included (either directly or via some intermediate subpasses) between them.

- If the attachment member of any element of `pInputAttachments`, `pColorAttachments`, `pResolveAttachments` or `pDepthStencilAttachment`, or the attachment indexed by any element of `pPreserveAttachments` in any given element of `pSubpasses` is bound to a range of a `VkDeviceMemory` object that overlaps with any other attachment in any subpass (including the same subpass), the `VkAttachmentDescription2` structures describing them must include `VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT` in flags.

- If the attachment member of any element of `pInputAttachments`, `pColorAttachments`, `pResolveAttachments` or `pDepthStencilAttachment`, or any element of `pPreserveAttachments` in any given element of `pSubpasses` is not `VK_ATTACHMENT_UNUSED`, it must be less than `attachmentCount`.

- For any member of `pAttachments` with a `loadOp` equal to `VK_ATTACHMENT_LOAD_OP_CLEAR`, the first use of that attachment must not specify a layout equal to `VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL`, or `VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL`.

- For any member of `pAttachments` with a `stencilLoadOp` equal to `VK_ATTACHMENT_LOAD_OP_CLEAR`, the first use of that attachment must not specify a layout equal to `VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL`, or `VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL`.

- For any element of `pDependencies`, if the `srcSubpass` is not `VK_SUBPASS_EXTERNAL`, all stage flags included in the `srcStageMask` member of that dependency must be a pipeline stage supported by the `pipeline` identified by the `pipelineBindPoint` member of the source subpass.

- For any element of `pDependencies`, if the `dstSubpass` is not `VK_SUBPASS_EXTERNAL`, all stage flags included in the `dstStageMask` member of that dependency must be a pipeline stage supported by the `pipeline` identified by the `pipelineBindPoint` member of the destination subpass.

- The set of bits included in any element of `pCorrelatedViewMasks` must not overlap with the set of bits included in any other element of `pCorrelatedViewMasks`.

- If the `VkSubpassDescription2::viewMask` member of all elements of `pSubpasses` is 0, `correlatedViewMaskCount` must be 0.

- The `VkSubpassDescription2::viewMask` member of all elements of `pSubpasses` must either all be 0, or all not be 0.

- If the `VkSubpassDescription2::viewMask` member of all elements of `pSubpasses` is 0, the dependencyFlags member of any element of `pDependencies` must not include `VK_DEPENDENCY_VIEW_LOCAL_BIT`.

- For any element of `pDependencies` where its `srcSubpass` member equals its `dstSubpass`.
member, if the viewMask member of the corresponding element of pSubpasses includes more than one bit, its dependencyFlags member must include VK_DEPENDENCY_VIEW_LOCAL_BIT

- The viewMask member must not have a bit set at an index greater than or equal to VkPhysicalDeviceLimits::maxFramebufferLayers

- If the attachment member of any element of the pInputAttachments member of any element of pSubpasses is not VK_ATTACHMENT_UNUSED, the aspectMask member of that element of pInputAttachments must only include aspects that are present in images of the format specified by the element of pAttachments specified by attachment

- The srcSubpass member of each element of pDependencies must be less than subpassCount

- The dstSubpass member of each element of pDependencies must be less than subpassCount

Valid Usage (Implicit)

- sType must be VK_STRUCTURE_TYPE_RENDER_PASS_CREATE_INFO_2

- pNext must be NULL or a pointer to a valid instance of VkRenderPassFragmentDensityMapCreateInfoEXT

- The sType value of each struct in the pNext chain must be unique

- flags must be a valid combination of VkRenderPassCreateFlagBits values

- If attachmentCount is not 0, pAttachments must be a valid pointer to an array of attachmentCount valid VkAttachmentDescription2 structures

- pSubpasses must be a valid pointer to an array of subpassCount valid VkSubpassDescription2 structures

- If dependencyCount is not 0, pDependencies must be a valid pointer to an array of dependencyCount valid VkSubpassDependency2 structures

- If correlatedViewMaskCount is not 0, pCorrelatedViewMasks must be a valid pointer to an array of correlatedViewMaskCount uint32_t values

- subpassCount must be greater than 0

The VkAttachmentDescription2 structure is defined as:
typedef struct VkAttachmentDescription2 {
    VkStructureType sType;
    const void* pNext;
    VkAttachmentDescriptionFlags flags;
    VkFormat format;
    VK_SAMPLE_COUNT_FLAG_BITS samples;
    VkAttachmentLoadOp loadOp;
    VkAttachmentStoreOp storeOp;
    VkAttachmentLoadOp stencilLoadOp;
    VkAttachmentStoreOp stencilStoreOp;
    VkImageLayout initialLayout;
    VkImageLayout finalLayout;
} VkAttachmentDescription2;

or the equivalent

typedef VkAttachmentDescription2 VkAttachmentDescription2KHR;

• \texttt{sType} is the type of this structure.
• \texttt{pNext} is \texttt{NULL} or a pointer to an extension-specific structure.
• \texttt{flags} is a bitmask of \texttt{VkAttachmentDescriptionFlagBits} specifying additional properties of the attachment.
• \texttt{format} is a \texttt{VkFormat} value specifying the format of the image that will be used for the attachment.
• \texttt{samples} is the number of samples of the image as defined in \texttt{VkSampleCountFlagBits}.
• \texttt{loadOp} is a \texttt{VkAttachmentLoadOp} value specifying how the contents of color and depth components of the attachment are treated at the beginning of the subpass where it is first used.
• \texttt{storeOp} is a \texttt{VkAttachmentStoreOp} value specifying how the contents of color and depth components of the attachment are treated at the end of the subpass where it is last used.
• \texttt{stencilLoadOp} is a \texttt{VkAttachmentLoadOp} value specifying how the contents of stencil components of the attachment are treated at the beginning of the subpass where it is first used.
• \texttt{stencilStoreOp} is a \texttt{VkAttachmentStoreOp} value specifying how the contents of stencil components of the attachment are treated at the end of the last subpass where it is used.
• \texttt{initialLayout} is the layout the attachment image subresource will be in when a render pass instance begins.
• \texttt{finalLayout} is the layout the attachment image subresource will be transitioned to when a render pass instance ends.

Parameters defined by this structure with the same name as those in \texttt{VkAttachmentDescription} have the identical effect to those parameters.

If the \texttt{separateDepthStencilLayouts} feature is enabled, and \texttt{format} is a depth/stencil format, \texttt{initialLayout} and \texttt{finalLayout} can be set to a layout that only specifies the layout of the depth
aspect.

If `format` is a depth/stencil format, and `initialLayout` only specifies the initial layout of the depth aspect of the attachment, the initial layout of the stencil aspect is specified by the `stencilInitialLayout` member of a `VkAttachmentDescriptionStencilLayout` structure included in the `pNext` chain. Otherwise, `initialLayout` describes the initial layout for all relevant image aspects.

If `format` is a depth/stencil format, and `finalLayout` only specifies the final layout of the depth aspect of the attachment, the final layout of the stencil aspect is specified by the `stencilFinalLayout` member of a `VkAttachmentDescriptionStencilLayout` structure included in the `pNext` chain. Otherwise, `finalLayout` describes the final layout for all relevant image aspects.
Valid Usage

- **finalLayout must not be** VK_IMAGE_LAYOUT_UNDEFINED or VK_IMAGE_LAYOUT_PREINITIALIZED.

- If format is a color format, **initialLayout must not be**
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL,
  - or

- If format is a depth/stencil format, **initialLayout must not be**
  - VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL.

- If format is a color format, **finalLayout must not be**
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL,
  - or

- If format is a depth/stencil format, **finalLayout must not be**
  - VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL.

- If the separateDepthStencilLayouts feature is not enabled, **initialLayout must not be**
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL,
  - or

- If the separateDepthStencilLayouts feature is not enabled, **finalLayout must not be**
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL,
  - or

- If format is a color format, **initialLayout must not be**
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL,
  - or

- If format is a color format, **finalLayout must not be**
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL,
  - or

- If format is a depth/stencil format which includes both depth and stencil aspects, and
  - **initialLayout is** VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL or
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL, the **pNext chain must include a**
  - VkAttachmentDescriptionStencilLayout structure.

- If format is a depth/stencil format which includes both depth and stencil aspects, and
  - **finalLayout is** VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL or
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL, the **pNext chain must include a**
  - VkAttachmentDescriptionStencilLayout structure.

- If format is a depth/stencil format which includes only the depth aspect, **initialLayout must not be**
  - VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL or
  - VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL.

- If format is a depth/stencil format which includes only the depth aspect, **finalLayout must**
not be VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL or
VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL

• If format is a depth/stencil format which includes only the stencil aspect, initialLayout must not be
VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL or
VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL

• If format is a depth/stencil format which includes only the stencil aspect, finalLayout must not be
VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL or
VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_ATTACHMENT_DESCRIPTION_2
• flags must be a valid combination of VkAttachmentDescriptionFlagBits values
• format must be a valid VkFormat value
• samples must be a valid VkSampleCountFlagBits value
• loadOp must be a valid VkAttachmentLoadOp value
• storeOp must be a valid VkAttachmentStoreOp value
• stencilLoadOp must be a valid VkAttachmentLoadOp value
• stencilStoreOp must be a valid VkAttachmentStoreOp value
• initialLayout must be a valid VkImageLayout value
• finalLayout must be a valid VkImageLayout value

The VkAttachmentDescriptionStencilLayout structure is defined as:

```c
typedef struct VkAttachmentDescriptionStencilLayout {
    VkStructureType    sType;
    void*              pNext;
    VkImageLayout      stencilInitialLayout;
    VkImageLayout      stencilFinalLayout;
} VkAttachmentDescriptionStencilLayout;
```

or the equivalent

```c
typedef VkAttachmentDescriptionStencilLayout VkAttachmentDescriptionStencilLayoutKHR;
```

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• stencilInitialLayout is the layout the stencil aspect of the attachment image subresource will be in when a render pass instance begins.
• stencilFinalLayout is the layout the stencil aspect of the attachment image subresource will be
transitioned to when a render pass instance ends.

### Valid Usage

- **stencilInitialLayout** must not be:
  - VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL

- **stencilFinalLayout** must not be:
  - VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL,
  - VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL

- **stencilFinalLayout** must not be:
  - VK_IMAGE_LAYOUT_UNDEFINED
  or
  - VK_IMAGE_LAYOUT_PREINITIALIZED

### Valid Usage (Implicit)

- **sType** must be:
  - VK_STRUCTURE_TYPE_ATTACHMENT_DESCRIPTION_STENCIL_LAYOUT

- **stencilInitialLayout** must be a valid VkImageLayout value

- **stencilFinalLayout** must be a valid VkImageLayout value

The **VkSubpassDescription2** structure is defined as:

```c
typedef struct VkSubpassDescription2 {
    VkStructureType                  sType;
    const void*                      pNext;
    VkSubpassDescriptionFlags        flags;
    VkPipelineBindPoint              pipelineBindPoint;
    uint32_t                         viewMask;
    uint32_t                         inputAttachmentCount;
    const VkAttachmentReference2*    pInputAttachments;
    uint32_t                         colorAttachmentCount;
    const VkAttachmentReference2*    pColorAttachments;
    const VkAttachmentReference2*    pResolveAttachments;
    const VkAttachmentReference2*    pDepthStencilAttachment;
    uint32_t                         preserveAttachmentCount;
    const uint32_t*                  pPreserveAttachments;
} VkSubpassDescription2;
```

or the equivalent
typedef VkSubpassDescription2 VkSubpassDescription2KHR;

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `flags` is a bitmask of `VkSubpassDescriptionFlagBits` specifying usage of the subpass.
- `pipelineBindPoint` is a `VkPipelineBindPoint` value specifying the pipeline type supported for this subpass.
- `viewMask` is a bitfield of view indices describing which views rendering is broadcast to in this subpass, when multiview is enabled.
- `inputAttachmentCount` is the number of input attachments.
- `pInputAttachments` is a pointer to an array of `VkAttachmentReference2` structures defining the input attachments for this subpass and their layouts.
- `colorAttachmentCount` is the number of color attachments.
- `pColorAttachments` is a pointer to an array of `VkAttachmentReference2` structures defining the color attachments for this subpass and their layouts.
- `pResolveAttachments` is an optional array of `colorAttachmentCount` `VkAttachmentReference2` structures defining the resolve attachments for this subpass and their layouts.
- `pDepthStencilAttachment` is a pointer to a `VkAttachmentReference2` structure specifying the depth/stencil attachment for this subpass and its layout.
- `preserveAttachmentCount` is the number of preserved attachments.
- `pPreserveAttachments` is a pointer to an array of `preserveAttachmentCount` render pass attachment indices identifying attachments that are not used by this subpass, but whose contents must be preserved throughout the subpass.

Parameters defined by this structure with the same name as those in `VkSubpassDescription` have the identical effect to those parameters.

`viewMask` has the same effect for the described subpass as `VkRenderPassMultiviewCreateInfo`'s `pViewMasks` has on each corresponding subpass.
Valid Usage

• pipelineBindPoint must be VK_PIPELINE_BIND_POINT_GRAPHICS

• colorAttachmentCount must be less than or equal to VkPhysicalDeviceLimits::maxColorAttachments

• If the first use of an attachment in this render pass is as an input attachment, and the attachment is not also used as a color or depth/stencil attachment in the same subpass, then loadOp must not be VK_ATTACHMENT_LOAD_OP_CLEAR

• If pResolveAttachments is not NULL, for each resolve attachment that does not have the value VK_ATTACHMENT_UNUSED, the corresponding color attachment must not have the value VK_ATTACHMENT_UNUSED

• If pResolveAttachments is not NULL, for each resolve attachment that is not VK_ATTACHMENT_UNUSED, the corresponding color attachment must not have a sample count of VK_SAMPLE_COUNT_1_BIT

• If pResolveAttachments is not NULL, each resolve attachment that is not VK_ATTACHMENT_UNUSED must have a sample count of VK_SAMPLE_COUNT_1_BIT

• Any given element of pResolveAttachments must have the same VkFormat as its corresponding color attachment

• All attachments in pColorAttachments that are not VK_ATTACHMENT_UNUSED must have the same sample count

• All attachments in pInputAttachments that are not VK_ATTACHMENT_UNUSED must have formats whose features contain at least one of VK_FORMAT_FEATURE_COLOR_ATTACHMENT_BIT or VK_FORMAT_FEATURE_DEPTH_STENCIL_ATTACHMENT_BIT

• All attachments in pColorAttachments that are not VK_ATTACHMENT_UNUSED must have formats whose features contain VK_FORMAT_FEATURE_COLOR_ATTACHMENT_BIT

• All attachments in pResolveAttachments that are not VK_ATTACHMENT_UNUSED must have formats whose features contain VK_FORMAT_FEATURE_COLOR_ATTACHMENT_BIT

• If pDepthStencilAttachment is not NULL and the attachment is not VK_ATTACHMENT_UNUSED then it must have a format whose features contain VK_FORMAT_FEATURE_DEPTH_STENCIL_ATTACHMENT_BIT

• If the VK_AMD_mixed_attachment_samples extension is enabled, all attachments in pColorAttachments that are not VK_ATTACHMENT_UNUSED must have a sample count that is smaller than or equal to the sample count of pDepthStencilAttachment if it is not VK_ATTACHMENT_UNUSED

• If neither the VK_AMD_mixed_attachment_samples nor the VK_NV_framebuffer_mixed_samples extensions are enabled, and if pDepthStencilAttachment is not VK_ATTACHMENT_UNUSED and any attachments in pColorAttachments are not VK_ATTACHMENT_UNUSED, they must have the same sample count

• The attachment member of any element of pPreserveAttachments must not be VK_ATTACHMENT_UNUSED

• Any given element of pPreserveAttachments must not also be an element of any other member of the subpass description
• If any attachment is used by more than one `VkAttachmentReference` member, then each use must use the same layout.

• If `flags` includes `VK_SUBPASS_DESCRIPTION_PER_VIEW_POSITION_X_ONLY_BIT_NVX`, it must also include `VK_SUBPASS_DESCRIPTION_PER_VIEW_ATTRIBUTES_BIT_NVX`.

• If the `attachment` member of any element of `pInputAttachments` is not `VK_ATTACHMENT_UNUSED`, then the `aspectMask` member must be a valid combination of `VkImageAspectFlagBits`.

• If the `attachment` member of any element of `pInputAttachments` is not `VK_ATTACHMENT_UNUSED`, then the `aspectMask` member must not be 0.

• If the `attachment` member of any element of `pInputAttachments` is not `VK_ATTACHMENT_UNUSED`, then the `aspectMask` member must not include `VK_IMAGE_ASPECT_METADATA_BIT`.

Valid Usage (Implicit)

• `sType` must be `VK_STRUCTURE_TYPE_SUBPASS_DESCRIPTION_2`.

• `flags` must be a valid combination of `VkSubpassDescriptionFlagBits` values.

• `pipelineBindPoint` must be a valid `VkPipelineBindPoint` value.

• If `inputAttachmentCount` is not 0, `pInputAttachments` must be a valid pointer to an array of `inputAttachmentCount` valid `VkAttachmentReference2` structures.

• If `colorAttachmentCount` is not 0, `pColorAttachments` must be a valid pointer to an array of `colorAttachmentCount` valid `VkAttachmentReference2` structures.

• If `colorAttachmentCount` is not 0, and `pResolveAttachments` is not NULL, `pResolveAttachments` must be a valid pointer to an array of `colorAttachmentCount` valid `VkAttachmentReference2` structures.

• If `pDepthStencilAttachment` is not NULL, `pDepthStencilAttachment` must be a valid pointer to a valid `VkAttachmentReference2` structure.

• If `preserveAttachmentCount` is not 0, `pPreserveAttachments` must be a valid pointer to an array of `preserveAttachmentCount` `uint32_t` values.

If the `pNext` list of `VkSubpassDescription2` includes a `VkSubpassDescriptionDepthStencilResolve` structure, then that structure describes multisample resolve operations for the depth/stencil attachment in a subpass.

The `VkSubpassDescriptionDepthStencilResolve` structure is defined as:

```c
typedef struct VkSubpassDescriptionDepthStencilResolve {
    VkStructureType sType;
    const void* pNext;
    VkResolveModeFlagBits depthResolveMode;
    VkResolveModeFlagBits stencilResolveMode;
    const VkAttachmentReference2* pDepthStencilResolveAttachment;
} VkSubpassDescriptionDepthStencilResolve;
```
or the equivalent

```c
typedef VkSubpassDescriptionDepthStencilResolve
    VkSubpassDescriptionDepthStencilResolveKHR;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **depthResolveMode** is a bitmask of `VkResolveModeFlagBits` describing the depth resolve mode.
- **stencilResolveMode** is a bitmask of `VkResolveModeFlagBits` describing the stencil resolve mode.
- **pDepthStencilResolveAttachment** is an optional `VkAttachmentReference` structure defining the depth/stencil resolve attachment for this subpass and its layout.
Valid Usage

- If `pDepthStencilResolveAttachment` is not NULL and does not have the value `VK_ATTACHMENT_UNUSED`, `pDepthStencilAttachment` must not have the value `VK_ATTACHMENT_UNUSED`.

- If `pDepthStencilResolveAttachment` is not NULL and does not have the value `VK_ATTACHMENT_UNUSED`, `depthResolveMode` and `stencilResolveMode` must not both be `VK_RESOLVE_MODE_NONE`.

- If `pDepthStencilResolveAttachment` is not NULL and does not have the value `VK_ATTACHMENT_UNUSED`, `pDepthStencilAttachment` must not have a sample count of `VK_SAMPLE_COUNT_1_BIT`.

- If `pDepthStencilResolveAttachment` is not NULL and does not have the value `VK_ATTACHMENT_UNUSED`, `pDepthStencilResolveAttachment` must have a sample count of `VK_SAMPLE_COUNT_1_BIT`.

- If `pDepthStencilResolveAttachment` is not NULL and does not have the value `VK_ATTACHMENT_UNUSED` then it must have a format whose features contain `VK_FORMAT_FEATURE_DEPTH_STENCIL_ATTACHMENT_BIT`.

- If the `VkFormat` of `pDepthStencilResolveAttachment` has a depth component, then the `VkFormat` of `pDepthStencilAttachment` must have a depth component with the same number of bits and numerical type.

- If the `VkFormat` of `pDepthStencilResolveAttachment` has a stencil component, then the `VkFormat` of `pDepthStencilAttachment` must have a stencil component with the same number of bits and numerical type.

- The value of `depthResolveMode` must be one of the bits set in `VkPhysicalDeviceDepthStencilResolveProperties::supportedDepthResolveModes` or `VK_RESOLVE_MODE_NONE`.

- The value of `stencilResolveMode` must be one of the bits set in `VkPhysicalDeviceDepthStencilResolveProperties::supportedStencilResolveModes` or `VK_RESOLVE_MODE_NONE`.

- If the `VkFormat` of `pDepthStencilResolveAttachment` has both depth and stencil components, `VkPhysicalDeviceDepthStencilResolveProperties::independentResolve` is `VK_FALSE`, and `VkPhysicalDeviceDepthStencilResolveProperties::independentResolveNone` is `VK_FALSE`, then the values of `depthResolveMode` and `stencilResolveMode` must be identical.

- If the `VkFormat` of `pDepthStencilResolveAttachment` has both depth and stencil components, `VkPhysicalDeviceDepthStencilResolveProperties::independentResolve` is `VK_FALSE` and `VkPhysicalDeviceDepthStencilResolveProperties::independentResolveNone` is `VK_TRUE`, then the values of `depthResolveMode` and `stencilResolveMode` must be identical or one of them must be `VK_RESOLVE_MODE_NONE`.
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_SUBPASS_DESCRIPTION_DEPTH_STENCIL_RESOLVE`
- `depthResolveMode` must be a valid `VkResolveModeFlagBits` value
- `stencilResolveMode` must be a valid `VkResolveModeFlagBits` value
- If `pDepthStencilResolveAttachment` is not `NULL`, `pDepthStencilResolveAttachment` must be a valid pointer to a valid `VkAttachmentReference2` structure

Possible values of `VkSubpassDescriptionDepthStencilResolve::depthResolveMode` and `stencilResolveMode`, specifying the depth and stencil resolve modes, are:

```c
typedef enum VkResolveModeFlagBits {
    VK_RESOLVE_MODE_NONE = 0,
    VK_RESOLVE_MODE_SAMPLE_ZERO_BIT = 0x00000001,
    VK_RESOLVE_MODE_AVERAGE_BIT = 0x00000002,
    VK_RESOLVE_MODE_MIN_BIT = 0x00000004,
    VK_RESOLVE_MODE_MAX_BIT = 0x00000008,
    VK_RESOLVE_MODE_NONE_KHR = VK_RESOLVE_MODE_NONE,
    VK_RESOLVE_MODE_SAMPLE_ZERO_BIT_KHR = VK_RESOLVE_MODE_SAMPLE_ZERO_BIT,
    VK_RESOLVE_MODE_AVERAGE_BIT_KHR = VK_RESOLVE_MODE_AVERAGE_BIT,
    VK_RESOLVE_MODE_MIN_BIT_KHR = VK_RESOLVE_MODE_MIN_BIT,
    VK_RESOLVE_MODE_MAX_BIT_KHR = VK_RESOLVE_MODE_MAX_BIT,
} VkResolveModeFlagBits;
```

or the equivalent

```c
typedef VkResolveModeFlagBits VkResolveModeFlagBitsKHR;
```

- `VK_RESOLVE_MODE_NONE` indicates that no resolve operation is done.
- `VK_RESOLVE_MODE_SAMPLE_ZERO_BIT` indicates that result of the resolve operation is equal to the value of sample 0.
- `VK_RESOLVE_MODE_AVERAGE_BIT` indicates that result of the resolve operation is the average of the sample values.
- `VK_RESOLVE_MODE_MIN_BIT` indicates that result of the resolve operation is the minimum of the sample values.
- `VK_RESOLVE_MODE_MAX_BIT` indicates that result of the resolve operation is the maximum of the sample values.

```c
typedef VkFlags VkResolveModeFlags;
```

or the equivalent
typedef VkResolveModeFlags VkResolveModeFlagsKHR;

VkResolveModeFlags is a bitmask type for setting a mask of zero or more VkResolveModeFlagBits.

The VkAttachmentReference2 structure is defined as:

typedef struct VkAttachmentReference2 {
    VkStructureType       sType;
    const void*           pNext;
    uint32_t              attachment;
    VkImageLayout         layout;
    VkImageAspectFlags    aspectMask;
} VkAttachmentReference2;

or the equivalent

typedef VkAttachmentReference2 VkAttachmentReference2KHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **attachment** is either an integer value identifying an attachment at the corresponding index in VkRenderPassCreateInfo::pAttachments, or VK_ATTACHMENT_UNUSED to signify that this attachment is not used.
- **layout** is a VkImageLayout value specifying the layout the attachment uses during the subpass.
- **aspectMask** is a mask of which aspect(s) can be accessed within the specified subpass as an input attachment.

Parameters defined by this structure with the same name as those in VkAttachmentReference have the identical effect to those parameters.

**aspectMask** is ignored when this structure is used to describe anything other than an input attachment reference.

If the separateDepthStencilLayouts feature is enabled, and **attachment** has a depth/stencil format, **layout** can be set to a layout that only specifies the layout of the depth aspect.

If **layout** only specifies the layout of the depth aspect of the attachment, the layout of the stencil aspect is specified by the **stencilLayout** member of a VkAttachmentReferenceStencilLayout structure included in the **pNext** chain. Otherwise, **layout** describes the layout for all relevant image aspects.
Valid Usage

- If attachment is not VK_ATTACHMENT_UNUSED, layout must not be VK_IMAGE_LAYOUT_UNDEFINED, VK_IMAGE_LAYOUT_PRESENT_SRC_KHR, or VK_IMAGE_LAYOUT_PREINITIALIZED.

- If attachment is not VK_ATTACHMENT_UNUSED, and aspectMask does not include VK_IMAGE_ASPECT_STENCIL_BIT or VK_IMAGE_ASPECT_DEPTH_BIT, layout must not be VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL, or VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL.

- If attachment is not VK_ATTACHMENT_UNUSED, and aspectMask does not include VK_IMAGE_ASPECT_COLOR_BIT, layout must not be VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL.

- If the separateDepthStencilLayouts feature is not enabled, and attachment is not VK_ATTACHMENT_UNUSED, layout must not be VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL, VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL, or VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL.

- If attachment is not VK_ATTACHMENT_UNUSED, and aspectMask includes both VK_IMAGE_ASPECT_DEPTH_BIT and VK_IMAGE_ASPECT_STENCIL_BIT, and layout is VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL or VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL, the pNext chain must include a VkAttachmentReferenceStencilLayout structure.

Valid Usage (Implicit)

- sType must be VK_STRUCTURE_TYPE_ATTACHMENT_REFERENCE_2.
- layout must be a valid VkImageLayout value.

The VkAttachmentReferenceStencilLayout structure is defined as:
```c
typedef struct VkAttachmentReferenceStencilLayout {
    VkStructureType    sType;
    void*              pNext;
    VkImageLayout      stencilLayout;
} VkAttachmentReferenceStencilLayout;
```

or the equivalent

```c
typedef VkAttachmentReferenceStencilLayout VkAttachmentReferenceStencilLayoutKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `stencilLayout` is a `VkImageLayout` value specifying the layout the stencil aspect of the attachment uses during the subpass.

**Valid Usage**

- `stencilLayout` must not be `VK_IMAGE_LAYOUT_UNDEFINED`, `VK_IMAGE_LAYOUT_PREINITIALIZED`, `VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL`, `VK_IMAGE_LAYOUT_PRESENT_SRC_KHR` or

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_ATTACHMENT_REFERENCE_STENCIL_LAYOUT`
- `stencilLayout` must be a valid `VkImageLayout` value

The `VkSubpassDependency2` structure is defined as:
```c
typedef struct VkSubpassDependency2 {
    VkStructureType         sType;
    const void*             pNext;
    uint32_t                srcSubpass;
    uint32_t                dstSubpass;
    VkPipelineStageFlags    srcStageMask;
    VkPipelineStageFlags    dstStageMask;
    VkAccessFlags           srcAccessMask;
    VkAccessFlags           dstAccessMask;
    VkDependencyFlags       dependencyFlags;
    int32_t                 viewOffset;
} VkSubpassDependency2;
```

or the equivalent

```c
typedef VkSubpassDependency2 VkSubpassDependency2KHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **srcSubpass** is the subpass index of the first subpass in the dependency, or `VK_SUBPASS_EXTERNAL`.
- **dstSubpass** is the subpass index of the second subpass in the dependency, or `VK_SUBPASS_EXTERNAL`.
- **srcStageMask** is a bitmask of `VkPipelineStageFlagBits` specifying the *source stage mask*.
- **dstStageMask** is a bitmask of `VkPipelineStageFlagBits` specifying the *destination stage mask*.
- **srcAccessMask** is a bitmask of `VkAccessFlagBits` specifying a *source access mask*.
- **dstAccessMask** is a bitmask of `VkAccessFlagBits` specifying a *destination access mask*.
- **dependencyFlags** is a bitmask of `VkDependencyFlagBits`.
- **viewOffset** controls which views in the source subpass the views in the destination subpass depend on.

Parameters defined by this structure with the same name as those in `VkSubpassDependency` have the identical effect to those parameters.

`viewOffset` has the same effect for the described subpass dependency as `VkRenderPassMultiviewCreateInfo::pViewOffsets` has on each corresponding subpass dependency.
Valid Usage

- If the **geometry shaders** feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT`

- If the **geometry shaders** feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_GEOMETRY_SHADER_BIT`

- If the **tessellation shaders** feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT` or `VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT`

- If the **tessellation shaders** feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_TESSELLATION_CONTROL_SHADER_BIT` or `VK_PIPELINE_STAGE_TESSELLATION_EVALUATION_SHADER_BIT`

- `srcSubpass` must be less than or equal to `dstSubpass`, unless one of them is `VK_SUBPASS_EXTERNAL`, to avoid cyclic dependencies and ensure a valid execution order

- `srcSubpass` and `dstSubpass` must not both be equal to `VK_SUBPASS_EXTERNAL`

- If `srcSubpass` is equal to `dstSubpass` and not all of the stages in `srcStageMask` and `dstStageMask` are framebuffer-space stages, the logically latest pipeline stage in `srcStageMask` must be logically earlier than or equal to the logically earliest pipeline stage in `dstStageMask`

- Any access flag included in `srcAccessMask` must be supported by one of the pipeline stages in `srcStageMask`, as specified in the table of supported access types

- Any access flag included in `dstAccessMask` must be supported by one of the pipeline stages in `dstStageMask`, as specified in the table of supported access types

- If `dependencyFlags` includes `VK_DEPENDENCY_VIEW_LOCAL_BIT`, `srcSubpass` must not be equal to `VK_SUBPASS_EXTERNAL`

- If `dependencyFlags` includes `VK_DEPENDENCY_VIEW_LOCAL_BIT`, `dstSubpass` must not be equal to `VK_SUBPASS_EXTERNAL`

- If `srcSubpass` equals `dstSubpass`, and `srcStageMask` and `dstStageMask` both include a framebuffer-space stage, then `dependencyFlags` must include `VK_DEPENDENCY_BY_REGION_BIT`

- If `viewOffset` is not equal to 0, `srcSubpass` must not be equal to `dstSubpass`

- If `dependencyFlags` does not include `VK_DEPENDENCY_VIEW_LOCAL_BIT`, `viewOffset` must be 0

- If the **mesh shaders** feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV`

- If the **task shaders** feature is not enabled, `srcStageMask` must not contain `VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV`

- If the **mesh shaders** feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_MESH_SHADER_BIT_NV`

- If the **task shaders** feature is not enabled, `dstStageMask` must not contain `VK_PIPELINE_STAGE_TASK_SHADER_BIT_NV`
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_SUBPASS_DEPENDENCY_2`
- `srcStageMask` must be a valid combination of `VkPipelineStageFlagBits` values
- `srcStageMask` must not be `0`
- `dstStageMask` must be a valid combination of `VkPipelineStageFlagBits` values
- `dstStageMask` must not be `0`
- `srcAccessMask` must be a valid combination of `VkAccessFlagBits` values
- `dstAccessMask` must be a valid combination of `VkAccessFlagBits` values
- `dependencyFlags` must be a valid combination of `VkDependencyFlagBits` values

To destroy a render pass, call:

```c
void vkDestroyRenderPass(
    VkDevice device,  // device is the logical device that destroys the render pass.
    VkRenderPass renderPass, // renderPass is the handle of the render pass to destroy.
    const VkAllocationCallbacks* pAllocator);  // pAllocator controls host memory allocation as described in the Memory Allocation chapter.
```

Valid Usage

- All submitted commands that refer to `renderPass` must have completed execution
- If `VkAllocationCallbacks` were provided when `renderPass` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `renderPass` was created, `pAllocator` must be `NULL`

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- If `renderPass` is not `VK_NULL_HANDLE`, `renderPass` must be a valid `VkRenderPass` handle
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- If `renderPass` is a valid handle, it must have been created, allocated, or retrieved from `device`
7.2. Render Pass Compatibility

Framebuffers and graphics pipelines are created based on a specific render pass object. They must only be used with that render pass object, or one compatible with it.

Two attachment references are compatible if they have matching format and sample count, or are both `VK_ATTACHMENT_UNUSED` or the pointer that would contain the reference is `NULL`.

Two arrays of attachment references are compatible if all corresponding pairs of attachments are compatible. If the arrays are of different lengths, attachment references not present in the smaller array are treated as `VK_ATTACHMENT_UNUSED`.

Two render passes are compatible if their corresponding color, input, resolve, and depth/stencil attachment references are compatible and if they are otherwise identical except for:

- Initial and final image layout in attachment descriptions
- Load and store operations in attachment descriptions
- Image layout in attachment references

As an additional special case, if two render passes have a single subpass, the resolve attachment reference and depth/stencil resolve mode compatibility requirements are ignored.

A framebuffer is compatible with a render pass if it was created using the same render pass or a compatible render pass.

7.3. Framebuffers

Render passes operate in conjunction with `framebuffers`. Framebuffers represent a collection of specific memory attachments that a render pass instance uses.

Framebuffers are represented by `VkFramebuffer` handles:

```cpp
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkFramebuffer)
```

To create a framebuffer, call:

```cpp
VkResult vkCreateFramebuffer(
    VkDevice device,
    const VkFramebufferCreateInfo* pCreateInfo,
    const VkAllocationCallbacks* pAllocator,
    VkFramebuffer* pFramebuffer);
```
• **device** is the logical device that creates the framebuffer.

• **pCreateInfo** is a pointer to a `VkFramebufferCreateInfo` structure describing additional information about framebuffer creation.

• **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.

• **pFramebuffer** is a pointer to a `VkFramebuffer` handle in which the resulting framebuffer object is returned.

### Valid Usage

- If `pCreateInfo->flags` does not include `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, and `attachmentCount` is not 0, each element of `pCreateInfo->pAttachments` must have been created on `device`.

### Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pCreateInfo** must be a valid pointer to a valid `VkFramebufferCreateInfo` structure
- If `pAllocator` is not NULL, **pAllocator** must be a valid pointer to a valid `VkAllocationCallbacks` structure
- **pFramebuffer** must be a valid pointer to a `VkFramebuffer` handle

### Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

The `VkFramebufferCreateInfo` structure is defined as:
typedef struct VkFramebufferCreateInfo {
    VkStructureType             sType;
    const void*                 pNext;
    VkFramebufferCreateFlags    flags;
    VkRenderPass                renderPass;
    uint32_t                    attachmentCount;
    const VkImageView*          pAttachments;
    uint32_t                    width;
    uint32_t                    height;
    uint32_t                    layers;
} VkFramebufferCreateInfo;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• flags is a bitmask of VkFramebufferCreateFlagBits
• renderPass is a render pass defining what render passes the framebuffer will be compatible with. See Render Pass Compatibility for details.
• attachmentCount is the number of attachments.
• pAttachments is a pointer to an array of VkImageView handles, each of which will be used as the corresponding attachment in a render pass instance. If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, this parameter is ignored.
• width, height and layers define the dimensions of the framebuffer. If the render pass uses multiview, then layers must be one and each attachment requires a number of layers that is greater than the maximum bit index set in the view mask in the subpasses in which it is used.

Applications must ensure that all accesses to memory that backs image subresources used as attachments in a given renderpass instance either happen-before the load operations for those attachments, or happen-after the store operations for those attachments.

For depth/stencil attachments, each aspect can be used separately as attachments and non-attachments as long as the non-attachment accesses are also via an image subresource in either the VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL layout or the VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL layout, and the attachment resource uses whichever of those two layouts the image accesses do not. Use of non-attachment aspects in this case is only well defined if the attachment is used in the subpass where the non-attachment access is being made, or the layout of the image subresource is constant throughout the entire render pass instance, including the initialLayout and finalLayout.

Note
These restrictions mean that the render pass has full knowledge of all uses of all of the attachments, so that the implementation is able to make correct decisions about when and how to perform layout transitions, when to overlap execution of subpasses, etc.

It is legal for a subpass to use no color or depth/stencil attachments, either because it has no
attachment references or because all of them are VK_ATTACHMENT_UNUSED. This kind of subpass can use shader side effects such as image stores and atomics to produce an output. In this case, the subpass continues to use the width, height, and layers of the framebuffer to define the dimensions of the rendering area, and the rasterizationSamples from each pipeline's VkPipelineMultisampleStateCreateInfo to define the number of samples used in rasterization; however, if VkPhysicalDeviceFeatures::variableMultisampleRate is VK_FALSE, then all pipelines to be bound with the subpass must have the same value for VkPipelineMultisampleStateCreateInfo ::rasterizationSamples.
Valid Usage

- attachmentCount must be equal to the attachment count specified in renderPass

- If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, and attachmentCount is not 0, pAttachments must be a valid pointer to an array of attachmentCount valid VkImageView handles

- If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, each element of pAttachments that is used as a color attachment or resolve attachment by renderPass must have been created with a usage value including VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT

- If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, each element of pAttachments that is used as a depth/stencil attachment by renderPass must have been created with a usage value including VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT

- If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, each element of pAttachments that is used as an input attachment by renderPass must have been created with a usage value including VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT

- Each element of pAttachments that is used as a fragment density map attachment by renderPass must not have been created with a flags value including VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT

- If renderPass has a fragment density map attachment and non-subsample image feature is not enabled, each element of pAttachments must have been created with a flags value including VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT unless that element is the fragment density map attachment

- If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, each element of pAttachments must have been created with a VkFormat value that matches the VkFormat specified by the corresponding VkAttachmentDescription in renderPass

- If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, each element of pAttachments must have been created with a samples value that matches the samples value specified by the corresponding VkAttachmentDescription in renderPass

- If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, each element of pAttachments must have dimensions at least as large as the corresponding framebuffer dimension except for any element that is referenced by fragmentDensityMapAttachment

- If renderPass was specified with non-zero view masks, each element of pAttachments that is not referenced by fragmentDensityMapAttachment must have a layerCount greater than the index of the most significant bit set in any of those view masks

- If renderPass was specified with non-zero view masks, each element of pAttachments that is referenced by fragmentDensityMapAttachment must have a layerCount equal to 1 or greater than the index of the most significant bit set in any of those view masks

- If renderPass was not specified with non-zero view masks, each element of pAttachments that is referenced by fragmentDensityMapAttachment must have a layerCount equal to 1
• If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, an element of pAttachments that is referenced by fragmentDensityMapAttachment must have a width at least as large as \[
\frac{\text{maxFragmentDensityTexelSize.width}}{\text{width}}
\]
• If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, an element of pAttachments that is referenced by fragmentDensityMapAttachment must have a height at least as large as \[
\frac{\text{maxFragmentDensityTexelSize.height}}{\text{height}}
\]
• If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, each element of pAttachments must only specify a single mip level
• If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, each element of pAttachments must have been created with the identity swizzle
  * width must be greater than 0
  * height must be less than or equal to VkPhysicalDeviceLimits::maxFramebufferWidth
  * height must be greater than 0
  * layers must be greater than 0
  * layers must be less than or equal to VkPhysicalDeviceLimits::maxFramebufferLayers
• If renderPass was specified with non-zero view masks, layers must be 1
• If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, each element of pAttachments that is a 2D or 2D array image view taken from a 3D image must not be a depth/stencil format
• If flags does not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, and attachmentCount is not 0, pAttachments must be a valid pointer to an array of attachmentCount valid VkImageView handles
• If the imageless framebuffer feature is not enabled, flags must not include VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT
• If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the pNext chain must include a VkFramebufferAttachmentsCreateInfo structure
• If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the attachmentImageInfoCount member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain must be equal to either zero or attachmentCount
• If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the width member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain must be greater than or equal to width, except for any element that is referenced by VkRenderPassFragmentDensityMapCreateInfoEXT ::fragmentDensityMapAttachment in renderPass
• If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the height member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain must be greater than or equal to height, except for any element that is referenced by VkRenderPassFragmentDensityMapCreateInfoEXT ::fragmentDensityMapAttachment in renderPass
• If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the width member of any element
of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain that is referenced by VkRenderPassFragmentDensityMapCreateInfoEXT::fragmentDensityMapAttachment in renderPass must be greater than or equal to \[ \frac{\text{width}}{\text{width}} \]

- If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the height member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain that is referenced by VkRenderPassFragmentDensityMapCreateInfoEXT::fragmentDensityMapAttachment in renderPass must be greater than or equal to \[ \frac{\text{height}}{\text{height}} \]

- If multiview is enabled for renderPass, and flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the layerCount member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain must be greater than the maximum bit index set in the view mask in the subpasses in which it is used in renderPass

- If multiview is not enabled for renderPass, and flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the layerCount member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain must be greater than or equal to layers

- If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the layerCount member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain must be greater than or equal to layers

- If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the usage member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain that refers to an attachment used as a color attachment or resolve attachment by renderPass must include VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT

- If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the usage member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain that refers to an attachment used as a depth/stencil attachment by renderPass must include VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT

- If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the usage member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain that refers to an attachment used as a depth/stencil resolve attachment by renderPass must include VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT

- If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, the usage member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain that refers to an attachment used as an input attachment by renderPass must include VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT

- If flags includes VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT, at least one element of the pViewFormats member of any element of the pAttachmentImageInfos member of a VkFramebufferAttachmentsCreateInfo structure included in the pNext chain must be equal to the corresponding value of VkAttachmentDescription::format used to create renderPass
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_FRAMEBUFFER_CREATE_INFO`
- **pNext** must be `NULL` or a pointer to a valid instance of `VkFramebufferAttachmentsCreateInfo`
- The **sType** value of each struct in the **pNext** chain must be unique
- **flags** must be a valid combination of `VkFramebufferCreateFlagBits` values
- **renderPass** must be a valid `VkRenderPass` handle
- Both of **renderPass**, and the elements of **pAttachments** that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`

The `VkFramebufferAttachmentsCreateInfo` structure is defined as:

```c
typedef struct VkFramebufferAttachmentsCreateInfo {
    VkStructureType sType;
    const void* pNext;
    uint32_t attachmentImageInfoCount;
    const VkFramebufferAttachmentImageInfo* pAttachmentImageInfos;
} VkFramebufferAttachmentsCreateInfo;
```

or the equivalent

```c
typedef VkFramebufferAttachmentsCreateInfo VkFramebufferAttachmentsCreateInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **attachmentImageInfoCount** is the number of attachments being described.
- **pAttachmentImageInfos** is a pointer to an array of `VkFramebufferAttachmentImageInfo` instances, each of which describes a number of parameters of the corresponding attachment in a render pass instance.

Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_FRAMEBUFFER.Attachments_CREATE_INFO`
- If **attachmentImageInfoCount** is not `0`, **pAttachmentImageInfos** must be a valid pointer to an array of **attachmentImageInfoCount** valid `VkFramebufferAttachmentImageInfo` structures

The `VkFramebufferAttachmentImageInfo` structure is defined as:
typedef struct VkFramebufferAttachmentImageInfo {
    VkStructureType       sType;
    const void*           pNext;
    VkImageCreateFlags    flags;
    VkImageUsageFlags     usage;
    uint32_t              width;
    uint32_t              height;
    uint32_t              layerCount;
    uint32_t              viewFormatCount;
    const VkFormat*       pViewFormats;
} VkFramebufferAttachmentImageInfo;

or the equivalent

typedef VkFramebufferAttachmentImageInfo VkFramebufferAttachmentImageInfoKHR;

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkImageCreateFlagBits`, matching the value of `VkImageCreateInfo::flags` used to create an image that will be used with this framebuffer.
- **usage** is a bitmask of `VkImageUsageFlagBits`, matching the value of `VkImageCreateInfo::usage` used to create an image used with this framebuffer.
- **width** is the width of the image view used for rendering.
- **height** is the height of the image view used for rendering.
- **viewFormatCount** is the number of entries in the `pViewFormats` array, matching the value of `VkImageFormatListCreateInfo::viewFormatCount` used to create an image used with this framebuffer.
- **pViewFormats** is an array which lists all formats which can be used when creating views of the image, matching the value of `VkImageFormatListCreateInfo::pViewFormats` used to create an image used with this framebuffer.

Images that can be used with the framebuffer when beginning a render pass, as specified by `VkRenderPassAttachmentBeginInfo`, must be created with parameters that are identical to those specified here.
Valid Usage (Implicit)

- \textbf{sType} must be \texttt{VK_STRUCTURE_TYPE_FRAMEBUFFER_ATTACHMENT_IMAGE_INFO}
- \textbf{pNext} must be \texttt{NULL}
- \textbf{flags} must be a valid combination of \texttt{VkImageCreateFlagBits} values
- \textbf{usage} must be a valid combination of \texttt{VkImageUsageFlagBits} values
- \textbf{usage} must not be \texttt{0}
- If \texttt{viewFormatCount} is not \texttt{0}, \textbf{pViewFormats} must be a valid pointer to an array of \texttt{viewFormatCount} valid \texttt{VkFormat} values

Bits which \textbf{can} be set in \texttt{VkFramebufferCreateInfo::flags} to specify options for framebuffers are:

\begin{verbatim}
typedef enum VkFramebufferCreateFlagBits {
    VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT = 0x00000001,
    VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT_KHR = VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT,
} VkFramebufferCreateFlagBits;
\end{verbatim}

- \texttt{VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT} specifies that image views are not specified, and only attachment compatibility information will be provided via a \texttt{VkFramebufferAttachmentImageInfo} structure.

\begin{verbatim}
typedef VkFlags VkFramebufferCreateFlags;
\end{verbatim}

\texttt{VkFramebufferCreateFlags} is a bitmask type for setting a mask of zero or more \texttt{VkFramebufferCreateFlagBits}.

To destroy a framebuffer, call:

\begin{verbatim}
void vkDestroyFramebuffer(
    VkDevice device,
    VkFramebuffer framebuffer,
    const VkAllocationCallbacks* pAllocator);
\end{verbatim}

- \texttt{device} is the logical device that destroys the framebuffer.
- \texttt{framebuffer} is the handle of the framebuffer to destroy.
- \texttt{pAllocator} controls host memory allocation as described in the \texttt{Memory Allocation} chapter.
Valid Usage

- All submitted commands that refer to framebuffer must have completed execution
- If VkAllocationCallbacks were provided when framebuffer was created, a compatible set of callbacks must be provided here
- If no VkAllocationCallbacks were provided when framebuffer was created, pAllocator must be NULL

Valid Usage (Implicit)

- device must be a valid VkDevice handle
- If framebuffer is not VK_NULL_HANDLE, framebuffer must be a valid VkFramebuffer handle
- If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure
- If framebuffer is a valid handle, it must have been created, allocated, or retrieved from device

Host Synchronization

- Host access to framebuffer must be externally synchronized

7.4. Render Pass Commands

An application records the commands for a render pass instance one subpass at a time, by beginning a render pass instance, iterating over the subpasses to record commands for that subpass, and then ending the render pass instance.

To begin a render pass instance, call:

```c
void vkCmdBeginRenderPass(
    VkCommandBuffer commandBuffer,
    const VkRenderPassBeginInfo* pRenderPassBegin,
    VkSubpassContents contents);
```

- commandBuffer is the command buffer in which to record the command.
- pRenderPassBegin is a pointer to a VkRenderPassBeginInfo structure specifying the render pass to begin an instance of, and the framebuffer the instance uses.
- contents is a VkSubpassContents value specifying how the commands in the first subpass will be provided.
After beginning a render pass instance, the command buffer is ready to record the commands for the first subpass of that render pass.
Valid Usage

• If any of the *initialLayout* or *finalLayout* member of the `VkAttachmentDescription` structures or the *layout* member of the `VkAttachmentReference` structures specified when creating the render pass specified in the `renderPass` member of `pRenderPassBegin` is `VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL` then the corresponding attachment image view of the framebuffer specified in the `framebuffer` member of `pRenderPassBegin` must have been created with a usage value including `VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT`

• If any of the *initialLayout* or *finalLayout* member of the `VkAttachmentDescription` structures or the *layout* member of the `VkAttachmentReference` structures specified when creating the render pass specified in the `renderPass` member of `pRenderPassBegin` is `VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL`, `VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL`, or `VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL` then the corresponding attachment image view of the framebuffer specified in the `framebuffer` member of `pRenderPassBegin` must have been created with a usage value including `VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT`

• If any of the *initialLayout* or *finalLayout* member of the `VkAttachmentDescription` structures or the *layout* member of the `VkAttachmentReference` structures specified when creating the render pass specified in the `renderPass` member of `pRenderPassBegin` is `VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL`, or `VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL`, `VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL`, or `VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL` then the corresponding attachment image view of the framebuffer specified in the `framebuffer` member of `pRenderPassBegin` must have been created with a usage value including `VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT`

• If any of the *initialLayout* or *finalLayout* member of the `VkAttachmentDescription` structures or the *layout* member of the `VkAttachmentReference` structures specified when creating the render pass specified in the `renderPass` member of `pRenderPassBegin` is `VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL` then the corresponding attachment image view of the framebuffer specified in the `framebuffer` member of `pRenderPassBegin` must have been created with a usage value including `VK_IMAGE_USAGE_SAMPLED_BIT` or `VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT`

• If any of the *initialLayout* or *finalLayout* member of the `VkAttachmentDescription` structures or the *layout* member of the `VkAttachmentReference` structures specified when creating the render pass specified in the `renderPass` member of `pRenderPassBegin` is
then the corresponding attachment image view of the framebuffer specified in the `framebuffer` member of `pRenderPassBegin` must have been created with a `usage` value including `VK_IMAGE_USAGE_TRANSFER_SRC_BIT`.

- If any of the `initialLayout` or `finalLayout` member of the `VkAttachmentDescription` structures or the `layout` member of the `VkAttachmentReference` structures specified when creating the render pass specified in the `renderPass` member of `pRenderPassBegin` is `VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL` then the corresponding attachment image view of the framebuffer specified in the `framebuffer` member of `pRenderPassBegin` must have been created with a `usage` value including `VK_IMAGE_USAGE_TRANSFER_DST_BIT`.

- If any of the `initialLayout` members of the `VkAttachmentDescription` structures specified when creating the render pass specified in the `renderPass` member of `pRenderPassBegin` is not `VK_IMAGE_LAYOUT_UNDEFINED`, then each such `initialLayout` must be equal to the current layout of the corresponding attachment image subresource of the framebuffer specified in the `framebuffer` member of `pRenderPassBegin`.

- The `srcStageMask` and `dstStageMask` members of any element of the `pDependencies` member of `VkRenderPassCreateInfo` used to create `renderPass` must be supported by the capabilities of the queue family identified by the `queueFamilyIndex` member of the `VkCommandPoolCreateInfo` used to create the command pool which `commandBuffer` was allocated from.

- For any attachment in `framebuffer` that is used by `renderPass` and is bound to memory locations that are also bound to another attachment used by `renderPass`, and if at least one of those uses causes either attachment to be written to, both attachments must have had the `VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT` set.

### Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle.
- `pRenderPassBegin` must be a valid pointer to a valid `VkRenderPassBeginInfo` structure.
- `contents` must be a valid `VkSubpassContents` value.
- `commandBuffer` must be in the `recording state`.
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics operations.
- This command must only be called outside of a render pass instance.
- `commandBuffer` must be a primary `VkCommandBuffer`.

### Host Synchronization

- Host access to `commandBuffer` must be externally synchronized.
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized.
Alternatively to begin a render pass, call:

```c
void vkCmdBeginRenderPass2(
    VkCommandBuffer commandBuffer,
    const VkRenderPassBeginInfo* pRenderPassBegin,
    const VkSubpassBeginInfo* pSubpassBeginInfo);
```

```c
void vkCmdBeginRenderPass2KHR(
    VkCommandBuffer commandBuffer,
    const VkRenderPassBeginInfo* pRenderPassBegin,
    const VkSubpassBeginInfo* pSubpassBeginInfo);
```

- `commandBuffer` is the command buffer in which to record the command.
- `pRenderPassBegin` is a pointer to a `VkRenderPassBeginInfo` structure specifying the render pass to begin an instance of, and the framebuffer the instance uses.
- `pSubpassBeginInfo` is a pointer to a `VkSubpassBeginInfo` structure containing information about the subpass which is about to begin rendering.

After beginning a render pass instance, the command buffer is ready to record the commands for the first subpass of that render pass.
Valid Usage

- Both the framebuffer and renderPass members of pRenderPassBegin must have been created on the same VkDevice that commandBuffer was allocated on.

- If any of the initialLayout or finalLayout member of the VkAttachmentDescription structures or the layout member of the VkAttachmentReference structures specified when creating the render pass specified in the renderPass member of pRenderPassBegin is VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL then the corresponding attachment image view of the framebuffer specified in the framebuffer member of pRenderPassBegin must have been created with a usage value including VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT.

- If any of the initialLayout or finalLayout member of the VkAttachmentDescription structures or the layout member of the VkAttachmentReference structures specified when creating the render pass specified in the renderPass member of pRenderPassBegin is VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL, or VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL then the corresponding attachment image view of the framebuffer specified in the framebuffer member of pRenderPassBegin must have been created with a usage value including VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT.

- If any of the initialLayout or finalLayout member of the VkAttachmentDescription structures or the layout member of the VkAttachmentReference structures specified when creating the render pass specified in the renderPass member of pRenderPassBegin is VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL, or VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL, VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL, or VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL then the corresponding attachment image view of the framebuffer specified in the framebuffer member of pRenderPassBegin must have been created with a usage value including VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT.

- If any of the stencilInitialLayout or stencilFinalLayout member of the VkAttachmentDescriptionStencilLayout structures or the stencilLayout member of the VkAttachmentReferenceStencillLayout structures specified when creating the render pass specified in the renderPass member of pRenderPassBegin is VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL, or VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL then the corresponding attachment image view of the framebuffer specified in the framebuffer member of pRenderPassBegin must have been created with a usage value including VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT.

- If any of the initialLayout or finalLayout member of the VkAttachmentDescription structures or the layout member of the VkAttachmentReference structures specified when creating the render pass specified in the renderPass member of pRenderPassBegin is VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL then the corresponding attachment image view of the framebuffer specified in the framebuffer member of pRenderPassBegin must have been created with a usage value including VK_IMAGE_USAGE_SAMPLED_BIT or VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT.

- If any of the initialLayout or finalLayout member of the VkAttachmentDescription...
structures or the layout member of the VkAttachmentReference structures specified when creating the render pass specified in the renderPass member of pRenderPassBegin is VK_IMAGE_LAYOUT_TRANSFER_SRC_OPTIMAL then the corresponding attachment image view of the framebuffer specified in the framebuffer member of pRenderPassBegin must have been created with a usage value including VK_IMAGE_USAGE_TRANSFER_SRC_BIT

• If any of the initialLayout or finalLayout member of the VkAttachmentDescription structures or the layout member of the VkAttachmentReference structures specified when creating the render pass specified in the renderPass member of pRenderPassBegin is VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL then the corresponding attachment image view of the framebuffer specified in the framebuffer member of pRenderPassBegin must have been created with a usage value including VK_IMAGE_USAGE_TRANSFER_DST_BIT

• If any of the initialLayout members of the VkAttachmentDescription structures specified when creating the render pass specified in the renderPass member of pRenderPassBegin is not VK_IMAGE_LAYOUT_UNDEFINED, then each such initialLayout must be equal to the current layout of the corresponding attachment image subresource of the framebuffer specified in the framebuffer member of pRenderPassBegin

• The srcStageMask and dstStageMask members of any element of the pDependencies member of VkRenderPassCreateInfo used to create renderPass must be supported by the capabilities of the queue family identified by the queueFamilyIndex member of the VkCommandPoolCreateInfo used to create the command pool which commandBuffer was allocated from

• For any attachment in framebuffer that is used by renderPass and is bound to memory locations that are also bound to another attachment used by renderPass, and if at least one of those uses causes either attachment to be written to, both attachments must have had the VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT set

Valid Usage (Implicit)

• commandBuffer must be a valid VkCommandBuffer handle

• pRenderPassBegin must be a valid pointer to a valid VkRenderPassBeginInfo structure

• pSubpassBeginInfo must be a valid pointer to a valid VkSubpassBeginInfo structure

• commandBuffer must be in the recording state

• The VkCommandPool that commandBuffer was allocated from must support graphics operations

• This command must only be called outside of a render pass instance

• commandBuffer must be a primary VkCommandBuffer
Host Synchronization

- Host access to `commandBuffer` must be externally synchronized.
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized.

The `VkRenderPassBeginInfo` structure is defined as:

```c
typedef struct VkRenderPassBeginInfo {
    VkStructureType sType;
    const void* pNext;
    VkRenderPass renderPass;
    VkFramebuffer framebuffer;
    VkRect2D renderArea;
    uint32_t clearValueCount;
    const VkClearValue* pClearValues;
} VkRenderPassBeginInfo;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `renderPass` is the render pass to begin an instance of.
- `framebuffer` is the framebuffer containing the attachments that are used with the render pass.
- `renderArea` is the render area that is affected by the render pass instance, and is described in more detail below.
- `clearValueCount` is the number of elements in `pClearValues`.
- `pClearValues` is a pointer to an array of `clearValueCount` `VkClearValue` structures that contains clear values for each attachment, if the attachment uses a `loadOp` value of `VK_ATTACHMENT_LOAD_OP_CLEAR` or if the attachment has a depth/stencil format and uses a `stencilLoadOp` value of `VK_ATTACHMENT_LOAD_OP_CLEAR`. The array is indexed by attachment number. Only elements corresponding to cleared attachments are used. Other elements of `pClearValues` are ignored.

`renderArea` is the render area that is affected by the render pass instance. The effects of attachment load, store and multisample resolve operations are restricted to the pixels whose x and y coordinates fall within the render area on all attachments. The render area extends to all layers of `framebuffer`. The application must ensure (using scissor if necessary) that all rendering is contained...
within the render area. The render area, after any transform specified by `VkRenderPassTransformBeginInfoQCOM::transform` is applied, **must** be contained within the framebuffer dimensions.

If **render pass transform** is enabled, then `renderArea` **must** equal the framebuffer pre-transformed dimensions. After `renderArea` has been transformed by `VkRenderPassTransformBeginInfoQCOM::transform`, the resulting render area **must** be equal to the framebuffer dimensions.

When multiview is enabled, the resolve operation at the end of a subpass applies to all views in the view mask.

**Note**

There **may** be a performance cost for using a render area smaller than the framebuffer, unless it matches the render area granularity for the render pass.
Valid Usage

- `clearValueCount` must be greater than the largest attachment index in `renderPass` that specifies a loadOp (or `stencilLoadOp`, if the attachment has a depth/stencil format) of `VK_ATTACHMENT_LOAD_OP_CLEAR`.

- `renderPass` must be compatible with the `renderPass` member of the `VkFramebufferCreateInfo` structure specified when creating `framebuffer`.

- If the `pNext` chain does not contain `VkDeviceGroupRenderPassBeginInfo` or its `deviceRenderAreaCount` member is equal to 0, `renderArea.offset.x` must be greater than or equal to 0.

- If the `pNext` chain does not contain `VkDeviceGroupRenderPassBeginInfo` or its `deviceRenderAreaCount` member is equal to 0, `renderArea.offset.y` must be greater than or equal to 0.

- If the `pNext` chain does not contain `VkDeviceGroupRenderPassBeginInfo` or its `deviceRenderAreaCount` member is equal to 0, `renderArea.offset.x + renderArea.offset.width` must be less than or equal to `VkFramebufferCreateInfo::width` the `framebuffer` was created with.

- If the `pNext` chain does not contain `VkDeviceGroupRenderPassBeginInfo` or its `deviceRenderAreaCount` member is equal to 0, `renderArea.offset.y + renderArea.offset.height` must be less than or equal to `VkFramebufferCreateInfo::height` the `framebuffer` was created with.

- If the `pNext` chain contains `VkDeviceGroupRenderPassBeginInfo`, the `offset.x` member of each element of `pDeviceRenderAreas` must be greater than or equal to 0.

- If the `pNext` chain contains `VkDeviceGroupRenderPassBeginInfo`, the `offset.y` member of each element of `pDeviceRenderAreas` must be greater than or equal to 0.

- If the `pNext` chain contains `VkDeviceGroupRenderPassBeginInfo`, `offset.x + offset.width` of each element of `pDeviceRenderAreas` must be less than or equal to `VkFramebufferCreateInfo::width` the `framebuffer` was created with.

- If the `pNext` chain contains `VkDeviceGroupRenderPassBeginInfo`, `offset.y + offset.height` of each element of `pDeviceRenderAreas` must be less than or equal to `VkFramebufferCreateInfo::height` the `framebuffer` was created with.

- If `framebuffer` was created with a `VkFramebufferCreateInfo::flags` value that did not include `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, and the `pNext` chain includes a `VkRenderPassAttachmentBeginInfo` structure, its `attachmentCount` must be zero.

- If `framebuffer` was created with a `VkFramebufferCreateInfo::flags` value that included `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, the `attachmentCount` of a `VkRenderPassAttachmentBeginInfo` structure included in the `pNext` chain must be equal to the value of `VkFramebufferAttachmentsCreateInfo::attachmentImageInfoCount` used to create `framebuffer`.

- If `framebuffer` was created with a `VkFramebufferCreateInfo::flags` value that included `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT_KHR`, each element of the `pAttachments` member of a `VkRenderPassAttachmentBeginInfo` structure included in the `pNext` chain must have been created on the same `VkDevice` as `framebuffer` and `renderPass`.
• If framebuffer was created with a `VkFramebufferCreateInfo::flags` value that included `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, each element of the `pAttachments` member of a `VkRenderPassAttachmentBeginInfo` structure included in the `pNext` chain must be a `VkImageView` of an image created with a value of `VkImageCreateInfo::flags` equal to the `flags` member of the corresponding element of `VkFramebufferAttachmentsCreateInfoKHR::pAttachments` used to create framebuffer.

• If framebuffer was created with a `VkFramebufferCreateInfo::flags` value that included `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, each element of the `pAttachments` member of a `VkRenderPassAttachmentBeginInfo` structure included in the `pNext` chain must be a `VkImageView` of an image created with a value of `VkImageCreateInfo::usage` equal to the `usage` member of the corresponding element of `VkFramebufferAttachmentsCreateInfo::pAttachments` used to create framebuffer.

• If framebuffer was created with a `VkFramebufferCreateInfo::flags` value that included `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, each element of the `pAttachments` member of a `VkRenderPassAttachmentBeginInfo` structure included in the `pNext` chain must be a `VkImageView` with a width equal to the `width` member of the corresponding element of `VkFramebufferAttachmentsCreateInfoKHR::pAttachments` used to create framebuffer.

• If framebuffer was created with a `VkFramebufferCreateInfo::flags` value that included `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, each element of the `pAttachments` member of a `VkRenderPassAttachmentBeginInfo` structure included in the `pNext` chain must be a `VkImageView` with a height equal to the `height` member of the corresponding element of `VkFramebufferAttachmentsCreateInfo::pAttachments` used to create framebuffer.

• If framebuffer was created with a `VkFramebufferCreateInfo::flags` value that included `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, each element of the `pAttachments` member of a `VkRenderPassAttachmentBeginInfo` structure included in the `pNext` chain must be a `VkImageView` of an image created with a value of `VkImageViewCreateInfo::subresourceRange.layerCount` equal to the `layerCount` member of the corresponding element of `VkFramebufferAttachmentsCreateInfoKHR::pAttachments` used to create framebuffer.

• If framebuffer was created with a `VkFramebufferCreateInfo::flags` value that included `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, each element of the `pAttachments` member of a `VkRenderPassAttachmentBeginInfo` structure included in the `pNext` chain must be a `VkImageView` of an image created with a set of elements in `VkImageFormatListCreateInfo::pViewFormats` equal to the set of elements in the `pViewFormats` member of the corresponding element of `VkFramebufferAttachmentsCreateInfoKHR::pAttachments` used to create framebuffer.

• If framebuffer was created with a `VkFramebufferCreateInfo::flags` value that included `VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT`, each element of the `pAttachments` member of a `VkRenderPassAttachmentBeginInfo` structure included in the `pNext` chain must be a `VkImageView` of an image created with a value of `VkImageViewCreateInfo::format` equal...
to the corresponding value of \texttt{VkAttachmentDescription::format} in \texttt{renderPass}.

- If \textit{framebuffer} was created with a \texttt{VkFramebufferCreateInfo::flags} value that included \texttt{VK_FRAMEBUFFER_CREATE_IMAGELESS_BIT}, each element of the \texttt{pAttachments} member of a \texttt{VkRenderPassAttachmentBeginInfo} structure included in the \texttt{pNext} chain must be a \texttt{VkImageView} of an image created with a value of \texttt{VkImageCreateInfo::samples} equal to the corresponding value of \texttt{VkAttachmentDescription::samples} in \texttt{renderPass}.

- If the \texttt{pNext} chain includes \texttt{VkRenderPassTransformBeginInfoQCOM}, \texttt{renderArea::offset} must equal (0,0).

- If the \texttt{pNext} chain includes \texttt{VkRenderPassTransformBeginInfoQCOM}, \texttt{renderArea::extent} transformed by \texttt{VkRenderPassTransformBeginInfoQCOM::transform} must equal the \texttt{framebuffer} dimensions.

### Valid Usage (Implicit)

- \texttt{sType} must be \texttt{VK_STRUCTURE_TYPE_RENDER_PASS_BEGIN_INFO}.

- Each \texttt{pNext} member of any structure (including this one) in the \texttt{pNext} chain must be either \texttt{NULL} or a pointer to a valid instance of \texttt{VkDeviceGroupRenderPassBeginInfo}, \texttt{VkRenderPassAttachmentBeginInfo}, \texttt{VkRenderPassSampleLocationsBeginInfoEXT}, or \texttt{VkRenderPassTransformBeginInfoQCOM}.

- The \texttt{sType} value of each struct in the \texttt{pNext} chain must be unique.

- \texttt{renderPass} must be a valid \texttt{VkRenderPass} handle.

- \texttt{framebuffer} must be a valid \texttt{VkFramebuffer} handle.

- If \texttt{clearValueCount} is not 0, \texttt{pClearValues} must be a valid pointer to an array of \texttt{clearValueCount} \texttt{VkClearValue} unions.

- Both of \texttt{framebuffer}, and \texttt{renderPass} must have been created, allocated, or retrieved from the same \texttt{VkDevice}.

The image layout of the depth aspect of a depth/stencil attachment referring to an image created with \texttt{VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT} is dependent on the last sample locations used to render to the image subresource, thus preserving the contents of such depth/stencil attachments across subpass boundaries requires the application to specify these sample locations whenever a layout transition of the attachment may occur. This information can be provided by adding a \texttt{VkRenderPassSampleLocationsBeginInfoEXT} structure to the \texttt{pNext} chain of \texttt{VkRenderPassBeginInfo}.

The \texttt{VkRenderPassSampleLocationsBeginInfoEXT} structure is defined as:
typedef struct VkRenderPassSampleLocationsBeginInfoEXT {
    VkStructureType                          sType;
    const void*                              pNext;
    uint32_t                                 attachmentInitialSampleLocationsCount;
    const VkAttachmentSampleLocationsEXT*    pAttachmentInitialSampleLocations;
    uint32_t                                 postSubpassSampleLocationsCount;
    const VkSubpassSampleLocationsEXT*       pPostSubpassSampleLocations;
} VkRenderPassSampleLocationsBeginInfoEXT;

• **sType** is the type of this structure.

• **pNext** is **NULL** or a pointer to an extension-specific structure.

• **attachmentInitialSampleLocationsCount** is the number of elements in the
  **pAttachmentInitialSampleLocations** array.

• **pAttachmentInitialSampleLocations** is a pointer to an array of
  **attachmentInitialSampleLocationsCount** **VkAttachmentSampleLocationsEXT** structures
  specifying the attachment indices and their corresponding sample location state.
  Each element of **pAttachmentInitialSampleLocations** can specify the sample location state to use in
  the automatic layout transition performed to transition a depth/stencil attachment
  from the initial layout of the attachment to the image layout specified for the attachment
  in the first subpass using it.

• **postSubpassSampleLocationsCount** is the number of elements in the **pPostSubpassSampleLocations**
  array.

• **pPostSubpassSampleLocations** is a pointer to an array of **postSubpassSampleLocationsCount**
  **VkSubpassSampleLocationsEXT** structures specifying the subpass indices and their
  corresponding sample location state. Each element of **pPostSubpassSampleLocations** can specify
  the sample location state to use in the automatic layout transition performed to transition
  the depth/stencil attachment used by the specified subpass to the image layout
  specified in a dependent subpass or to the final layout of the attachment in case
  the specified subpass is the last subpass using that attachment.

  In addition, if **VkPhysicalDeviceSampleLocationsPropertiesEXT::variableSampleLocations** is **VK_FALSE**, each
  element of **pPostSubpassSampleLocations** must specify the sample location state that matches the
  sample locations used by all pipelines that will be bound to a command buffer during
  the specified subpass. If **variableSampleLocations** is **VK_TRUE**, the sample locations used for
  rasterization do not depend on **pPostSubpassSampleLocations**.
Valid Usage (Implicit)

- **sType** must be VK_STRUCTURE_TYPE_RENDER_PASS_SAMPLE_LOCATIONS_BEGIN_INFO_EXT

- If `attachmentInitialSampleLocationsCount` is not 0, `pAttachmentInitialSampleLocations` must be a valid pointer to an array of `attachmentInitialSampleLocationsCount` valid `VkAttachmentSampleLocationsEXT` structures

- If `postSubpassSampleLocationsCount` is not 0, `pPostSubpassSampleLocations` must be a valid pointer to an array of `postSubpassSampleLocationsCount` valid `VkSubpassSampleLocationsEXT` structures

The `VkAttachmentSampleLocationsEXT` structure is defined as:

```c
typedef struct VkAttachmentSampleLocationsEXT {
    uint32_t attachmentIndex;
    VkSampleLocationsInfoEXT sampleLocationsInfo;
} VkAttachmentSampleLocationsEXT;
```

- `attachmentIndex` is the index of the attachment for which the sample locations state is provided.
- `sampleLocationsInfo` is the sample locations state to use for the layout transition of the given attachment from the initial layout of the attachment to the image layout specified for the attachment in the first subpass using it.

If the image referenced by the framebuffer attachment at index `attachmentIndex` was not created with VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT then the values specified in `sampleLocationsInfo` are ignored.

Valid Usage

- `attachmentIndex` must be less than the `attachmentCount` specified in `VkRenderPassCreateInfo` the render pass specified by `VkRenderPassBeginInfo::renderPass` was created with

Valid Usage (Implicit)

- `sampleLocationsInfo` must be a valid `VkSampleLocationsInfoEXT` structure

The `VkSubpassSampleLocationsEXT` structure is defined as:

```c
typedef struct VkSubpassSampleLocationsEXT {
    uint32_t subpassIndex;
    VkSampleLocationsInfoEXT sampleLocationsInfo;
} VkSubpassSampleLocationsEXT;
```
- `subpassIndex` is the index of the subpass for which the sample locations state is provided.
- `sampleLocationsInfo` is the sample locations state to use for the layout transition of the depth/stencil attachment away from the image layout the attachment is used with in the subpass specified in `subpassIndex`.

If the image referenced by the depth/stencil attachment used in the subpass identified by `subpassIndex` was not created with `VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT` or if the subpass does not use a depth/stencil attachment, and `VkPhysicalDeviceSampleLocationsPropertiesEXT::variableSampleLocations` is `VK_TRUE` then the values specified in `sampleLocationsInfo` are ignored.

### Valid Usage

- `subpassIndex` must be less than the `subpassCount` specified in `VkRenderPassCreateInfo` the render pass specified by `VkRenderPassBeginInfo::renderPass` was created with.

### Valid Usage (Implicit)

- `sampleLocationsInfo` must be a valid `VkSampleLocationsInfoEXT` structure.

To begin a renderpass instance with render pass transform enabled, add the `VkRenderPassTransformBeginInfoQCOM` to the `pNext` chain of `VkRenderPassBeginInfo` structure passed to the `vkCmdBeginRenderPass` command specifying the renderpass transform.

The `VkRenderPassTransformBeginInfoQCOM` structure is defined as:

```c
typedef struct VkRenderPassTransformBeginInfoQCOM {
    VkStructureType sType;
    void* pNext;
    VkSurfaceTransformFlagBitsKHR transform;
} VkRenderPassTransformBeginInfoQCOM;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `transform` is a `VkSurfaceTransformFlagBitsKHR` value describing the transform to be applied to rasterization.
Valid Usage

- `transform` must be `VK_SURFACE_TRANSFORM_IDENTITY_BIT_KHR`, `VK_SURFACE_TRANSFORM_ROTATE_90_BIT_KHR`, `VK_SURFACE_TRANSFORM_ROTATE_180_BIT_KHR`, or `VK_SURFACE_TRANSFORM_ROTATE_270_BIT_KHR`.
- The `renderpass` must have been created with `VkRenderPassCreateInfo::flags` containing `VK_READER_PASS_CREATE_TRANSFORM_BIT_QCOM`.

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_RENDER_PASS_TRANSFORM_BEGIN_INFO_QCOM`.

The `VkSubpassBeginInfo` structure is defined as:

```c
typedef struct VkSubpassBeginInfo {
    VkStructureType sType;
    const void*     pNext;
    VkSubpassContents contents;
} VkSubpassBeginInfo;
```

or the equivalent

```c
typedef VkSubpassBeginInfo VkSubpassBeginInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `contents` is a `VkSubpassContents` value specifying how the commands in the next subpass will be provided.

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_SUBPASS_BEGIN_INFO`.
- `pNext` must be `NULL`.
- `contents` must be a valid `VkSubpassContents` value.

Possible values of `vkCmdBeginRenderPass::contents`, specifying how the commands in the first subpass will be provided, are:
typedef enum VkSubpassContents {
    VK_SUBPASS_CONTENTS_INLINE = 0,
    VK_SUBPASS_CONTENTS_SECONDARY_COMMAND BUFFERS = 1,
} VkSubpassContents;

- **VK_SUBPASS_CONTENTS_INLINE** specifies that the contents of the subpass will be recorded inline in the primary command buffer, and secondary command buffers must not be executed within the subpass.

- **VK_SUBPASS_CONTENTS_SECONDARY_COMMAND_BUFFERS** specifies that the contents are recorded in secondary command buffers that will be called from the primary command buffer, and `vkCmdExecuteCommands` is the only valid command on the command buffer until `vkCmdNextSubpass` or `vkCmdEndRenderPass`.

If the `pNext` chain of `VkRenderPassBeginInfo` includes a `VkDeviceGroupRenderPassBeginInfo` structure, then that structure includes a device mask and set of render areas for the render pass instance.

The `VkDeviceGroupRenderPassBeginInfo` structure is defined as:

```c
typedef struct VkDeviceGroupRenderPassBeginInfo {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           deviceMask;
    uint32_t           deviceRenderAreaCount;
    const VkRect2D*    pDeviceRenderAreas;
} VkDeviceGroupRenderPassBeginInfo;
```

or the equivalent

```c
typedef VkDeviceGroupRenderPassBeginInfo VkDeviceGroupRenderPassBeginInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **deviceMask** is the device mask for the render pass instance.
- **deviceRenderAreaCount** is the number of elements in the `pDeviceRenderAreas` array.
- **pDeviceRenderAreas** is a pointer to an array of `VkRect2D` structures defining the render area for each physical device.

The **deviceMask** serves several purposes. It is an upper bound on the set of physical devices that can be used during the render pass instance, and the initial device mask when the render pass instance begins. In addition, commands transitioning to the next subpass in the render pass instance and commands ending the render pass instance, and, accordingly render pass attachment load, store, and resolve operations and subpass dependencies corresponding to the render pass instance, are executed on the physical devices included in the device mask provided here.
If `deviceRenderAreaCount` is not zero, then the elements of `pDeviceRenderAreas` override the value of `VkRenderPassBeginInfo::renderArea`, and provide a render area specific to each physical device. These render areas serve the same purpose as `VkRenderPassBeginInfo::renderArea`, including controlling the region of attachments that are cleared by `VK_ATTACHMENT_LOAD_OP_CLEAR` and that are resolved into resolve attachments.

If this structure is not present, the render pass instance's device mask is the value of `VkDeviceGroupCommandBufferBeginInfo::deviceMask`. If this structure is not present or if `deviceRenderAreaCount` is zero, `VkRenderPassBeginInfo::renderArea` is used for all physical devices.

### Valid Usage

- `deviceMask` must be a valid device mask value
- `deviceMask` must not be zero
- `deviceMask` must be a subset of the command buffer's initial device mask
- `deviceRenderAreaCount` must either be zero or equal to the number of physical devices in the logical device

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_DEVICE_GROUP_RENDER_PASS_BEGIN_INFO`
- If `deviceRenderAreaCount` is not 0, `pDeviceRenderAreas` must be a valid pointer to an array of `deviceRenderAreaCount` `VkRect2D` structures

The `VkRenderPassAttachmentBeginInfo` structure is defined as:

```c
typedef struct VkRenderPassAttachmentBeginInfo {
    VkStructureType       sType;
    const void*           pNext;
    uint32_t              attachmentCount;
    const VkImageView*    pAttachments;
} VkRenderPassAttachmentBeginInfo;
```

or the equivalent

```c
typedef VkRenderPassAttachmentBeginInfo VkRenderPassAttachmentBeginInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `attachmentCount` is the number of attachments.
- `pAttachments` is a pointer to an array of `VkImageView` handles, each of which will be used as the corresponding attachment in the render pass instance.
Valid Usage

- Each element of `pAttachments` must only specify a single mip level
- Each element of `pAttachments` must have been created with the identity swizzle

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_RENDER_PASS_ATTACHMENT_BEGIN_INFO`
- If `attachmentCount` is not 0, `pAttachments` must be a valid pointer to an array of `attachmentCount` valid `VkImageView` handles

To query the render area granularity, call:

```c
void vkGetRenderAreaGranularity(
    VkDevice device,            // device is the logical device that owns the render pass.
    VkRenderPass renderPass,   // renderPass is a handle to a render pass.
    VkExtent2D* pGranularity); // pGranularity is a pointer to a VkExtent2D structure in which the granularity is returned.
```

The conditions leading to an optimal `renderArea` are:

- the `offset.x` member in `renderArea` is a multiple of the `width` member of the returned `VkExtent2D` (the horizontal granularity).
- the `offset.y` member in `renderArea` is a multiple of the `height` of the returned `VkExtent2D` (the vertical granularity).
- either the `offset.width` member in `renderArea` is a multiple of the horizontal granularity or `offset.x+offset.width` is equal to the `width` of the framebuffer in the `VkRenderPassBeginInfo`.
- either the `offset.height` member in `renderArea` is a multiple of the vertical granularity or `offset.y+offset.height` is equal to the `height` of the framebuffer in the `VkRenderPassBeginInfo`.

Subpass dependencies are not affected by the render area, and apply to the entire image subresources attached to the framebuffer as specified in the description of automatic layout transitions. Similarly, pipeline barriers are valid even if their effect extends outside the render area.
To transition to the next subpass in the render pass instance after recording the commands for a subpass, call:

```c
void vkCmdNextSubpass(
    VkCommandBuffer commandBuffer,
    VkSubpassContents contents);
```

- `commandBuffer` is the command buffer in which to record the command.
- `contents` specifies how the commands in the next subpass will be provided, in the same fashion as the corresponding parameter of `vkCmdBeginRenderPass`.

The subpass index for a render pass begins at zero when `vkCmdBeginRenderPass` is recorded, and increments each time `vkCmdNextSubpass` is recorded.

Moving to the next subpass automatically performs any multisample resolve operations in the subpass being ended. End-of-subpass multisample resolves are treated as color attachment writes for the purposes of synchronization. This applies to resolve operations for both color and depth/stencil attachments. That is, they are considered to execute in the `VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT` pipeline stage and their writes are synchronized with `VK_ACCESS_COLOR_ATTACHMENT_WRITE_BIT`. Synchronization between rendering within a subpass and any resolve operations at the end of the subpass occurs automatically, without need for explicit dependencies or pipeline barriers. However, if the resolve attachment is also used in a different subpass, an explicit dependency is needed.

After transitioning to the next subpass, the application can record the commands for that subpass.

**Valid Usage**

- The current subpass index must be less than the number of subpasses in the render pass minus one
- This command must not be recorded when transform feedback is active
Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `contents` must be a valid `VkSubpassContents` value
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics operations
- This command must only be called inside of a render pass instance
- `commandBuffer` must be a primary `VkCommandBuffer`

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Inside</td>
<td>Graphics</td>
<td>Graphics</td>
</tr>
</tbody>
</table>

To transition to the next subpass in the render pass instance after recording the commands for a subpass, call:

```c
void vkCmdNextSubpass2(
    VkCommandBuffer commandBuffer,
    const VkSubpassBeginInfo* pSubpassBeginInfo,
    const VkSubpassEndInfo* pSubpassEndInfo);
```

```c
void vkCmdNextSubpass2KHR(
    VkCommandBuffer commandBuffer,
    const VkSubpassBeginInfo* pSubpassBeginInfo,
    const VkSubpassEndInfo* pSubpassEndInfo);
```

- `commandBuffer` is the command buffer in which to record the command.
- `pSubpassBeginInfo` is a pointer to a `VkSubpassBeginInfo` structure containing information about the subpass which is about to begin rendering.
- `pSubpassEndInfo` is a pointer to a `VkSubpassEndInfo` structure containing information about how
the previous subpass will be ended.

`vkCmdNextSubpass2` is semantically identical to `vkCmdNextSubpass`, except that it is extensible, and that `contents` is provided as part of an extensible structure instead of as a flat parameter.

### Valid Usage

- The current subpass index **must** be less than the number of subpasses in the render pass minus one
- This command **must** not be recorded when transform feedback is active

### Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `pSubpassBeginInfo` **must** be a valid pointer to a valid `VkSubpassBeginInfo` structure
- `pSubpassEndInfo` **must** be a valid pointer to a valid `VkSubpassEndInfo` structure
- `commandBuffer` **must** be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics operations
- This command **must** only be called inside of a render pass instance
- `commandBuffer` **must** be a primary `VkCommandBuffer`

### Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized

### Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Inside</td>
<td>Graphics</td>
<td>Graphics</td>
</tr>
</tbody>
</table>

To record a command to end a render pass instance after recording the commands for the last subpass, call:

```c
void vkCmdEndRenderPass(
    VkCommandBuffer commandBuffer);
```
• `commandBuffer` is the command buffer in which to end the current render pass instance.

Ending a render pass instance performs any multisample resolve operations on the final subpass.

### Valid Usage

- The current subpass index **must** be equal to the number of subpasses in the render pass minus one
- This command **must** not be recorded when transform feedback is active

### Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `commandBuffer` **must** be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics operations
- This command **must** only be called inside of a render pass instance
- `commandBuffer` **must** be a primary `VkCommandBuffer`

### Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized

### Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Inside</td>
<td>Graphics</td>
<td>Graphics</td>
</tr>
</tbody>
</table>

To record a command to end a render pass instance after recording the commands for the last subpass, call:

```c
void vkCmdEndRenderPass2(
    VkCommandBuffer commandBuffer,
    const VkSubpassEndInfo* pSubpassEndInfo);
```
```c
void vkCmdEndRenderPass2KHR(
    VkCommandBuffer commandBuffer,
    const VkSubpassEndInfo* pSubpassEndInfo);
```

- `commandBuffer` is the command buffer in which to end the current render pass instance.
- `pSubpassEndInfo` is a pointer to a `VkSubpassEndInfo` structure containing information about how the previous subpass will be ended.

`vkCmdEndRenderPass2` is semantically identical to `vkCmdEndRenderPass`, except that it is extensible.

### Valid Usage

- The current subpass index **must** be equal to the number of subpasses in the render pass minus one.
- This command **must** not be recorded when transform feedback is active.

### Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle.
- `pSubpassEndInfo` **must** be a valid pointer to a valid `VkSubpassEndInfo` structure.
- `commandBuffer` **must** be in the recording state.
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics operations.
- This command **must** only be called inside of a render pass instance.
- `commandBuffer` **must** be a primary `VkCommandBuffer`.

### Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized.
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized.

### Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>

The `VkSubpassEndInfo` structure is defined as:

336 | Chapter 7. Render Pass
typedef struct VkSubpassEndInfo {
    VkStructureType sType;
    const void* pNext;
} VkSubpassEndInfo;

or the equivalent

typedef VkSubpassEndInfo VkSubpassEndInfoKHR;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_SUBPASS_END_INFO
• pNext must be NULL
Chapter 8. Shaders

A shader specifies programmable operations that execute for each vertex, control point, tessellated vertex, primitive, fragment, or workgroup in the corresponding stage(s) of the graphics and compute pipelines.

Graphics pipelines include vertex shader execution as a result of primitive assembly, followed, if enabled, by tessellation control and evaluation shaders operating on patches, geometry shaders, if enabled, operating on primitives, and fragment shaders, if present, operating on fragments generated by Rasterization. In this specification, vertex, tessellation control, tessellation evaluation and geometry shaders are collectively referred to as vertex processing stages and occur in the logical pipeline before rasterization. The fragment shader occurs logically after rasterization.

Only the compute shader stage is included in a compute pipeline. Compute shaders operate on compute invocations in a workgroup.

Shaders can read from input variables, and read from and write to output variables. Input and output variables can be used to transfer data between shader stages, or to allow the shader to interact with values that exist in the execution environment. Similarly, the execution environment provides constants that describe capabilities.

Shader variables are associated with execution environment-provided inputs and outputs using built-in decorations in the shader. The available decorations for each stage are documented in the following subsections.

8.1. Shader Modules

Shader modules contain shader code and one or more entry points. Shaders are selected from a shader module by specifying an entry point as part of pipeline creation. The stages of a pipeline can use shaders that come from different modules. The shader code defining a shader module must be in the SPIR-V format, as described by the Vulkan Environment for SPIR-V appendix.

Shader modules are represented by VkShaderModule handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkShaderModule)
```

To create a shader module, call:

```c
VkResult vkCreateShaderModule(  
    VkDevice device,  
    const VkShaderModuleCreateInfo* pCreateInfo,  
    const VkAllocationCallbacks* pAllocator,  
    VkShaderModule* pShaderModule);
```

- `device` is the logical device that creates the shader module.
- `pCreateInfo` is a pointer to a VkShaderModuleCreateInfo structure.
• **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.

• **pShaderModule** is a pointer to a VkShaderModule handle in which the resulting shader module object is returned.

Once a shader module has been created, any entry points it contains can be used in pipeline shader stages as described in Compute Pipelines and Graphics Pipelines.

If the shader stage fails to compile VK_ERROR_INVALID_SHADER_NV will be generated and the compile log will be reported back to the application by VK_EXT_debug_report if enabled.

### Valid Usage (Implicit)

- **device** must be a valid VkDevice handle
- **pCreateInfo** must be a valid pointer to a valid VkShaderModuleCreateInfo structure
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid VkAllocationCallbacks structure
- **pShaderModule** must be a valid pointer to a VkShaderModule handle

### Return Codes

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_INVALID_SHADER_NV

The VkShaderModuleCreateInfo structure is defined as:

```c
typedef struct VkShaderModuleCreateInfo {
    VkStructureType              sType;
    const void*                  pNext;
    VkShaderModuleCreateFlags    flags;
    size_t                        codeSize;
    const uint32_t*              pCode;
} VkShaderModuleCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **flags** is reserved for future use.
- **codeSize** is the size, in bytes, of the code pointed to by **pCode**.
pCode is a pointer to code that is used to create the shader module. The type and format of the code is determined from the content of the memory addressed by pCode.

Valid Usage

- **pCode** must point to either valid SPIR-V code, formatted and packed as described by the Khronos SPIR-V Specification or valid GLSL code which must be written to the GL_KHR_vulkan_gls1 extension specification.
- If **pCode** is a pointer to SPIR-V code, that code must adhere to the validation rules described by the Validation Rules within a Module section of the SPIR-V Environment appendix.
- If **pCode** is a pointer to GLSL code, it must be valid GLSL code written to the GL_KHR_vulkan_gls1 GLSL extension specification.
- **pCode** must declare the Shader capability for SPIR-V code.
- **pCode** must not declare any capability that is not supported by the API, as described by the Capabilities section of the SPIR-V Environment appendix.
- If **pCode** declares any of the capabilities listed as optional in the SPIR-V Environment appendix, the corresponding feature(s) must be enabled.

Valid Usage (Implicit)

- **sType** must be **VK_STRUCTURE_TYPE_SHADER_MODULE_CREATE_INFO**.
- **pNext** must be **NULL** or a pointer to a valid instance of **VkShaderModuleValidationCacheCreateInfoEXT**.
- The **sType** value of each struct in the **pNext** chain must be unique.
- **flags** must be 0.
- **pCode** must be a valid pointer to an array of **codeSize / 4 uint32_t** values.

```c
typedef VkFlags VkShaderModuleCreateFlags;
```

**VkShaderModuleCreateFlags** is a bitmask type for setting a mask, but is currently reserved for future use.

To use a **VkValidationCacheEXT** to cache shader validation results, add a **VkShaderModuleValidationCacheCreateInfoEXT** structure to the **pNext** chain of the **VkShaderModuleCreateInfo** structure, specifying the cache object to use.

The **VkShaderModuleValidationCacheCreateInfoEXT** struct is defined as:
typedef struct VkShaderModuleValidationCacheCreateInfoEXT {
    VkStructureType sType;
    const void* pNext;
    VkValidationCacheEXT validationCache;
} VkShaderModuleValidationCacheCreateInfoEXT;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `validationCache` is the validation cache object from which the results of prior validation attempts will be written, and to which new validation results for this `VkShaderModule` will be written (if not already present).

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_SHADER_MODULE_VALIDATION_CACHE_CREATE_INFO_EXT`
- `validationCache` must be a valid `VkValidationCacheEXT` handle

To destroy a shader module, call:

```c
void vkDestroyShaderModule(
    VkDevice device,
    VkShaderModule shaderModule,
    const VkAllocationCallbacks* pAllocator);
```

- `device` is the logical device that destroys the shader module.
- `shaderModule` is the handle of the shader module to destroy.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

A shader module can be destroyed while pipelines created using its shaders are still in use.

### Valid Usage

- If `VkAllocationCallbacks` were provided when `shaderModule` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `shaderModule` was created, `pAllocator` must be `NULL`
8.2. Shader Execution

At each stage of the pipeline, multiple invocations of a shader may execute simultaneously. Further, invocations of a single shader produced as the result of different commands may execute simultaneously. The relative execution order of invocations of the same shader type is undefined. Shader invocations may complete in a different order than that in which the primitives they originated from were drawn or dispatched by the application. However, fragment shader outputs are written to attachments in rasterization order.

The relative execution order of invocations of different shader types is largely undefined. However, when invoking a shader whose inputs are generated from a previous pipeline stage, the shader invocations from the previous stage are guaranteed to have executed far enough to generate input values for all required inputs.

8.3. Shader Memory Access Ordering

The order in which image or buffer memory is read or written by shaders is largely undefined. For some shader types (vertex, tessellation evaluation, and in some cases, fragment), even the number of shader invocations that may perform loads and stores is undefined.

In particular, the following rules apply:

- **Vertex** and **tessellation evaluation** shaders will be invoked at least once for each unique vertex, as defined in those sections.
- **Fragment** shaders will be invoked zero or more times, as defined in that section.
- The relative execution order of invocations of the same shader type is undefined. A store issued by a shader when working on primitive B might complete prior to a store for primitive A, even if primitive A is specified prior to primitive B. This applies even to fragment shaders; while fragment shader outputs are always written to the framebuffer in rasterization order, stores executed by fragment shader invocations are not.
The relative execution order of invocations of different shader types is largely undefined.

Note

The above limitations on shader invocation order make some forms of synchronization between shader invocations within a single set of primitives unimplementable. For example, having one invocation poll memory written by another invocation assumes that the other invocation has been launched and will complete its writes in finite time.

The Memory Model appendix defines the terminology and rules for how to correctly communicate between shader invocations, such as when a write is Visible-To a read, and what constitutes a Data Race.

Applications must not cause a data race.

8.4. Shader Inputs and Outputs

Data is passed into and out of shaders using variables with input or output storage class, respectively. User-defined inputs and outputs are connected between stages by matching their Location decorations. Additionally, data can be provided by or communicated to special functions provided by the execution environment using BuiltIn decorations.

In many cases, the same BuiltIn decoration can be used in multiple shader stages with similar meaning. The specific behavior of variables decorated as BuiltIn is documented in the following sections.

8.5. Task Shaders

Task shaders operate in conjunction with the mesh shaders to produce a collection of primitives that will be processed by subsequent stages of the graphics pipeline. Its primary purpose is to create a variable amount of subsequent mesh shader invocations.

Task shaders are invoked via the execution of the programmable mesh shading pipeline.

The task shader has no fixed-function inputs other than variables identifying the specific workgroup and invocation. The only fixed output of the task shader is a task count, identifying the number of mesh shader workgroups to create. The task shader can write additional outputs to task memory, which can be read by all of the mesh shader workgroups it created.

8.5.1. Task Shader Execution

Task workloads are formed from groups of work items called workgroups and processed by the task shader in the current graphics pipeline. A workgroup is a collection of shader invocations that execute the same shader, potentially in parallel. Task shaders execute in global workgroups which are divided into a number of local workgroups with a size that can be set by assigning a value to the LocalSize execution mode or via an object decorated by the WorkgroupSize decoration. An invocation within a local workgroup can share data with other members of the local workgroup through shared variables and issue memory and control flow barriers to synchronize with other members.
8.6. Mesh Shaders

Mesh shaders operate in workgroups to produce a collection of primitives that will be processed by subsequent stages of the graphics pipeline. Each workgroup emits zero or more output primitives and the group of vertices and their associated data required for each output primitive.

Mesh shaders are invoked via the execution of the programmable mesh shading pipeline.

The only inputs available to the mesh shader are variables identifying the specific workgroup and invocation and, if applicable, any outputs written to task memory by the task shader that spawned the mesh shader’s workgroup. The mesh shader can operate without a task shader as well.

The invocations of the mesh shader workgroup write an output mesh, comprising a set of primitives with per-primitive attributes, a set of vertices with per-vertex attributes, and an array of indices identifying the mesh vertices that belong to each primitive. The primitives of this mesh are then processed by subsequent graphics pipeline stages, where the outputs of the mesh shader form an interface with the fragment shader.

8.6.1. Mesh Shader Execution

Mesh workloads are formed from groups of work items called workgroups and processed by the mesh shader in the current graphics pipeline. A workgroup is a collection of shader invocations that execute the same shader, potentially in parallel. Mesh shaders execute in global workgroups which are divided into a number of local workgroups with a size that can be set by assigning a value to the LocalSize execution mode or via an object decorated by the WorkgroupSize decoration. An invocation within a local workgroup can share data with other members of the local workgroup through shared variables and issue memory and control flow barriers to synchronize with other members of the local workgroup.

The global workgroups may be generated explicitly via the API, or implicitly through the task shader’s work creation mechanism.

8.7. Vertex Shaders

Each vertex shader invocation operates on one vertex and its associated vertex attribute data, and outputs one vertex and associated data. Graphics pipelines using primitive shading must include a vertex shader, and the vertex shader stage is always the first shader stage in the graphics pipeline.

8.7.1. Vertex Shader Execution

A vertex shader must be executed at least once for each vertex specified by a draw command. If the subpass includes multiple views in its view mask, the shader may be invoked separately for each view. During execution, the shader is presented with the index of the vertex and instance for which it has been invoked. Input variables declared in the vertex shader are filled by the implementation with the values of vertex attributes associated with the invocation being executed.
If the same vertex is specified multiple times in a draw command (e.g. by including the same index value multiple times in an index buffer) the implementation may reuse the results of vertex shading if it can statically determine that the vertex shader invocations will produce identical results.

Note
It is implementation-dependent when and if results of vertex shading are reused, and thus how many times the vertex shader will be executed. This is true also if the vertex shader contains stores or atomic operations (see vertexPipelineStoresAndAtomics).

8.8. Tessellation Control Shaders

The tessellation control shader is used to read an input patch provided by the application and to produce an output patch. Each tessellation control shader invocation operates on an input patch (after all control points in the patch are processed by a vertex shader) and its associated data, and outputs a single control point of the output patch and its associated data, and can also output additional per-patch data. The input patch is sized according to the patchControlPoints member of VkPipelineTessellationStateCreateInfo, as part of input assembly. The size of the output patch is controlled by the OpExecutionMode OutputVertices specified in the tessellation control or tessellation evaluation shaders, which must be specified in at least one of the shaders. The size of the input and output patches must each be greater than zero and less than or equal to VkPhysicalDeviceLimits::maxTessellationPatchSize.

8.8.1. Tessellation Control Shader Execution

A tessellation control shader is invoked at least once for each output vertex in a patch. If the subpass includes multiple views in its view mask, the shader may be invoked separately for each view.

Inputs to the tessellation control shader are generated by the vertex shader. Each invocation of the tessellation control shader can read the attributes of any incoming vertices and their associated data. The invocations corresponding to a given patch execute logically in parallel, with undefined relative execution order. However, the OpControlBarrier instruction can be used to provide limited control of the execution order by synchronizing invocations within a patch, effectively dividing tessellation control shader execution into a set of phases. Tessellation control shaders will read undefined values if one invocation reads a per-vertex or per-patch attribute written by another invocation at any point during the same phase, or if two invocations attempt to write different values to the same per-patch output in a single phase.

8.9. Tessellation Evaluation Shaders

The Tessellation Evaluation Shader operates on an input patch of control points and their associated data, and a single input barycentric coordinate indicating the invocation’s relative position within the subdivided patch, and outputs a single vertex and its associated data.
8.9.1. Tessellation Evaluation Shader Execution

A tessellation evaluation shader is invoked at least once for each unique vertex generated by the tessellator. If the subpass includes multiple views in its view mask, the shader may be invoked separately for each view.

8.10. Geometry Shaders

The geometry shader operates on a group of vertices and their associated data assembled from a single input primitive, and emits zero or more output primitives and the group of vertices and their associated data required for each output primitive.

8.10.1. Geometry Shader Execution

A geometry shader is invoked at least once for each primitive produced by the tessellation stages, or at least once for each primitive generated by primitive assembly when tessellation is not in use. A shader can request that the geometry shader runs multiple instances. A geometry shader is invoked at least once for each instance. If the subpass includes multiple views in its view mask, the shader may be invoked separately for each view.

8.11. Fragment Shaders

Fragment shaders are invoked as the result of rasterization in a graphics pipeline. Each fragment shader invocation operates on a single fragment and its associated data. With few exceptions, fragment shaders do not have access to any data associated with other fragments and are considered to execute in isolation of fragment shader invocations associated with other fragments.

8.11.1. Fragment Shader Execution

Fragment shaders are invoked for each fragment generated by rasterization, or as helper invocations.

For fragment shaders invoked by fragments, the following rules apply:

- A fragment shader must not be executed if a fragment operation that executes before fragment shading discards the fragment.
- A fragment shader may not be executed if:
  - An implementation determines that another fragment shader, invoked by a subsequent primitive in primitive order, overwrites all results computed by the shader (including writes to storage resources).
  - Any other fragment operation discards the fragment, and the shader does not write to any storage resources.
- Otherwise, at least one fragment shader must be executed.
  - If sample shading is enabled and multiple invocations per fragment are required, additional invocations must be executed as specified.
  - If a shading rate image is used and multiple invocations per fragment are required,
additional invocations must be executed as specified.

- Each covered sample must be included in at least one fragment shader invocation.

**Note**

Multiple fragment shader invocations may be executed for the same fragment for any number of implementation dependent reasons. When there is more than one fragment shader invocation per fragment, the association of samples to invocations is implementation-dependent. Stores and atomics performed by these additional invocations have the normal effect.

For example, if the subpass includes multiple views in its view mask, a fragment shader may be invoked separately for each view.

Similarly, if the render pass has a fragment density map attachment, more than one fragment shader invocation may be invoked for each covered sample. Such additional invocations are only produced if VkPhysicalDeviceFragmentDensityMapPropertiesEXT::fragmentDensityInvocations is VK_TRUE. Implementations may generate these additional fragment shader invocations in order to make transitions between fragment areas with different fragment densities more smooth.

**Note**

Relative ordering of execution of different fragment shader invocations is explicitly not defined.

### 8.11.2. Early Fragment Tests

An explicit control is provided to allow fragment shaders to enable early fragment tests. If the fragment shader specifies the EarlyFragmentTests OpExecutionMode, additional per-fragment tests are performed prior to fragment shader execution.

If the fragment shader additionally specifies the PostDepthCoverage OpExecutionMode, the value of a variable decorated with the SampleMask built-in reflects the coverage after the early fragment tests. Otherwise, it reflects the coverage before the early fragment tests.

If early fragment tests are enabled, any depth value computed by the fragment shader has no effect.

### 8.11.3. Fragment Shader Interlock

In normal operation, it is possible for more than one fragment shader invocation to be executed simultaneously for the same pixel if there are overlapping primitives. If the fragmentShaderSampleInterlock, fragmentShaderPixelInterlock, or fragmentShaderShadingRateInterlock features are enabled, it is possible to define a critical section within the fragment shader that is guaranteed to not run simultaneously with another fragment shader invocation for the same sample(s) or pixel(s). It is also possible to control the relative ordering of execution of these critical sections across different fragment shader invocations.

If the FragmentShaderSampleInterlockEXT, FragmentShaderPixelInterlockEXT, or
FragmentShaderShadingRateInterlockEXT capabilities are declared in the fragment shader, the OpBeginInvocationInterlockEXT and OpEndInvocationInterlockEXT instructions must be used to delimit a critical section of fragment shader code.

To ensure each invocation of the critical section is executed in primitive order, declare one of the PixelInterlockOrderedEXT, SampleInterlockOrderedEXT, or ShadingRateInterlockOrderedEXT execution modes. If the order of execution of each invocation of the critical section does not matter, declare one of the PixelInterlockUnorderedEXT, SampleInterlockUnorderedEXT, or ShadingRateInterlockUnorderedEXT execution modes.

The PixelInterlockOrderedEXT and PixelInterlockUnorderedEXT execution modes provide mutual exclusion in the critical section for any pair of fragments corresponding to the same pixel, or pixels if the fragment covers more than one pixel. With sample shading enabled, these execution modes are treated like SampleInterlockOrderedEXT or SampleInterlockUnorderedEXT respectively.

The SampleInterlockOrderedEXT and SampleInterlockUnorderedEXT execution modes only provide mutual exclusion for pairs of fragments that both cover at least one common sample in the same pixel; these are recommended for performance if shaders use per-sample data structures. If these execution modes are used in single-sample mode they are treated like PixelInterlockOrderedEXT or PixelInterlockUnorderedEXT respectively.

The ShadingRateInterlockOrderedEXT and ShadingRateInterlockUnorderedEXT execution modes provide mutual exclusion for pairs of fragments that both have at least one common sample in the same pixel, even if none of the common samples are covered by both fragments. With sample shading enabled, these execution modes are treated like SampleInterlockOrderedEXT or SampleInterlockUnorderedEXT respectively.

8.12. Compute Shaders

Compute shaders are invoked via vkCmdDispatch and vkCmdDispatchIndirect commands. In general, they have access to similar resources as shader stages executing as part of a graphics pipeline.

Compute workloads are formed from groups of work items called workgroups and processed by the compute shader in the current compute pipeline. A workgroup is a collection of shader invocations that execute the same shader, potentially in parallel. Compute shaders execute in global workgroups which are divided into a number of local workgroups with a size that can be set by assigning a value to the LocalSize execution mode or via an object decorated by the WorkgroupSize decoration. An invocation within a local workgroup can share data with other members of the local workgroup through shared variables and issue memory and control flow barriers to synchronize with other members of the local workgroup.

8.13. Interpolation Decorations

Interpolation decorations control the behavior of attribute interpolation in the fragment shader stage. Interpolation decorations can be applied to Input storage class variables in the fragment shader stage’s interface, and control the interpolation behavior of those variables.
Inputs that could be interpolated can be decorated by at most one of the following decorations:

- **Flat**: no interpolation
- **NoPerspective**: linear interpolation (for lines and polygons)

Fragment input variables decorated with neither Flat nor NoPerspective use perspective-correct interpolation (for lines and polygons).

The presence of and type of interpolation is controlled by the above interpolation decorations as well as the auxiliary decorations Centroid and Sample.

A variable decorated with Flat will not be interpolated. Instead, it will have the same value for every fragment within a triangle. This value will come from a single provoking vertex. A variable decorated with Flat can also be decorated with Centroid or Sample, which will mean the same thing as decorating it only as Flat.

For fragment shader input variables decorated with neither Centroid nor Sample, the assigned variable may be interpolated anywhere within the fragment and a single value may be assigned to each sample within the fragment.

If a fragment shader input is decorated with Centroid, a single value may be assigned to that variable for all samples in the fragment, but that value must be interpolated to a location that lies in both the fragment and in the primitive being rendered, including any of the fragment's samples covered by the primitive. Because the location at which the variable is interpolated may be different in neighboring fragments, and derivatives may be computed by computing differences between neighboring fragments, derivatives of centroid-sampled inputs may be less accurate than those for non-centroid interpolated variables. The PostDepthCoverage execution mode does not affect the determination of the centroid location.

If a fragment shader input is decorated with Sample, a separate value must be assigned to that variable for each covered sample in the fragment, and that value must be sampled at the location of the individual sample. When rasterizationSamples is VK_SAMPLE_COUNT_1_BIT, the fragment center must be used for Centroid, Sample, and undecorated attribute interpolation.

Fragment shader inputs that are signed or unsigned integers, integer vectors, or any double-precision floating-point type must be decorated with Flat.

When the VK_AMD_shader_explicit_vertex_parameter device extension is enabled inputs can be also decorated with the CustomInterpAMD interpolation decoration, including fragment shader inputs that are signed or unsigned integers, integer vectors, or any double-precision floating-point type. Inputs decorated with CustomInterpAMD can only be accessed by the extended instruction InterpolateAtVertexAMD and allows accessing the value of the input for individual vertices of the primitive.

When the fragmentShaderBarycentric feature is enabled, inputs can be also decorated with the PerVertexNV interpolation decoration, including fragment shader inputs that are signed or unsigned integers, integer vectors, or any double-precision floating-point type. Inputs decorated with PerVertexNV can only be accessed using an extra array dimension, where the extra index identifies one of the vertices of the primitive that produced the fragment.

A ray generation shader is similar to a compute shader. Its main purpose is to execute ray tracing queries using `OpTraceRayKHR` instructions and process the results.

8.14.1. Ray Generation Shader Execution

One ray generation shader is executed per ray tracing dispatch. Its location in the shader binding table (see Shader Binding Table for details) is passed directly into `vkCmdTraceRaysKHR` using the `raygenShaderBindingTableBuffer` and `raygenShaderBindingOffset` parameters.

8.15. Intersection Shaders

Intersection shaders enable the implementation of arbitrary, application defined geometric primitives. An intersection shader for a primitive is executed whenever its axis-aligned bounding box is hit by a ray.

Like other ray tracing shader domains, an intersection shader operates on a single ray at a time. It also operates on a single primitive at a time. It is therefore the purpose of an intersection shader to compute the ray-primitive intersections and report them. To report an intersection, the shader calls the `OpReportIntersectionKHR` instruction.

An intersection shader communicates with any-hit and closest shaders by generating attribute values that they can read. Intersection shaders cannot read or modify the ray payload.

8.15.1. Intersection Shader Execution

The order in which intersections are found along a ray, and therefore the order in which intersection shaders are executed, is unspecified.

The intersection shader of the closest AABB which intersects the ray is guaranteed to be executed at some point during traversal, unless the ray is forcibly terminated.

8.16. Any-Hit Shaders

The any-hit shader is executed after the intersection shader reports an intersection that lies within the current $[t_{\text{min}}, t_{\text{max}}]$ of the ray. The main use of any-hit shaders is to programmatically decide whether or not an intersection will be accepted. The intersection will be accepted unless the shader calls the `OpIgnoreIntersectionKHR` instruction. Any-hit shaders have read-only access to the attributes generated by the corresponding intersection shader, and can read or modify the ray payload.

8.16.1. Any-Hit Shader Execution

The order in which intersections are found along a ray, and therefore the order in which any-hit shaders are executed, is unspecified.

The any-hit shader of the closest hit is guaranteed to be executed at some point during traversal,
unless the ray is forcibly terminated.

8.17. Closest Hit Shaders

Closest hit shaders have read-only access to the attributes generated by the corresponding intersection shader, and can read or modify the ray payload. They also have access to a number of system-generated values. Closest hit shaders can call OpTraceRayKHR to recursively trace rays.

8.17.1. Closest Hit Shader Execution

Exactly one closest hit shader is executed when traversal is finished and an intersection has been found and accepted.

8.18. Miss Shaders

Miss shaders can access the ray payload and can trace new rays through the OpTraceRayKHR instruction, but cannot access attributes since they are not associated with an intersection.

8.18.1. Miss Shader Execution

A miss shader is executed instead of a closest hit shader if no intersection was found during traversal.

8.19. Callable Shaders

Callable shaders can access a callable payload that works similarly to ray payloads to do subroutine work.

8.19.1. Callable Shader Execution

A callable shader is executed by calling OpExecuteCallableKHR from an allowed shader stage.

8.20. Static Use

A SPIR-V module declares a global object in memory using the OpVariable instruction, which results in a pointer "x" to that object. A specific entry point in a SPIR-V module is said to statically use that object if that entry point's call tree contains a function containing a memory instruction or image instruction with "x" as an id operand. See the “Memory Instructions” and “Image Instructions” subsections of section 3 “Binary Form” of the SPIR-V specification for the complete list of SPIR-V memory instructions.

Static use is not used to control the behavior of variables with Input and Output storage. The effects of those variables are applied based only on whether they are present in a shader entry point's interface.
### 8.21. Scope

A scope describes a set of shader invocations, where each such set is a scope instance. Each invocation belongs to one or more scope instances, but belongs to no more than one scope instance for each scope.

The operations available between invocations in a given scope instance vary, with smaller scopes generally able to perform more operations, and with greater efficiency.

#### 8.21.1. Cross Device

All invocations executed in a Vulkan instance fall into a single cross device scope instance.

Whilst the CrossDevice scope is defined in SPIR-V, it is disallowed in Vulkan. API synchronization commands can be used to communicate between devices.

#### 8.21.2. Device

All invocations executed on a single device form a device scope instance.

If the vulkanMemoryModel and vulkanMemoryModelDeviceScope features are enabled, this scope is represented in SPIR-V by the Device Scope, which can be used as a Memory Scope for barrier and atomic operations.

If both the shaderDeviceClock and vulkanMemoryModelDeviceScope features are enabled, using the Device Scope with the OpReadClockKHR instruction will read from a clock that is consistent across invocations in the same device scope instance.

There is no method to synchronize the execution of these invocations within SPIR-V, and this can only be done with API synchronization primitives.

Invocations executing on different devices in a device group operate in separate device scope instances.

#### 8.21.3. Queue Family

Invocations executed by queues in a given queue family form a queue family scope instance.

This scope is identified in SPIR-V as the QueueFamily Scope if the vulkanMemoryModel feature is enabled, or if not, the Device Scope, which can be used as a Memory Scope for barrier and atomic operations.

If the shaderDeviceClock feature is enabled, but the vulkanMemoryModelDeviceScope feature is not enabled, using the Device Scope with the OpReadClockKHR instruction will read from a clock that is consistent across invocations in the same queue family scope instance.

There is no method to synchronize the execution of these invocations within SPIR-V, and this can only be done with API synchronization primitives.

Each invocation in a queue family scope instance must be in the same device scope instance.
8.21.4. Command

Any shader invocations executed as the result of a single command such as `vkCmdDispatch` or `vkCmdDraw` form a *command scope instance*. For indirect drawing commands with `drawCount` greater than one, invocations from separate draws are in separate command scope instances. For ray tracing shaders, an invocation group is an implementation-dependent subset of the set of shader invocations of a given shader stage which are produced by a single trace rays command.

There is no specific *Scope* for communication across invocations in a command scope instance. As this has a clear boundary at the API level, coordination here can be performed in the API, rather than in SPIR-V.

Each invocation in a command scope instance must be in the same *queue-family scope instance*.

For shaders without defined *workgroups*, this set of invocations forms an *invocation group* as defined in the SPIR-V specification.

8.21.5. Primitive

Any fragment shader invocations executed as the result of rasterization of a single primitive form a *primitive scope instance*.

There is no specific *Scope* for communication across invocations in a primitive scope instance.

Any generated *helper invocations* are included in this scope instance.

Each invocation in a primitive scope instance must be in the same *command scope instance*.

Any input variables decorated with *Flat* are uniform within a primitive scope instance.

8.21.6. Shader Call

Any *shader-call-related* invocations that are executed in one or more ray tracing execution models form a *shader call scope instance*.

The *ShaderCallKHR Scope* can be used as *Memory Scope* for barrier and atomic operations.

Each invocation in a shader call scope instance must be in the same *queue family scope instance*.

8.21.7. Workgroup

A *local workgroup* is a set of invocations that can synchronize and share data with each other using memory in the *Workgroup* storage class.

The *Workgroup Scope* can be used as both an *Execution Scope* and *Memory Scope* for barrier and atomic operations.

Each invocation in a local workgroup must be in the same *command scope instance*.

Only task, mesh, and compute shaders have defined workgroups - other shader types cannot use workgroup functionality. For shaders that have defined workgroups, this set of invocations forms
an invocation group as defined in the SPIR-V specification.

### 8.21.8. Quad

A quad scope instance is formed of four shader invocations.

In a fragment shader, each invocation in a quad scope instance is formed of invocations in neighboring framebuffer locations \((x_i, y_i)\), where:

- \(i\) is the index of the invocation within the scope instance.
- \(w\) and \(h\) are the number of pixels the fragment covers in the \(x\) and \(y\) axes.
- \(w\) and \(h\) are identical for all participating invocations.
- \((x_0) = (x_1 - w) = (x_2) = (x_3 - w)\)
- \((y_0) = (y_1) = (y_2 - h) = (y_3 - h)\)
- Each invocation has the same layer and sample indices.

In a compute shader, if the `DerivativeGroupQuadsNV` execution mode is specified, each invocation in a quad scope instance is formed of invocations with adjacent local invocation IDs \((x_i, y_i)\), where:

- \(i\) is the index of the invocation within the quad scope instance.
- \((x_0) = (x_1 - 1) = (x_2) = (x_3 - 1)\)
- \((y_0) = (y_1) = (y_2 - 1) = (y_3 - 1)\)
- \(x_0\) and \(y_0\) are integer multiples of 2.
- Each invocation has the same \(z\) coordinate.

In a compute shader, if the `DerivativeGroupLinearNV` execution mode is specified, each invocation in a quad scope instance is formed of invocations with adjacent local invocation indices \((l_i)\), where:

- \(i\) is the index of the invocation within the quad scope instance.
- \((l_0) = (l_1 - 1) = (l_2 - 2) = (l_3 - 3)\)
- \(l_0\) is an integer multiple of 4.

The specific set of invocations that make up a quad scope instance in other shader stages is undefined.

In a fragment shader, each invocation in a quad scope instance **must** be in the same primitive scope instance.

For shaders that have defined workgroups, each invocation in a quad scope instance **must** be in the same local workgroup.

In other shader stages, each invocation in a quad scope instance **must** be in the same device scope instance.

Fragment and compute shaders have defined quad scope instances.
8.21.9. Fragment Interlock

A fragment interlock scope instance is formed of fragment shader invocations based on their framebuffer locations (x,y,layer,sample), executed by commands inside a single subpass.

The specific set of invocations included varies based on the execution mode as follows:

- If the SampleInterlockOrderedEXT or SampleInterlockUnorderedEXT execution modes are used, only invocations with identical framebuffer locations (x,y,layer,sample) are included.
- If the PixelInterlockOrderedEXT or PixelInterlockUnorderedEXT execution modes are used, fragments with different sample ids are also included.
- If the ShadingRateInterlockOrderedEXT or ShadingRateInterlockUnorderedEXT execution modes are used, fragments from neighbouring framebuffer locations are also included, as determined by the shading rate.

Only fragment shaders with one of the above execution modes have defined fragment interlock scope instances.

There is no specific Scope value for communication across invocations in a fragment interlock scope instance. However, this is implicitly used as a memory scope by OpBeginInvocationInterlockEXT and OpEndInvocationInterlockEXT.

Each invocation in a fragment interlock scope instance must be in the same queue family scope instance.

8.21.10. Invocation

The smallest scope is a single invocation; this is represented by the Invocation Scope in SPIR-V.

Fragment shader invocations must be in a primitive scope instance.

Invocations in fragment shaders that have a defined fragment interlock scope must be in a fragment interlock scope instance.

Invocations in shaders that have defined workgroups must be in a local workgroup.

Invocations in shaders that have a defined quad scope must be in a quad scope instance.

All invocations in all stages must be in a command scope instance.

8.22. Derivative Operations

Derivative operations calculate the partial derivative for an expression P as a function of an invocation’s x and y coordinates.

Derivative operations operate on a set of invocations known as a derivative group as defined in the SPIR-V specification. A derivative group is equivalent to the local workgroup for a compute shader invocation, or the primitive scope instance for a fragment shader invocation.

Derivatives are calculated assuming that P is piecewise linear and continuous within the derivative
group. All dynamic instances of explicit derivative instructions (\(\text{OpDPdx}^*\), \(\text{OpDPdy}^*\), and \(\text{OpFwidth}^*\)) must be executed in control flow that is uniform within a derivative group. For other derivative operations, results are undefined if a dynamic instance is executed in control flow is not uniform within the derivative group.

Fragment shaders that statically execute derivative operations must launch sufficient invocations to ensure their correct operation; additional helper invocations are launched for framebuffer locations not covered by rasterized fragments if necessary.

Note
In a compute shader, it is the application’s responsibility to ensure that sufficient invocations are launched.

Derivative operations calculate their results as the difference between the result of \(P\) across invocations in the quad. For fine derivative operations (\(\text{OpDPdxFine}\) and \(\text{OpDPdyFine}\)), the values of \(\text{DPdx}(P)\) are calculated as

\[
\text{DPdx}(P_0) = \text{DPdx}(P_1) = P_1 - P_0
\]

\[
\text{DPdx}(P_2) = \text{DPdx}(P_3) = P_3 - P_2
\]

and the values of \(\text{DPdy}(P)\) are calculated as

\[
\text{DPdy}(P_0) = \text{DPdy}(P_2) = P_2 - P_0
\]

\[
\text{DPdy}(P_1) = \text{DPdy}(P_3) = P_3 - P_1
\]

where \(i\) is the index of each invocation as described in Quad.

Coarse derivative operations (\(\text{OpDPdxCoarse}\) and \(\text{OpDPdyCoarse}\)), calculate their results in roughly the same manner, but may only calculate two values instead of four (one for each of \(\text{DPdx}\) and \(\text{DPdy}\)), reusing the same result no matter the originating invocation. If an implementation does this, it should use the fine derivative calculations described for \(P_0\).
Note

Derivative values are calculated between fragments rather than pixels. If the fragment shader invocations involved in the calculation covers multiple pixels, these operations cover a wider area, resulting in larger derivative values. This in turn will result in a coarser level of detail being selected for image sampling operations using derivatives.

Applications may want to account for this when using multi-pixel fragments; if pixel derivatives are desired, applications should use explicit derivative operations and divide the results by the size of the fragment in each dimension as follows:

\[
\text{DPdx}(P_n)' = \frac{\text{DPdx}(P_n)}{w} \\
\text{DPdy}(P_n)' = \frac{\text{DPdy}(P_n)}{h}
\]

where \( w \) and \( h \) are the size of the fragments in the quad, and \( \text{DPdx}(P_n)' \) and \( \text{DPdy}(P_n)' \) are the pixel derivatives.

The results for \( \text{OpDPdx} \) and \( \text{OpDPdy} \) may be calculated as either fine or coarse derivatives, with implementations favouring the most efficient approach. Implementations must choose coarse or fine consistently between the two.

Executing \( \text{OpFwidthFine} \), \( \text{OpFwidthCoarse} \), or \( \text{OpFwidth} \) is equivalent to executing the corresponding \( \text{OpDPdx}^* \) and \( \text{OpDPdy}^* \) instructions, taking the absolute value of the results, and summing them.

Executing a \( \text{OpImageSampleImplicitLod} \) instruction is equivalent to executing \( \text{OpDPdx}(\text{Coordinate}) \) and \( \text{OpDPdy}(\text{Coordinate}) \), and passing the results as the \( \text{Grad} \) operands \( dx \) and \( dy \).

Note

It is expected that using the \( \text{ImplicitLod} \) variants of sampling functions will be substantially more efficient than using the \( \text{ExplicitLod} \) variants with explicitly generated derivatives.

8.23. Helper Invocations

When performing derivative operations in a fragment shader, additional invocations may be spawned in order to ensure correct results. These additional invocations are known as helper invocations and can be identified by a non-zero value in the \( \text{HelperInvocation} \) built-in. Stores and atomics performed by helper invocations must not have any effect on memory, and values returned by atomic instructions in helper invocations are undefined.

Helper invocations may become inactive at any time for any reason, with one exception. If a helper invocation would be active if it were not a helper invocation, it must be active for derivative operations.

Helper invocations may become permanently inactive if all invocations in a quad scope instance...
become helper invocations.

### 8.24. Cooperative Matrices

A *cooperative matrix* type is a SPIR-V type where the storage for and computations performed on the matrix are spread across the invocations in a scope instance. These types give the implementation freedom in how to optimize matrix multiplies.

SPIR-V defines the types and instructions, but does not specify rules about what sizes/combinations are valid, and it is expected that different implementations *may* support different sizes.

To enumerate the supported cooperative matrix types and operations, call:

```c
VkResult vkGetPhysicalDeviceCooperativeMatrixPropertiesNV(
    VkPhysicalDevice                            physicalDevice,
    uint32_t*                                   pPropertyCount,
    VkCooperativeMatrixPropertiesNV*            pProperties);
```

- `physicalDevice` is the physical device.
- `pPropertyCount` is a pointer to an integer related to the number of cooperative matrix properties available or queried.
- `pProperties` is either `NULL` or a pointer to an array of `VkCooperativeMatrixPropertiesNV` structures.

If `pProperties` is `NULL`, then the number of cooperative matrix properties available is returned in `pPropertyCount`. Otherwise, `pPropertyCount` must point to a variable set by the user to the number of elements in the `pProperties` array, and on return the variable is overwritten with the number of structures actually written to `pProperties`. If `pPropertyCount` is less than the number of cooperative matrix properties available, at most `pPropertyCount` structures will be written. If `pPropertyCount` is smaller than the number of cooperative matrix properties available, `VK_INCOMPLETE` will be returned instead of `VK_SUCCESS`, to indicate that not all the available cooperative matrix properties were returned.

### Valid Usage (Implicit)

- `physicalDevice` must be a valid `VkPhysicalDevice` handle
- `pPropertyCount` must be a valid pointer to a `uint32_t` value
- If the value referenced by `pPropertyCount` is not 0, and `pProperties` is not `NULL`, `pProperties` must be a valid pointer to an array of `pPropertyCount` `VkCooperativeMatrixPropertiesNV` structures
**Return Codes**

**Success**
- `VK_SUCCESS`
- `VK_INCOMPLETE`

**Failure**
- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

Each `VkCooperativeMatrixPropertiesNV` structure describes a single supported combination of types for a matrix multiply/add operation (`OpCooperativeMatrixMulAddNV`). The multiply can be described in terms of the following variables and types (in SPIR-V pseudocode):

\[
\begin{align*}
\%A &= \text{of type OpTypeCooperativeMatrixNV} \quad \%AType \quad \%scope \quad \%MSize \quad \%KSize \\
\%B &= \text{of type OpTypeCooperativeMatrixNV} \quad \%BType \quad \%scope \quad \%KSize \quad \%NSize \\
\%C &= \text{of type OpTypeCooperativeMatrixNV} \quad \% CType \quad \%scope \quad \%MSize \quad \%NSize \\
\%D &= \text{of type OpTypeCooperativeMatrixNV} \quad \% Dtype \quad \%scope \quad \%MSize \quad \%NSize \\
\%D &= \%A \times \%B + \%C \\
\end{align*}
\]

A matrix multiply with these dimensions is known as an \(MxNxK\) matrix multiply.

The `VkCooperativeMatrixPropertiesNV` structure is defined as:

```c
typedef struct VkCooperativeMatrixPropertiesNV {
    VkStructureType      sType;
    void*                pNext;
    uint32_t             MSize;
    uint32_t             NSize;
    uint32_t             KSize;
    VkComponentTypeNV    AType;
    VkComponentTypeNV    BType;
    VkComponentTypeNV    CType;
    VkComponentTypeNV    Dtype;
    VkScopeNV            scope;
} VkCooperativeMatrixPropertiesNV;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `MSize` is the number of rows in matrices A, C, and D.
- `KSize` is the number of columns in matrix A and rows in matrix B.
- `NSize` is the number of columns in matrices B, C, D.
• AType is the component type of matrix A, of type VkComponentTypeNV.
• BType is the component type of matrix B, of type VkComponentTypeNV.
• CType is the component type of matrix C, of type VkComponentTypeNV.
• DType is the component type of matrix D, of type VkComponentTypeNV.
• scope is the scope of all the matrix types, of type VkScopeNV.

If some types are preferred over other types (e.g. for performance), they should appear earlier in the list enumerated by vkGetPhysicalDeviceCooperativeMatrixPropertiesNV.

At least one entry in the list must have power of two values for all of MSize, KSize, and NSize.

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_COOPERATIVE_MATRIX_PROPERTIES_NV
• pNext must be NULL
• AType must be a valid VkComponentTypeNV value
• BType must be a valid VkComponentTypeNV value
• CType must be a valid VkComponentTypeNV value
• DType must be a valid VkComponentTypeNV value
• scope must be a valid VkScopeNV value

Possible values for VkScopeNV include:

typedef enum VkScopeNV {
    VK_SCOPE_DEVICE_NV = 1,
    VK_SCOPE_WORKGROUP_NV = 2,
    VK_SCOPE_SUBGROUP_NV = 3,
    VK_SCOPE_QUEUE_FAMILY_NV = 5,
} VkScopeNV;

• VK_SCOPE_DEVICE_NV corresponds to SPIR-V Device scope.
• VK_SCOPE_WORKGROUP_NV corresponds to SPIR-V Workgroup scope.
• VK_SCOPE_SUBGROUP_NV corresponds to SPIR-V Subgroup scope.
• VK_SCOPE_QUEUE_FAMILY_NV corresponds to SPIR-V QueueFamily scope.

All enum values match the corresponding SPIR-V value.

Possible values for VkComponentTypeNV include:
typedef enum VkComponentTypeNV {
    VK_COMPONENT_TYPE_FLOAT16_NV = 0,
    VK_COMPONENT_TYPE_FLOAT32_NV = 1,
    VK_COMPONENT_TYPE_FLOAT64_NV = 2,
    VK_COMPONENT_TYPE_SINT8_NV = 3,
    VK_COMPONENT_TYPE_SINT16_NV = 4,
    VK_COMPONENT_TYPE_SINT32_NV = 5,
    VK_COMPONENT_TYPE_SINT64_NV = 6,
    VK_COMPONENT_TYPE_UINT8_NV = 7,
    VK_COMPONENT_TYPE_UINT16_NV = 8,
    VK_COMPONENT_TYPE_UINT32_NV = 9,
    VK_COMPONENT_TYPE_UINT64_NV = 10,
} VkComponentTypeNV;

• VK_COMPONENT_TYPE_FLOAT16_NV corresponds to SPIR-V OpTypeFloat 16.
• VK_COMPONENT_TYPE_FLOAT32_NV corresponds to SPIR-V OpTypeFloat 32.
• VK_COMPONENT_TYPE_FLOAT64_NV corresponds to SPIR-V OpTypeFloat 64.
• VK_COMPONENT_TYPE_SINT8_NV corresponds to SPIR-V OpTypeInt 8 1.
• VK_COMPONENT_TYPE_SINT16_NV corresponds to SPIR-V OpTypeInt 16 1.
• VK_COMPONENT_TYPE_SINT32_NV corresponds to SPIR-V OpTypeInt 32 1.
• VK_COMPONENT_TYPE_SINT64_NV corresponds to SPIR-V OpTypeInt 64 1.
• VK_COMPONENT_TYPE_UINT8_NV corresponds to SPIR-V OpTypeInt 8 0.
• VK_COMPONENT_TYPE_UINT16_NV corresponds to SPIR-V OpTypeInt 16 0.
• VK_COMPONENT_TYPE_UINT32_NV corresponds to SPIR-V OpTypeInt 32 0.
• VK_COMPONENT_TYPE_UINT64_NV corresponds to SPIR-V OpTypeInt 64 0.

8.25. Validation Cache

Validation cache objects allow the result of internal validation to be reused, both within a single application run and between multiple runs. Reuse within a single run is achieved by passing the same validation cache object when creating supported Vulkan objects. Reuse across runs of an application is achieved by retrieving validation cache contents in one run of an application, saving the contents, and using them to preinitialize a validation cache on a subsequent run. The contents of the validation cache objects are managed by the validation layers. Applications can manage the host memory consumed by a validation cache object and control the amount of data retrieved from a validation cache object.

Validation cache objects are represented by VkValidationCacheEXT handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkValidationCacheEXT)
```

To create validation cache objects, call:
VkResult vkCreateValidationCacheEXT(
    VkDevice                                    device,
    constVkValidationCacheCreateInfoEXT*       pCreateInfo,
    constVkAllocationCallbacks*                pAllocator,
    VkValidationCacheEXT*                       pValidationCache);

• **device** is the logical device that creates the validation cache object.

• **pCreateInfo** is a pointer to a VkValidationCacheCreateInfoEXT structure containing the initial parameters for the validation cache object.

• **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.

• **pValidationCache** is a pointer to a VkValidationCacheEXT handle in which the resulting validation cache object is returned.

**Note**

Applications can track and manage the total host memory size of a validation cache object using the **pAllocator**. Applications can limit the amount of data retrieved from a validation cache object in vkGetValidationCacheDataEXT. Implementations should not internally limit the total number of entries added to a validation cache object or the total host memory consumed.

Once created, a validation cache can be passed to the vkCreateShaderModule command by adding this object to the VkShaderModuleCreateInfo structure’s **pNext** chain. If a VkShaderModuleValidationCacheCreateInfoEXT object is included in the VkShaderModuleCreateInfo::pNext chain, and its validationCache field is not VK_NULL_HANDLE, the implementation will query it for possible reuse opportunities and update it with new content. The use of the validation cache object in these commands is internally synchronized, and the same validation cache object can be used in multiple threads simultaneously.

**Note**

Implementations should make every effort to limit any critical sections to the actual accesses to the cache, which is expected to be significantly shorter than the duration of the vkCreateShaderModule command.

**Valid Usage (Implicit)**

- **device** must be a valid VkDevice handle

- **pCreateInfo** must be a valid pointer to a valid VkValidationCacheCreateInfoEXT structure

- If **pAllocator** is not **NULL**, **pAllocator** must be a valid pointer to a valid VkAllocationCallbacks structure

- **pValidationCache** must be a valid pointer to a VkValidationCacheEXT handle
Return Codes

Success
  • VK_SUCCESS

Failure
  • VK_ERROR_OUT_OF_HOST_MEMORY

The `VkValidationCacheCreateInfoEXT` structure is defined as:

```c
typedef struct VkValidationCacheCreateInfoEXT {
    VkStructureType                    sType;
    const void*                        pNext;
    VkValidationCacheCreateFlagsEXT    flags;
    size_t                             initialDataSize;
    const void*                        pInitialData;
} VkValidationCacheCreateInfoEXT;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `flags` is reserved for future use.
- `initialDataSize` is the number of bytes in `pInitialData`. If `initialDataSize` is zero, the validation cache will initially be empty.
- `pInitialData` is a pointer to previously retrieved validation cache data. If the validation cache data is incompatible (as defined below) with the device, the validation cache will be initially empty. If `initialDataSize` is zero, `pInitialData` is ignored.

Valid Usage

- If `initialDataSize` is not 0, it **must** be equal to the size of `pInitialData`, as returned by `vkGetValidationCacheDataEXT` when `pInitialData` was originally retrieved
- If `initialDataSize` is not 0, `pInitialData` **must** have been retrieved from a previous call to `vkGetValidationCacheDataEXT`

Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_VALIDATION_CACHE_CREATE_INFO_EXT`
- `pNext` **must** be `NULL`
- `flags` **must** be 0
- If `initialDataSize` is not 0, `pInitialData` **must** be a valid pointer to an array of `initialDataSize` bytes
**typedef** VkFlags VkValidationCacheCreateFlagsEXT;

`VkValidationCacheCreateFlagsEXT` is a bitmask type for setting a mask, but is currently reserved for future use.

Validation cache objects **can** be merged using the command:

```c
VkResult vkMergeValidationCachesEXT(
    VkDevice                                    device,
    VkValidationCacheEXT                        dstCache,
    uint32_t                                    srcCacheCount,
    const VkValidationCacheEXT*                 pSrcCaches);
```

- **device** is the logical device that owns the validation cache objects.
- **dstCache** is the handle of the validation cache to merge results into.
- **srcCacheCount** is the length of the `pSrcCaches` array.
- **pSrcCaches** is a pointer to an array of validation cache handles, which will be merged into `dstCache`. The previous contents of `dstCache` are included after the merge.

**Note**

The details of the merge operation are implementation dependent, but implementations **should** merge the contents of the specified validation caches and prune duplicate entries.

**Valid Usage**

- **dstCache** must not appear in the list of source caches

**Valid Usage (Implicit)**

- **device** must be a valid `VkDevice` handle
- **dstCache** must be a valid `VkValidationCacheEXT` handle
- **pSrcCaches** must be a valid pointer to an array of `srcCacheCount` valid `VkValidationCacheEXT` handles
- **srcCacheCount** must be greater than 0
- **dstCache** must have been created, allocated, or retrieved from `device`
- Each element of **pSrcCaches** must have been created, allocated, or retrieved from `device`
Host Synchronization

- Host access to `dstCache` must be externally synchronized.

Return Codes

**Success**
- `VK_SUCCESS`

**Failure**
- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

Data can be retrieved from a validation cache object using the command:

```c
VkResult vkGetValidationCacheDataEXT(
    VkDevice                                    device,  // device is the logical device that owns the validation cache.
    VkValidationCacheEXT                        validationCache, // validationCache is the validation cache to retrieve data from.
    size_t*                                     pDataSize,  // pDataSize is a pointer to a value related to the amount of data in the validation cache, as described below.
    void*                                       pData); // pData is either NULL or a pointer to a buffer.
```

If `pData` is `NULL`, then the maximum size of the data that can be retrieved from the validation cache, in bytes, is returned in `pDataSize`. Otherwise, `pDataSize` must point to a variable set by the user to the size of the buffer, in bytes, pointed to by `pData`, and on return the variable is overwritten with the amount of data actually written to `pData`.

If `pDataSize` is less than the maximum size that can be retrieved by the validation cache, at most `pDataSize` bytes will be written to `pData`, and `vkGetValidationCacheDataEXT` will return `VK_INCOMPLETE`. Any data written to `pData` is valid and can be provided as the `pInitialData` member of the `VkValidationCacheCreateInfoEXT` structure passed to `vkCreateValidationCacheEXT`.

Two calls to `vkGetValidationCacheDataEXT` with the same parameters must retrieve the same data unless a command that modifies the contents of the cache is called between them.

Applications can store the data retrieved from the validation cache, and use these data, possibly in a future run of the application, to populate new validation cache objects. The results of validation, however, may depend on the vendor ID, device ID, driver version, and other details of the device. To enable applications to detect when previously retrieved data is incompatible with the device, the...
initial bytes written to pData must be a header consisting of the following members:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Size</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>length in bytes of the entire validation cache header written as a stream of bytes, with the least significant byte first</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>a VkValidationCacheHeaderVersionEXT value written as a stream of bytes, with the least significant byte first</td>
</tr>
<tr>
<td>8</td>
<td>VK_UUID_SIZE</td>
<td>a layer commit ID expressed as a UUID, which uniquely identifies the version of the validation layers used to generate these validation results</td>
</tr>
</tbody>
</table>

The first four bytes encode the length of the entire validation cache header, in bytes. This value includes all fields in the header including the validation cache version field and the size of the length field.

The next four bytes encode the validation cache version, as described for VkValidationCacheHeaderVersionEXT. A consumer of the validation cache should use the cache version to interpret the remainder of the cache header.

If pDataSize is less than what is necessary to store this header, nothing will be written to pData and zero will be written to pDataSize.

Valid Usage (Implicit)

- device must be a valid VkDevice handle
- validationCache must be a valid VkValidationCacheEXT handle
- pDataSize must be a valid pointer to a size_t value
- If the value referenced by pDataSize is not 0, and pData is not NULL, pData must be a valid pointer to an array of pDataSize bytes
- validationCache must have been created, allocated, or retrieved from device
Return Codes

Success

• VK_SUCCESS
• VK_INCOMPLETE

Failure

• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

Possible values of the second group of four bytes in the header returned by vkGetValidationCacheDataEXT, encoding the validation cache version, are:

```
typedef enum VkValidationCacheHeaderVersionEXT {
    VK_VALIDATION_CACHE_HEADER_VERSION_ONE_EXT = 1,
} VkValidationCacheHeaderVersionEXT;
```

• VK_VALIDATION_CACHE_HEADER_VERSION_ONE_EXT specifies version one of the validation cache.

To destroy a validation cache, call:

```
void vkDestroyValidationCacheEXT(
    VkDevice device,
    VkValidationCacheEXT validationCache,
    const VkAllocationCallbacks* pAllocator);
```

• device is the logical device that destroys the validation cache object.
• validationCache is the handle of the validation cache to destroy.
• pAllocator controls host memory allocation as described in the Memory Allocation chapter.

Valid Usage

• If VkAllocationCallbacks were provided when validationCache was created, a compatible set of callbacks must be provided here
• If no VkAllocationCallbacks were provided when validationCache was created, pAllocator must be NULL
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle

- If `validationCache` is not `VK_NULL_HANDLE`, `validationCache` must be a valid `VkValidationCacheEXT` handle

- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure

- If `validationCache` is a valid handle, it must have been created, allocated, or retrieved from `device`

Host Synchronization

- Host access to `validationCache` must be externally synchronized
Chapter 9. Pipelines

The following figure shows a block diagram of the Vulkan pipelines. Some Vulkan commands specify geometric objects to be drawn or computational work to be performed, while others specify state controlling how objects are handled by the various pipeline stages, or control data transfer between memory organized as images and buffers. Commands are effectively sent through a processing pipeline, either a graphics pipeline, a ray tracing pipeline, or a compute pipeline.

The graphics pipeline can be operated in two modes, as either primitive shading or mesh shading pipeline.

Primitive Shading

The first stage of the graphics pipeline (Input Assembler) assembles vertices to form geometric primitives such as points, lines, and triangles, based on a requested primitive topology. In the next stage (Vertex Shader) vertices can be transformed, computing positions and attributes for each vertex. If tessellation and/or geometry shaders are supported, they can then generate multiple primitives from a single input primitive, possibly changing the primitive topology or generating additional attribute data in the process.

Mesh Shading

When using the mesh shading pipeline input primitives are not assembled implicitly, but explicitly through the (Mesh Shader). The work on the mesh pipeline is initiated by the application drawing a set of mesh tasks.

If an optional (Task Shader) is active, each task triggers the execution of a task shader workgroup that will generate a new set of tasks upon completion. Each of these spawned tasks, or each of the original dispatched tasks if no task shader is present, triggers the execution of a mesh shader workgroup that produces an output mesh with a variable-sized number of primitives assembled from vertices stored in the output mesh.

Common

The final resulting primitives are clipped to a clip volume in preparation for the next stage, Rasterization. The rasterizer produces a series of fragments associated with a region of the framebuffer, from a two-dimensional description of a point, line segment, or triangle. These fragments are processed by fragment operations to determine whether generated values will be written to the framebuffer. fragment shading determines the values to be written to the framebuffer attachments. Framebuffer operations then read and write the color and depth/stencil attachments of the framebuffer for a given subpass of a render pass instance. The attachments can be used as input attachments in the fragment shader in a later subpass of the same render pass.

The compute pipeline is a separate pipeline from the graphics pipeline, which operates on one-, two-, or three-dimensional workgroups which can read from and write to buffer and image memory.

This ordering is meant only as a tool for describing Vulkan, not as a strict rule of how Vulkan is implemented, and we present it only as a means to organize the various operations of the pipelines.
Actual ordering guarantees between pipeline stages are explained in detail in the synchronization chapter.

![Block diagram of the Vulkan pipeline](image)

**Figure 2. Block diagram of the Vulkan pipeline**

Each pipeline is controlled by a monolithic object created from a description of all of the shader stages and any relevant fixed-function stages. Linking the whole pipeline together allows the optimization of shaders based on their input/outputs and eliminates expensive draw time state validation.

A pipeline object is bound to the current state using `vkCmdBindPipeline`. Any pipeline object state that is specified as *dynamic* is not applied to the current state when the pipeline object is bound, but is instead set by dynamic state setting commands.

No state, including dynamic state, is inherited from one command buffer to another.

Compute, ray tracing, and graphics pipelines are each represented by `VkPipeline` handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkPipeline)
```

## 9.1. Compute Pipelines

Compute pipelines consist of a single static compute shader stage and the pipeline layout.

The compute pipeline represents a compute shader and is created by calling `vkCreateComputePipelines` with `module` and `pName` selecting an entry point from a shader module, where that entry point defines a valid compute shader, in the `VkPipelineShaderStageCreateInfo` structure contained within the `VkComputePipelineCreateInfo` structure.

To create compute pipelines, call:
VkResult vkCreateComputePipelines(
    VkDevice                                    device,
    VkPipelineCache                             pipelineCache,
    uint32_t                                    createInfoCount,
    const VkComputePipelineCreateInfo*          pCreateInfos,
    const VkAllocationCallbacks*                pAllocator,
    VkPipeline*                                 pPipelines);

- **device** is the logical device that creates the compute pipelines.
- **pipelineCache** is either **VK_NULL_HANDLE**, indicating that pipeline caching is disabled; or the handle of a valid pipeline cache object, in which case use of that cache is enabled for the duration of the command.
- **createInfoCount** is the length of the pCreateInfos and pPipelines arrays.
- **pCreateInfos** is a pointer to an array of VkComputePipelineCreateInfo structures.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pPipelines** is a pointer to an array of VkPipeline handles in which the resulting compute pipeline objects are returned.

## Valid Usage

- If the **flags** member of any element of pCreateInfos contains the **VK_PIPELINE_CREATE_DERIVATIVE_BIT** flag, and the basePipelineIndex member of that same element is not -1, basePipelineIndex must be less than the index into pCreateInfos that corresponds to that element.
- If the **flags** member of any element of pCreateInfos contains the **VK_PIPELINE_CREATE_DERIVATIVE_BIT** flag, the base pipeline must have been created with the **VK_PIPELINE_CREATE_ALLOW_DERIVATIVES_BIT** flag set.
- If pipelineCache was created with **VK_PIPELINE_CACHE_CREATE_EXTERNALLY_SYNCHRONIZED_BIT_EXT**, host access to pipelineCache must be externally synchronized.
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- If `pipelineCache` is not `VK_NULL_HANDLE`, `pipelineCache` must be a valid `VkPipelineCache` handle
- `pCreateInfos` must be a valid pointer to an array of `createInfoCount` valid `VkComputePipelineCreateInfo` structures
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- `pPipelines` must be a valid pointer to an array of `createInfoCount` `VkPipeline` handles
- `createInfoCount` must be greater than 0
- If `pipelineCache` is a valid handle, it must have been created, allocated, or retrieved from `device`

Return Codes

**Success**
- `VK_SUCCESS`
- `VK_PIPELINE_COMPILE_REQUIRED_EXT`

**Failure**
- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`
- `VK_ERROR_INVALID_SHADER_NV`

The `VkComputePipelineCreateInfo` structure is defined as:

```c
typedef struct VkComputePipelineCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkPipelineCreateFlags flags;
    VkPipelineShaderStageCreateInfo stage;
    VkPipelineLayout layout;
    VkPipeline basePipelineHandle;
    int32_t basePipelineIndex;
} VkComputePipelineCreateInfo;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `flags` is a bitmask of `VkPipelineCreateFlagBits` specifying how the pipeline will be generated.
- `stage` is a `VkPipelineShaderStageCreateInfo` structure describing the compute shader.
• **layout** is the description of binding locations used by both the pipeline and descriptor sets used with the pipeline.

• **basePipelineHandle** is a pipeline to derive from

• **basePipelineIndex** is an index into the **pCreateInfos** parameter to use as a pipeline to derive from

The parameters **basePipelineHandle** and **basePipelineIndex** are described in more detail in [Pipeline Derivatives](#).

### Valid Usage

<table>
<thead>
<tr>
<th>Condition</th>
<th>Requirement</th>

<td></td>
</tr>
</tbody>
</table>
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_COMPUTE_PIPELINE_CREATE_INFO`.
- Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkPipelineCompilerControlCreateInfoAMD` or `VkPipelineCreationFeedbackCreateInfoEXT`.
- The `sType` value of each struct in the `pNext` chain must be unique.
- `flags` must be a valid combination of `VkPipelineCreateFlagBits` values.
- `stage` must be a valid `VkPipelineShaderStageCreateInfo` structure.
- `layout` must be a valid `VkPipelineLayout` handle.
- Both of `basePipelineHandle`, and `layout` that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`.

The `VkPipelineShaderStageCreateInfo` structure is defined as:

```c
typedef struct VkPipelineShaderStageCreateInfo {
    VkStructureType                     sType;
    const void*                         pNext;
    VkPipelineShaderStageCreateFlags    flags;
    VkShaderStageFlagBits               stage;
    VkShaderModule                      module;
    const char*                         pName;
    const VkSpecializationInfo*         pSpecializationInfo;
} VkPipelineShaderStageCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkPipelineShaderStageCreateFlagBits` specifying how the pipeline shader stage will be generated.
- **stage** is a `VkShaderStageFlagBits` value specifying a single pipeline stage.
- **module** is a `VkShaderModule` object containing the shader for this stage.
- **pName** is a pointer to a null-terminated UTF-8 string specifying the entry point name of the shader for this stage.
- **pSpecializationInfo** is a pointer to a `VkSpecializationInfo` structure, as described in `Specialization Constants`, or `NULL`.

374 | Chapter 9. Pipelines
Valid Usage

- If the `geometry shaders` feature is not enabled, `stage` must not be `VK_SHADER_STAGE_GEOMETRY_BIT`.
- If the `tessellation shaders` feature is not enabled, `stage` must not be `VK_SHADER_STAGE_TESSELLATION_CONTROL_BIT` or `VK_SHADER_STAGE_TESSELLATION_EVALUATION_BIT`.
- If the `mesh shader` feature is not enabled, `stage` must not be `VK_SHADER_STAGE_MESH_BIT_NV`.
- If the `task shader` feature is not enabled, `stage` must not be `VK_SHADER_STAGE_TASK_BIT_NV`.
- `stage` must not be `VK_SHADER_STAGE_ALL_GRAPHICS`, or `VK_SHADER_STAGE_ALL`.
- `pName` must be the name of an `OpEntryPoint` in `module` with an execution model that matches `stage`.
- If the identified entry point includes any variable in its interface that is declared with the `ClipDistance BuiltIn` decoration, that variable must not have an array size greater than `VkPhysicalDeviceLimits::maxClipDistances`.
- If the identified entry point includes any variable in its interface that is declared with the `CullDistance BuiltIn` decoration, that variable must not have an array size greater than `VkPhysicalDeviceLimits::maxCullDistances`.
- If the identified entry point includes any variables in its interface that are declared with the `ClipDistance` or `CullDistance BuiltIn` decoration, those variables must not have array sizes which sum to more than `VkPhysicalDeviceLimits::maxCombinedClipAndCullDistances`.
- If the identified entry point includes any variable in its interface that is declared with the `SampleMask BuiltIn` decoration, that variable must not have an array size greater than `VkPhysicalDeviceLimits::maxSampleMaskWords`.
- If `stage` is `VK_SHADER_STAGE_VERTEX_BIT`, the identified entry point must not include any input variable in its interface that is decorated with `CullDistance`.
- If `stage` is `VK_SHADER_STAGE_TESSELLATION_CONTROL_BIT` or `VK_SHADER_STAGE_TESSELLATION_EVALUATION_BIT`, and the identified entry point has an `OpExecutionMode` instruction that specifies a patch size with `OutputVertices`, the patch size must be greater than 0 and less than or equal to `VkPhysicalDeviceLimits::maxTessellationPatchSize`.
- If `stage` is `VK_SHADER_STAGE_GEOMETRY_BIT`, the identified entry point must have an `OpExecutionMode` instruction that specifies a maximum output vertex count that is greater than 0 and less than or equal to `VkPhysicalDeviceLimits::maxGeometryOutputVertices`.
- If `stage` is `VK_SHADER_STAGE_GEOMETRY_BIT`, the identified entry point must have an `OpExecutionMode` instruction that specifies an invocation count that is greater than 0 and less than or equal to `VkPhysicalDeviceLimits::maxGeometryShaderInvocations`.
- If `stage` is a vertex processing stage, and the identified entry point writes to `Layer` for any primitive, it must write the same value to `Layer` for all vertices of a given primitive.
- If `stage` is a vertex processing stage, and the identified entry point writes to `ViewportIndex` for any primitive, it must write the same value to `ViewportIndex` for all vertices of a given primitive.
• If `stage` is `VK_SHADER_STAGE_FRAGMENT_BIT`, the identified entry point **must** not include any output variables in its interface decorated with `CullDistance`.

• If `stage` is `VK_SHADER_STAGE_FRAGMENT_BIT`, and the identified entry point writes to `FragDepth` in any execution path, it **must** write to `FragDepth` in all execution paths.

• If `stage` is `VK_SHADER_STAGE_FRAGMENT_BIT`, and the identified entry point writes to `FragStencilRefEXT` in any execution path, it **must** write to `FragStencilRefEXT` in all execution paths.

• If `stage` is `VK_SHADER_STAGE_MESH_BIT_NV`, the identified entry point **must** have an `OpExecutionMode` instruction that specifies a maximum output vertex count, `OutputVertices`, that is greater than 0 and less than or equal to `VkPhysicalDeviceMeshShaderPropertiesNV::maxMeshOutputVertices`.

• If `stage` is `VK_SHADER_STAGE_MESH_BIT_NV`, the identified entry point **must** have an `OpExecutionMode` instruction that specifies a maximum output primitive count, `OutputPrimitivesNV`, that is greater than 0 and less than or equal to `VkPhysicalDeviceMeshShaderPropertiesNV::maxMeshOutputPrimitives`.

• If `flags` has the `VK_PIPELINE_SHADER_STAGE_CREATE_ALLOW_VARYING_SUBGROUP_SIZE_BIT_EXT` flag set, the `subgroupSizeControl` feature **must** be enabled.

• If `flags` has the `VK_PIPELINE_SHADER_STAGE_CREATE_REQUIRE_FULL_SUBGROUPS_BIT_EXT` flag set, the `computeFullSubgroups` feature **must** be enabled.

• If a `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT` structure is included in the `pNext` chain, `flags` **must** not have the `VK_PIPELINE_SHADER_STAGE_CREATE_ALLOW_VARYING_SUBGROUP_SIZE_BIT_EXT` flag set.

• If a `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT` structure is included in the `pNext` chain, the `subgroupSizeControl` feature **must** be enabled, and `stage` **must** be a valid bit specified in `requiredSubgroupSizeStages`.

• If a `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT` structure is included in the `pNext` chain and `stage` is `VK_SHADER_STAGE_COMPUTE_BIT`, the local workgroup size of the shader **must** be less than or equal to the product of `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT::requiredSubgroupSize` and `maxComputeWorkgroupSubgroups`.

• If a `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT` structure is included in the `pNext` chain, and `flags` has the `VK_PIPELINE_SHADER_STAGE_CREATE_REQUIRE_FULL_SUBGROUPS_BIT_EXT` flag set, the local workgroup size in the X dimension of the pipeline **must** be a multiple of `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT::requiredSubgroupSize`.

• If `flags` has both the `VK_PIPELINE_SHADER_STAGE_CREATE_REQUIRE_FULL_SUBGROUPS_BIT_EXT` and `VK_PIPELINE_SHADER_STAGE_CREATE_ALLOW_VARYING_SUBGROUP_SIZE_BIT_EXT` flags set, the local workgroup size in the X dimension of the pipeline **must** be a multiple of `maxSubgroupSize`.

• If `flags` has the `VK_PIPELINE_SHADER_STAGE_CREATE_REQUIRE_FULL_SUBGROUPS_BIT_EXT` flag set and `flags` **does not** have the `VK_PIPELINE_SHADER_STAGE_CREATE_ALLOW_VARYING_SUBGROUP_SIZE_BIT_EXT` flag set and no `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT` structure is included in the `pNext` chain, the local workgroup size in the X dimension of the pipeline **must** be a...
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_PIPELINE_SHADER_STAGE_CREATE_INFO`
- **pNext** must be `NULL` or a pointer to a valid instance of `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT`
- The **sType** value of each struct in the **pNext** chain must be unique
- **flags** must be a valid combination of `VkPipelineShaderStageCreateFlagBits` values
- **stage** must be a valid `VkShaderStageFlagBits` value
- **module** must be a valid `VkShaderModule` handle
- **pName** must be a null-terminated UTF-8 string
- If **pSpecializationInfo** is not `NULL`, **pSpecializationInfo** must be a valid pointer to a valid `VkSpecializationInfo` structure

```plaintext
typedef VkFlags VkPipelineShaderStageCreateFlags;
```

`VkPipelineShaderStageCreateFlags` is a bitmask type for setting a mask of zero or more `VkPipelineShaderStageCreateFlagBits`.

Possible values of the **flags** member of `VkPipelineShaderStageCreateInfo` specifying how a pipeline shader stage is created, are:

```plaintext
typedef enum VkPipelineShaderStageCreateFlagBits {
    VK_PIPELINE_SHADER_STAGE_CREATE_ALLOW_VARYING_SUBGROUP_SIZE_BIT_EXT = 0x00000001,
    VK_PIPELINE_SHADER_STAGE_CREATE_REQUIRE_FULL_SUBGROUPS_BIT_EXT = 0x00000002,
} VkPipelineShaderStageCreateFlagBits;
```

- **VK_PIPELINE_SHADER_STAGE_CREATE_ALLOW_VARYING_SUBGROUP_SIZE_BIT_EXT** specifies that the SubgroupSize may vary in the shader stage.
- **VK_PIPELINE_SHADER_STAGE_CREATE_REQUIRE_FULL_SUBGROUPS_BIT_EXT** specifies that the subgroup sizes must be launched with all invocations active in the compute stage.

**Note**

If **VK_PIPELINE_SHADER_STAGE_CREATE_ALLOW_VARYING_SUBGROUP_SIZE_BIT_EXT** and **VK_PIPELINE_SHADER_STAGE_CREATE_REQUIRE_FULL_SUBGROUPS_BIT_EXT** are specified and `minSubgroupSize` does not equal `maxSubgroupSize` and no required subgroup size is specified, then the only way to guarantee that the 'X' dimension of the local workgroup size is a multiple of **SubgroupSize** is to make it a multiple of **maxSubgroupSize**. Under these conditions, you are guaranteed full subgroups but not any particular subgroup size.
Commands and structures which need to specify one or more shader stages do so using a bitmask whose bits correspond to stages. Bits which can be set to specify shader stages are:

```c
typedef enum VkShaderStageFlagBits {
    VK_SHADER_STAGE_VERTEX_BIT = 0x00000001,
    VK_SHADER_STAGE_TESSELLATION_CONTROL_BIT = 0x00000002,
    VK_SHADER_STAGE_TESSELLATION_EVALUATION_BIT = 0x00000004,
    VK_SHADER_STAGE_GEOMETRY_BIT = 0x00000008,
    VK_SHADER_STAGE_FRAGMENT_BIT = 0x00000010,
    VK_SHADER_STAGE_COMPUTE_BIT = 0x00000020,
    VK_SHADER_STAGE_ALL_GRAPHICS = 0x0000001F,
    VK_SHADER_STAGE_ALL = 0x7FFFFFFF,
    VK_SHADER_STAGE_RAYGEN_BIT_KHR = 0x00000100,
    VK_SHADER_STAGE_ANY_HIT_BIT_KHR = 0x00000200,
    VK_SHADER_STAGE_CLOSEST_HIT_BIT_KHR = 0x00000400,
    VK_SHADER_STAGE_MISS_BIT_KHR = 0x00000800,
    VK_SHADER_STAGE_INTERSECTION_BIT_KHR = 0x00001000,
    VK_SHADER_STAGE_CALLABLE_BIT_KHR = 0x00002000,
    VK_SHADER_STAGE_TASK_BIT_NV = 0x00000040,
    VK_SHADER_STAGE_MESH_BIT_NV = 0x00000080,
    VK_SHADER_STAGE_RAYGEN_BIT_NV = VK_SHADER_STAGE_RAYGEN_BIT_KHR,
    VK_SHADER_STAGE_ANY_HIT_BIT_NV = VK_SHADER_STAGE_ANY_HIT_BIT_KHR,
    VK_SHADER_STAGE_CLOSEST_HIT_BIT_NV = VK_SHADER_STAGE_CLOSEST_HIT_BIT_KHR,
    VK_SHADER_STAGE_MISS_BIT_NV = VK_SHADER_STAGE_MISS_BIT_KHR,
    VK_SHADER_STAGE_INTERSECTION_BIT_NV = VK_SHADER_STAGE_INTERSECTION_BIT_KHR,
    VK_SHADER_STAGE_CALLABLE_BIT_NV = VK_SHADER_STAGE_CALLABLE_BIT_KHR,
} VkShaderStageFlagBits;
```

- **VK_SHADER_STAGE_VERTEX_BIT** specifies the vertex stage.
- **VK_SHADER_STAGE_TESSELLATION_CONTROL_BIT** specifies the tessellation control stage.
- **VK_SHADER_STAGE_TESSELLATION_EVALUATION_BIT** specifies the tessellation evaluation stage.
- **VK_SHADER_STAGE_GEOMETRY_BIT** specifies the geometry stage.
- **VK_SHADER_STAGE_FRAGMENT_BIT** specifies the fragment stage.
- **VK_SHADER_STAGE_COMPUTE_BIT** specifies the compute stage.
- **VK_SHADER_STAGE_ALL_GRAPHICS** is a combination of bits used as shorthand to specify all graphics stages defined above (excluding the compute stage).
- **VK_SHADER_STAGE_ALL** is a combination of bits used as shorthand to specify all shader stages supported by the device, including all additional stages which are introduced by extensions.
- **VK_SHADER_STAGE_TASK_BIT_NV** specifies the task stage.
- **VK_SHADER_STAGE_MESH_BIT_NV** specifies the mesh stage.
- **VK_SHADER_STAGE_RAYGEN_BIT_KHR** specifies the ray generation stage.
- **VK_SHADER_STAGE_ANY_HIT_BIT_KHR** specifies the any-hit stage.
- **VK_SHADER_STAGE_CLOSEST_HIT_BIT_KHR** specifies the closest hit stage.
• **VK_SHADER_STAGE_MISS_BIT_KHR** specifies the miss stage.
• **VK_SHADER_STAGE_INTERSECTION_BIT_KHR** specifies the intersection stage.
• **VK_SHADER_STAGE_CALLABLE_BIT_KHR** specifies the callable stage.

**Note**

**VK_SHADER_STAGE_ALL_GRAPHICS** only includes the original five graphics stages included in Vulkan 1.0, and not any stages added by extensions. Thus, it may not have the desired effect in all cases.

```c
typedef VkFlags VkShaderStageFlags;
```

*VkShaderStageFlags* is a bitmask type for setting a mask of zero or more *VkShaderStageFlagBits*.

The *VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT* structure is defined as:

```c
typedef struct VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT {
    VkStructureType    sType;
    void*              pNext;
    uint32_t           requiredSubgroupSize;
} VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT;
```

• **sType** is the type of this structure.
• **pNext** is NULL or a pointer to an extension-specific structure.
• **requiredSubgroupSize** is an unsigned integer value that specifies the required subgroup size for the newly created pipeline shader stage.

**Valid Usage**

• **requiredSubgroupSize** must be a power-of-two integer
• **requiredSubgroupSize** must be greater or equal to **minSubgroupSize**
• **requiredSubgroupSize** must be less than or equal to **maxSubgroupSize**

If a *VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT* structure is included in the **pNext** chain of *VkPipelineShaderStageCreateInfo*, it specifies that the pipeline shader stage being compiled has a required subgroup size.

**Valid Usage (Implicit)**

• **sType** must be

  ```c
  VK_STRUCTURE_TYPE_PIPELINE_SHADER_STAGE_REQUIRED_SUBGROUP_SIZE_CREATE_INFO_EXT
  ```
9.2. Graphics Pipelines

Graphics pipelines consist of multiple shader stages, multiple fixed-function pipeline stages, and a pipeline layout.

To create graphics pipelines, call:

```c
VkResult vkCreateGraphicsPipelines(
    VkDevice                                    device,                     
    VkPipelineCache                             pipelineCache,             
    uint32_t                                    createInfoCount,           
    const VkGraphicsPipelineCreateInfo*         pCreateInfos,             
    const VkAllocationCallbacks*                pAllocator,                
    VkPipeline*                                 pPipelines);                 
```

- **device** is the logical device that creates the graphics pipelines.
- **pipelineCache** is either **VK_NULL_HANDLE**, indicating that pipeline caching is disabled; or the handle of a valid pipeline cache object, in which case use of that cache is enabled for the duration of the command.
- **createInfoCount** is the length of the **pCreateInfos** and **pPipelines** arrays.
- **pCreateInfos** is a pointer to an array of **VkGraphicsPipelineCreateInfo** structures.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pPipelines** is a pointer to an array of **VkPipeline** handles in which the resulting graphics pipeline objects are returned.

The **VkGraphicsPipelineCreateInfo** structure includes an array of shader create info structures containing all the desired active shader stages, as well as creation info to define all relevant fixed-function stages, and a pipeline layout.

---

**Valid Usage**

- If the **flags** member of any element of **pCreateInfos** contains the **VK_PIPELINE_CREATE_DERIVATIVE_BIT** flag, and the **basePipelineIndex** member of that same element is not -1, **basePipelineIndex** must be less than the index into **pCreateInfos** that corresponds to that element.

- If the **flags** member of any element of **pCreateInfos** contains the **VK_PIPELINE_CREATE_DERIVATIVE_BIT** flag, the base pipeline must have been created with the **VK_PIPELINE_CREATE_ALLOW_DERIVATIVES_BIT** flag set.

- If **pipelineCache** was created with **VK_PIPELINE_CACHE_CREATE_EXTERNALLY_SYNCHRONIZED_BIT_EXT**, host access to **pipelineCache** must be externally synchronized.
Note

An implicit cache may be provided by the implementation or a layer. For this reason, it is still valid to set `VK_PIPELINE_CREATE_FAIL_ON_PIPELINE_COMPILE_REQUIRED_BIT_EXT` on `flags` for any element of `pCreateInfos` while passing `VK_NULL_HANDLE` for `pipelineCache`.

Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- If `pipelineCache` is not `VK_NULL_HANDLE`, `pipelineCache` must be a valid `VkPipelineCache` handle
- `pCreateInfos` must be a valid pointer to an array of `createInfoCount` valid `VkGraphicsPipelineCreateInfo` structures
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- `pPipelines` must be a valid pointer to an array of `createInfoCount` `VkPipeline` handles
- `createInfoCount` must be greater than 0
- If `pipelineCache` is a valid handle, it must have been created, allocated, or retrieved from `device`

Return Codes

Success

- `VK_SUCCESS`
- `VK_PIPELINE_COMPILE_REQUIRED_EXT`

Failure

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`
- `VK_ERROR_INVALID_SHADER_NV`

The `VkGraphicsPipelineCreateInfo` structure is defined as:
typedef struct VkGraphicsPipelineCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkPipelineCreateFlags flags;
    uint32_t stageCount;
    const VkPipelineShaderStageCreateInfo* pStages;
    const VkPipelineVertexInputStateCreateInfo* pVertexInputState;
    const VkPipelineInputAssemblyStateCreateInfo* pInputAssemblyState;
    const VkPipelineTessellationStateCreateInfo* pTessellationState;
    const VkPipelineViewportStateCreateInfo* pViewportState;
    const VkPipelineRasterizationStateCreateInfo* pRasterizationState;
    const VkPipelineMultisampleStateCreateInfo* pMultisampleState;
    const VkPipelineDepthStencilStateCreateInfo* pDepthStencilState;
    const VkPipelineColorBlendStateCreateInfo* pColorBlendState;
    const VkPipelineDynamicStateCreateInfo* pDynamicState;
    VkPipelineLayout layout;
    VkRenderPass renderPass;
    uint32_t subpass;
    VkPipeline basePipelineHandle;
    int32_t basePipelineIndex;
} VkGraphicsPipelineCreateInfo;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **flags** is a bitmask of VkPipelineCreateFlagBits specifying how the pipeline will be generated.
- **stageCount** is the number of entries in the **pStages** array.
- **pStages** is a pointer to an array of **stageCount** VkPipelineShaderStageCreateInfo structures describing the set of the shader stages to be included in the graphics pipeline.
- **pVertexInputState** is a pointer to a VkPipelineVertexInputStateCreateInfo structure. It is ignored if the pipeline includes a mesh shader stage.
- **pInputAssemblyState** is a pointer to a VkPipelineInputAssemblyStateCreateInfo structure which determines input assembly behavior, as described in Drawing Commands. It is ignored if the pipeline includes a mesh shader stage.
- **pTessellationState** is a pointer to a VkPipelineTessellationStateCreateInfo structure, and is ignored if the pipeline does not include a tessellation control shader stage and tessellation evaluation shader stage.
- **pViewportState** is a pointer to a VkPipelineViewportStateCreateInfo structure, and is ignored if the pipeline has rasterization disabled.
- **pRasterizationState** is a pointer to a VkPipelineRasterizationStateCreateInfo structure.
- **pMultisampleState** is a pointer to a VkPipelineMultisampleStateCreateInfo structure, and is ignored if the pipeline has rasterization disabled.
- **pDepthStencilState** is a pointer to a VkPipelineDepthStencilStateCreateInfo structure, and is ignored if the pipeline has rasterization disabled or if the subpass of the render pass the pipeline is created against does not use a depth/stencil attachment.
• **pColorBlendState** is a pointer to a `VkPipelineColorBlendStateCreateInfo` structure, and is ignored if the pipeline has rasterization disabled or if the subpass of the render pass the pipeline is created against does not use any color attachments.

• **pDynamicState** is a pointer to a `VkPipelineDynamicStateCreateInfo` structure, and is used to indicate which properties of the pipeline state object are dynamic and can be changed independently of the pipeline state. This can be **NULL**, which means no state in the pipeline is considered dynamic.

• **layout** is the description of binding locations used by both the pipeline and descriptor sets used with the pipeline.

• **renderPass** is a handle to a render pass object describing the environment in which the pipeline will be used; the pipeline **must** only be used with an instance of any render pass compatible with the one provided. See **Render Pass Compatibility** for more information.

• **subpass** is the index of the subpass in the render pass where this pipeline will be used.

• **basePipelineHandle** is a pipeline to derive from.

• **basePipelineIndex** is an index into the **pCreateInfos** parameter to use as a pipeline to derive from.

The parameters **basePipelineHandle** and **basePipelineIndex** are described in more detail in **Pipeline Derivatives**.

If any shader stage fails to compile, the compile log will be reported back to the application, and **VK_ERROR_INVALID_SHADER_NV** will be generated.
Valid Usage

• If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineIndex` is -1, `basePipelineHandle` must be a valid handle to a graphics `VkPipeline`.

• If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineHandle` is `VK_NULL_HANDLE`, `basePipelineIndex` must be a valid index into the calling command's `pCreateInfos` parameter.

• If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineIndex` is not -1, `basePipelineHandle` must be `VK_NULL_HANDLE`.

• If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineHandle` is not `VK_NULL_HANDLE`, `basePipelineIndex` must be -1.

• The `stage` member of each element of `pStages` must be unique.

• The geometric shader stages provided in `pStages` must be either from the mesh shading pipeline (`stage` is `VK_SHADER_STAGE_TASK_BIT_NV` or `VK_SHADER_STAGE_MESH_BIT_NV`) or from the primitive shading pipeline (`stage` is `VK_SHADER_STAGE_VERTEX_BIT`, `VK_SHADER_STAGE_TESSELLATION_CONTROL_BIT`, `VK_SHADER_STAGE_TESSELLATION_EVALUATION_BIT`, or `VK_SHADER_STAGE_GEOMETRY_BIT`).

• The `stage` member of one element of `pStages` must be either `VK_SHADER_STAGE_VERTEX_BIT` or `VK_SHADER_STAGE_MESH_BIT_NV`.

• The `stage` member of each element of `pStages` must not be `VK_SHADER_STAGE_COMPUTE_BIT`.

• If `pStages` includes a tessellation control shader stage, it must include a tessellation evaluation shader stage.

• If `pStages` includes a tessellation evaluation shader stage, it must include a tessellation control shader stage.

• If `pStages` includes a tessellation control shader stage and a tessellation evaluation shader stage, `pTessellationState` must be a valid pointer to a valid `VkPipelineTessellationStateCreateInfo` structure.

• If `pStages` includes tessellation shader stages, the shader code of at least one stage must contain an `OpExecutionMode` instruction that specifies the type of subdivision in the pipeline.

• If `pStages` includes tessellation shader stages, and the shader code of both stages contain an `OpExecutionMode` instruction that specifies the type of subdivision in the pipeline, they must both specify the same subdivision mode.

• If `pStages` includes tessellation shader stages, the shader code of at least one stage must contain an `OpExecutionMode` instruction that specifies the output patch size in the pipeline.

• If `pStages` includes tessellation shader stages, and the shader code of both contain an `OpExecutionMode` instruction that specifies the out patch size in the pipeline, they must both specify the same patch size.

• If `pStages` includes tessellation shader stages, the `topology` member of `pInputAssembly` must be `VK_PRIMITIVE_TOPOLOGY_PATCH_LIST`.

• If the `topology` member of `pInputAssembly` is `VK_PRIMITIVE_TOPOLOGY_PATCH_LIST`, `pStages`...
must include tessellation shader stages

- If pStages includes a geometry shader stage, and does not include any tessellation shader stages, its shader code must contain an OpExecutionMode instruction that specifies an input primitive type that is compatible with the primitive topology specified in pInputAssembly.

- If pStages includes a geometry shader stage, and also includes tessellation shader stages, its shader code must contain an OpExecutionMode instruction that specifies an input primitive type that is compatible with the primitive topology that is output by the tessellation stages.

- If pStages includes a fragment shader stage and a geometry shader stage, and the fragment shader code reads from an input variable that is decorated with PrimitiveID, then the geometry shader code must write to a matching output variable, decorated with PrimitiveID, in all execution paths.

- If pStages includes a fragment shader stage, its shader code must not read from any input attachment that is defined as VK_ATTACHMENT_UNUSED in subpass.

The shader code for the entry points identified by pStages, and the rest of the state identified by this structure must adhere to the pipeline linking rules described in the Shader Interfaces chapter.

- If rasterization is not disabled and subpass uses a depth/stencil attachment in renderPass that has a layout of VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL or VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL in the VkAttachmentReference defined by subpass, the depthWriteEnable member of pDepthStencilState must be VK_FALSE.

- If rasterization is not disabled and subpass uses a depth/stencil attachment in renderPass that has a layout of VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL or VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL in the VkAttachmentReference defined by subpass, the failOp, passOp and depthFailOp members of each of the front and back members of pDepthStencilState must be VK_STENCIL_OP_KEEP.

- If rasterization is not disabled and the subpass uses color attachments, then for each color attachment in the subpass the blendEnable member of the corresponding element of the pAttachment member of pColorBlendState must be VK_FALSE if the attached image’s format features does not contain VK_FORMAT_FEATURE_COLOR_ATTACHMENT_BLEND_BIT.

- If rasterization is not disabled and the subpass uses color attachments, the attachmentCount member of pColorBlendState must be equal to the colorAttachmentCount used to create subpass.

- If no element of the pDynamicStates member of pDynamicState is VK_DYNAMIC_STATE_VIEWPORT, the pViewports member of pViewportState must be a valid pointer to an array of pViewportState->viewportCount valid VkViewport structures.

- If no element of the pDynamicStates member of pDynamicState is VK_DYNAMIC_STATE_SCISSOR, the pScissors member of pViewportState must be a valid pointer to an array of pViewportState->scissorCount VkRect2D structures.

- If the wide lines feature is not enabled, and no element of the pDynamicStates member of pRasterizationState is VK_DYNAMIC_STATE_LINE_WIDTH, the lineWidth member of pRasterizationState must be 1.0.

- If the rasterizerDiscardEnable member of pRasterizationState is VK_FALSE, pViewportState
must be a valid pointer to a valid VkPipelineViewportStateCreateInfo structure

- If the rasterizerDiscardEnable member of pRasterizationState is VK_FALSE, pMultisampleState must be a valid pointer to a valid VkPipelineMultisampleStateCreateInfo structure

- If the rasterizerDiscardEnable member of pRasterizationState is VK_FALSE, and subpass uses a depth/stencil attachment, pDepthStencilState must be a valid pointer to a valid VkPipelineDepthStencilStateCreateInfo structure

- If the rasterizerDiscardEnable member of pRasterizationState is VK_FALSE, and subpass uses color attachments, pColorBlendState must be a valid pointer to a valid VkPipelineColorBlendStateCreateInfo structure

- If the depth bias clamping feature is not enabled, no element of the pDynamicStates member of pDynamicState is VK_DYNAMIC_STATE_DEPTH_BIAS, and the depthBiasEnable member of pRasterizationState is VK_TRUE, the depthBiasClamp member of pRasterizationState must be 0.0

- If the VK_EXT_depth_range_unrestricted extension is not enabled and no element of the pDynamicStates member of pDynamicState is VK_DYNAMIC_STATE_DEPTH_BOUNDS, and the depthBoundsTestEnable member of pDepthStencilState is VK_TRUE, the minDepthBounds and maxDepthBounds members of pDepthStencilState must be between 0.0 and 1.0, inclusive

- If no element of the pDynamicStates member of pDynamicState is VK_DYNAMIC_STATE_SAMPLE_LOCATIONS_EXT, and the sampleLocationsEnable member of a VkPipelineSampleLocationsStateCreateInfoEXT structure included in the pNext chain of pMultisampleState is VK_TRUE, the sampleLocationsInfo.sampleLocationGridSize.width must evenly divide VkMultisamplePropertiesEXT::sampleLocationGridSize.width as returned by vkGetPhysicalDeviceMultisamplePropertiesEXT with a samples parameter equaling rasterizationSamples

- If no element of the pDynamicStates member of pDynamicState is VK_DYNAMIC_STATE_SAMPLE_LOCATIONS_EXT, and the sampleLocationsEnable member of a VkPipelineSampleLocationsStateCreateInfoEXT structure included in the pNext chain of pMultisampleState is VK_TRUE, the sampleLocationsInfo.sampleLocationGridSize.height must evenly divide VkMultisamplePropertiesEXT::sampleLocationGridSize.height as returned by vkGetPhysicalDeviceMultisamplePropertiesEXT with a samples parameter equaling rasterizationSamples

- If no element of the pDynamicStates member of pDynamicState is VK_DYNAMIC_STATE_SAMPLE_LOCATIONS_EXT, and the sampleLocationsEnable member of a VkPipelineSampleLocationsStateCreateInfoEXT structure included in the pNext chain of pMultisampleState is VK_TRUE, the sampleLocationsInfo.sampleLocationsPerPixel must equal rasterizationSamples

- If the sampleLocationsEnable member of a VkPipelineSampleLocationsStateCreateInfoEXT structure included in the pNext chain of pMultisampleState is VK_TRUE, the fragment shader code must not statically use the extended instruction InterpolateAtSample

- layout must be consistent with all shaders specified in pStages

- If neither the VK_AMD_mixed_attachment_samples nor the VK_NV_framebuffer_mixed_samples extensions are enabled, and if subpass uses color and/or depth/stencil attachments, then the rasterizationSamples member of pMultisampleState must be the same as the sample
count for those subpass attachments

- If the VK_AMD_mixed_attachment_samples extension is enabled, and if subpass uses color and/or depth/stencil attachments, then the rasterizationSamples member of pMultisampleState must equal the maximum of the sample counts of those subpass attachments.

- If the VK_NV_framebuffer_mixed_samples extension is enabled, and if subpass has a depth/stencil attachment and depth test, stencil test, or depth bounds test are enabled, then the rasterizationSamples member of pMultisampleState must be the same as the sample count of the depth/stencil attachment.

- If the VK_NV_framebuffer_mixed_samples extension is enabled, and if subpass has any color attachments, then the rasterizationSamples member of pMultisampleState must be greater than or equal to the sample count for those subpass attachments.

- If the VK_NV_coverage_reduction_mode extension is enabled, the coverage reduction mode specified by VkPipelineCoverageReductionStateCreateInfoNV::coverageReductionMode, the rasterizationSamples member of pMultisampleState and the sample counts for the color and depth/stencil attachments (if the subpass has them) must be a valid combination returned by vkGetPhysicalDeviceSupportedFramebufferMixedSamplesCombinationsNV.

- If subpass does not use any color and/or depth/stencil attachments, then the rasterizationSamples member of pMultisampleState must follow the rules for a zero-attachment subpass.

- subpass must be a valid subpass within renderPass.

- If the renderPass has multiview enabled and subpass has more than one bit set in the view mask and multiviewTessellationShader is not enabled, then pStages must not include tessellation shaders.

- If the renderPass has multiview enabled and subpass has more than one bit set in the view mask and multiviewGeometryShader is not enabled, then pStages must not include a geometry shader.

- If the renderPass has multiview enabled and subpass has more than one bit set in the view mask, shaders in the pipeline must not write to the Layer built-in output.

- If the renderPass has multiview enabled, all shaders must not include variables decorated with the Layer built-in decoration in their interfaces.

- flags must not contain the VK_PIPELINE_CREATE_DISPATCH_BASE flag.

- If pStages includes a fragment shader stage and an input attachment was referenced by an aspectMask at renderPass creation time, its shader code must only read from the aspects that were specified for that input attachment.

- The number of resources in layout accessible to each shader stage that is used by the pipeline must be less than or equal to VkPhysicalDeviceLimits::maxPerStageResources.

- If no element of the pDynamicStates member of pDynamicState is VK_DYNAMIC_STATE_VIEWPORT_W_SCALING_NV, and the viewportWScalingEnable member of a VkPipelineViewportWScalingStateCreateInfoNV structure, included in the pNext chain of pViewportState, is VK_TRUE, the pViewportWScalings member of the VkPipelineViewportWScalingStateCreateInfoNV must be a pointer to an array of...
If `pStages` includes a vertex shader stage, `pVertexInputState` must be a valid pointer to a valid `VkPipelineVertexInputStateCreateInfo` structure.

If `pStages` includes a vertex shader stage, `pInputAssemblyState` must be a valid pointer to a valid `VkPipelineInputAssemblyStateCreateInfo` structure.

The Xfb execution mode can be specified by only one shader stage in `pStages`.

If any shader stage in `pStages` specifies Xfb execution mode it must be the last vertex processing stage.

If a `VkPipelineRasterizationStateStreamCreateInfoEXT::rasterizationStream` value other than zero is specified, all variables in the output interface of the entry point being compiled decorated with `Position`, `PointSize`, `ClipDistance`, or `CullDistance` must all be decorated with identical `Stream` values that match the `rasterizationStream`.

If `VkPipelineRasterizationStateStreamCreateInfoEXT::rasterizationStream` is zero, or not specified, all variables in the output interface of the entry point being compiled decorated with `Position`, `PointSize`, `ClipDistance`, or `CullDistance` must all be decorated with a `Stream` value of zero, or must not specify the `Stream` decoration.

If the last vertex processing stage is a geometry shader, and that geometry shader uses the `GeometryStreams` capability, then `VkPhysicalDeviceTransformFeedbackFeaturesEXT::geometryStreams` feature must be enabled.

If there are any mesh shader stages in the pipeline there must not be any shader stage in the pipeline with a Xfb execution mode.

If the `lineRasterizationMode` member of a `VkPipelineRasterizationLineStateCreateInfoEXT` structure included in the `pNext` chain of `pRasterizationState` is `VK_LINE_RASTERIZATION_MODE_BRESENHAM_EXT` or `VK_LINE_RASTERIZATION_MODE_RECTANGULAR_SMOOTH_EXT` and if rasterization is enabled, then the `alphaToCoverageEnable`, `alphaToOneEnable`, and `sampleShadingEnable` members of `pMultisampleState` all be `VK_FALSE`.

If the `stippledLineEnable` member of `VkPipelineRasterizationLineStateCreateInfoEXT` is `VK_TRUE` and no element of the `pDynamicStates` member of `pDynamicState` is `VK_DYNAMIC_STATE_LINE_STIPPLE_EXT`, then the `lineStippleFactor` member of `VkPipelineRasterizationLineStateCreateInfoEXT` must be in the range [1,256].

Flags must not include `VK_PIPELINE_CREATE_LIBRARY_BIT_KHR`.

Flags must not include `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_ANY_HIT_SHADERS_BIT_KHR`.

Flags must not include `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_CLOSEST_HIT_SHADERS_BIT_KHR`.

Flags must not include `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_MISS_SHADERS_BIT_KHR`.

Flags must not include `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_INTERSECTION_SHADERS_BIT_KHR`.

Flags must not include `VK_PIPELINE_CREATE_RAY_TRACING_SKIP_TRIANGLES_BIT_KHR`.

Flags must not include `VK_PIPELINE_CREATE_RAY_TRACING_SKIP_AABBS_BIT_KHR`.
• If `flags` includes `VK_PIPELINE_CREATE_INDIRECT_BINDABLE_BIT_NV`, then the `VkPhysicalDeviceDeviceGeneratedCommandsFeaturesNV::deviceGeneratedCommands` feature must be enabled.

• If `flags` includes `VK_PIPELINE_CREATE_INDIRECT_BINDABLE_BIT_NV`, then all stages must not specify Xfb execution mode.

• If the `pipelineCreationCacheControl` feature is not enabled, `flags` must not include `VK_PIPELINE_CREATE_FAIL_ON_PIPELINE_COMPILE_REQUIRED_BIT_EXT` or `VK_PIPELINE_CREATE_EARLY_RETURN_ON_FAILURE_BIT_EXT`.

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_GRAPHICS_PIPELINE_CREATE_INFO`.
- Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkGraphicsPipelineShaderGroupsCreateInfoNV`, `VkPipelineCompilerControlCreateInfoAMD`, `VkPipelineCreationFeedbackCreateInfoEXT`, `VkPipelineDiscardRectangleStateCreateInfoEXT`, or `VkPipelineRepresentativeFragmentTestStateCreateInfoNV`.
- The `sType` value of each struct in the `pNext` chain must be unique.
- `flags` must be a valid combination of `VkPipelineCreateFlagBits` values.
- `pStages` must be a valid pointer to an array of `stageCount` valid `VkPipelineShaderStageCreateInfo` structures.
- `pRasterizationState` must be a valid pointer to a valid `VkPipelineRasterizationStateCreateInfo` structure.
- If `pDynamicState` is not `NULL`, `pDynamicState` must be a valid pointer to a valid `VkPipelineDynamicStateCreateInfo` structure.
- `layout` must be a valid `VkPipelineLayout` handle.
- `renderPass` must be a valid `VkRenderPass` handle.
- `stageCount` must be greater than 0.
- Each of `basePipelineHandle`, `layout`, and `renderPass` that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`.

Possible values of the `flags` member of `VkGraphicsPipelineCreateInfo`, `VkRayTracingPipelineCreateInfoKHR`, `VkRayTracingPipelineCreateInfoNV`, and `VkComputePipelineCreateInfo`, specifying how a pipeline is created, are:
typedef enum VkPipelineCreateFlagBits {
    VK_PIPELINE_CREATE_DISABLE_OPTIMIZATION_BIT = 0x00000001,
    VK_PIPELINE_CREATE_ALLOW_DERIVATIVES_BIT = 0x00000002,
    VK_PIPELINE_CREATE_DERIVATIVE_BIT = 0x00000004,
    VK_PIPELINE_CREATE_VIEW_INDEX_FROM_DEVICE_INDEX_BIT = 0x00000008,
    VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_ANY_HIT_SHADERS_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_CLOSEST_HIT_SHADERS_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_MISS_SHADERS_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_INTERSECTION_SHADERS_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_RAY_TRACING_SKIP_TRIANGLES_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_RAY_TRACING_SKIP_AABBS_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_DEFER_COMPILE_BIT_NV = 0x00000000,
    VK_PIPELINE_CREATE_CAPTURE_STATISTICS_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_CAPTURE_INTERNAL_REPRESENTATIONS_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_INDIRECT_BINDABLE_BIT_NV = 0x00000000,
    VK_PIPELINE_CREATE_LIBRARY_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_FAIL_ON_PIPELINE_COMPILE_REQUIRED_BIT_EXT = 0x00000000,
    VK_PIPELINE_CREATE_EARLY_RETURN_ON_FAILURE_BIT_EXT = 0x00000000,
    VK_PIPELINE_CREATE_DISPATCH_BASE_KHR = 0x00000000,
    VK_PIPELINE_CREATE_VIEW_INDEX_FROM_DEVICE_INDEX_BIT_KHR = 0x00000000,
    VK_PIPELINE_CREATE_DISPATCH_BASE_KHR = 0x00000000,
} VkPipelineCreateFlagBits;

- **VK_PIPELINE_CREATE_DISABLE_OPTIMIZATION_BIT** specifies that the created pipeline will not be optimized. Using this flag may reduce the time taken to create the pipeline.

- **VK_PIPELINE_CREATE_ALLOW_DERIVATIVES_BIT** specifies that the pipeline to be created is allowed to be the parent of a pipeline that will be created in a subsequent pipeline creation call.

- **VK_PIPELINE_CREATE_DERIVATIVE_BIT** specifies that the pipeline to be created will be a child of a previously created parent pipeline.

- **VK_PIPELINE_CREATE_VIEW_INDEX_FROM_DEVICE_INDEX_BIT** specifies that any shader input variables decorated as `ViewIndex` will be assigned values as if they were decorated as `DeviceIndex`.

- **VK_PIPELINE_CREATE_DISPATCH_BASE** specifies that a compute pipeline can be used with `vkCmdDispatchBase` with a non-zero base workgroup.

- **VK_PIPELINE_CREATE_DEFER_COMPILE_BIT_NV** specifies that a pipeline is created with all shaders in the deferred state. Before using the pipeline the application must call `vkCompileDeferredNV` exactly once on each shader in the pipeline before using the pipeline.

- **VK_PIPELINE_CREATE_CAPTURE_STATISTICS_BIT_KHR** specifies that the shader compiler should capture statistics for the executables produced by the compile process which can later be retrieved by calling `vkGetPipelineExecutableStatisticsKHR`. Enabling this flag must not affect the final compiled pipeline but may disable pipeline caching or otherwise affect pipeline creation time.

- **VK_PIPELINE_CREATE_CAPTURE_INTERNAL_REPRESENTATIONS_BIT_KHR** specifies that the shader compiler should capture the internal representations of executables produced by the compile process which can later be retrieved by calling...
vkGetPipelineExecutableInternalRepresentationsKHR. Enabling this flag must not affect the final compiled pipeline but may disable pipeline caching or otherwise affect pipeline creation time.

- **VK_PIPELINE_CREATE_LIBRARY_BIT_KHR** specifies that the pipeline cannot be used directly, and instead defines a pipeline library that can be combined with other pipelines using the VkPipelineLibraryCreateInfoKHR structure. This is available in raytracing pipelines.

- **VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_ANY_HIT_SHADERS_BIT_KHR** specifies that an any hit shader will always be present when an any hit shader would be executed.

- **VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_CLOSEST_HIT_SHADERS_BIT_KHR** specifies that a closest hit shader will always be present when a closest hit shader would be executed.

- **VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_MISS_SHADERS_BIT_KHR** specifies that a miss shader will always be present when a miss shader would be executed.

- **VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_INTERSECTION_SHADERS_BIT_KHR** specifies that an intersection shader will always be present when an intersection shader would be executed.

- **VK_PIPELINE_CREATE_RAY_TRACING_SKIP_TRIANGLES_BIT_KHR** specifies that triangle primitives will be skipped during traversal using OpTraceKHR.

- **VK_PIPELINE_CREATE_RAY_TRACING_SKIP_AABBS_BIT_KHR** specifies that AABB primitives will be skipped during traversal using OpTraceKHR.

- **VK_PIPELINE_CREATE_INDIRECT_BINDABLE_BIT_NV** specifies that the pipeline can be used in combination with Device-Generated Commands.

- **VK_PIPELINE_CREATE_FAIL_ON_PIPELINE_COMPILE_REQUIRED_BIT_EXT** specifies that pipeline creation will fail if a compile is required for creation of a valid VkPipeline object; VK_PIPELINE_COMPILEREQUIRED_EXT will be returned by pipeline creation, and the VkPipeline will be set to VK_NULL_HANDLE.

- When creating multiple pipelines, **VK_PIPELINE_CREATE_EARLY_RETURN_ON_FAILURE_BIT_EXT** specifies that control will be returned to the application on failure of the corresponding pipeline rather than continuing to create additional pipelines.

It is valid to set both **VK_PIPELINE_CREATE_ALLOW_DERIVATIVES_BIT** and **VK_PIPELINE_CREATE_DERIVATIVE_BIT**. This allows a pipeline to be both a parent and possibly a child in a pipeline hierarchy. See Pipeline Derivatives for more information.

```c
typedef VkFlags VkPipelineCreateFlags;
```

**VkPipelineCreateFlags** is a bitmask type for setting a mask of zero or more VkPipelineCreateFlagBits.

The **VkPipelineDynamicStateCreateInfo** structure is defined as:
typedef struct VkPipelineDynamicStateCreateInfo {
    VkStructureType                      sType;
    const void*                          pNext;
    VkPipelineDynamicStateCreateFlags    flags;
    uint32_t                             dynamicStateCount;
    const VkDynamicState*                pDynamicStates;
} VkPipelineDynamicStateCreateInfo;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `flags` is reserved for future use.
- `dynamicStateCount` is the number of elements in the `pDynamicStates` array.
- `pDynamicStates` is a pointer to an array of `VkDynamicState` values specifying which pieces of pipeline state will use the values from dynamic state commands rather than from pipeline state creation info.

### Valid Usage

- Each element of `pDynamicStates` **must** be unique

### Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_PIPELINE_DYNAMIC_STATE_CREATE_INFO`
- `pNext` **must** be `NULL`
- `flags` **must** be `0`
- If `dynamicStateCount` is not `0`, `pDynamicStates` **must** be a valid pointer to an array of `dynamicStateCount` valid `VkDynamicState` values

typedef VkFlags VkPipelineDynamicStateCreateFlags;

`VkPipelineDynamicStateCreateFlags` is a bitmask type for setting a mask, but is currently reserved for future use.

The source of different pieces of dynamic state is specified by the `VkPipelineDynamicStateCreateInfo: :pDynamicStates` property of the currently active pipeline, each of whose elements **must** be one of the values:
```c
typedef enum VkDynamicState {
    VK_DYNAMIC_STATE_VIEWPORT = 0,
    VK_DYNAMIC_STATE_SCISSOR = 1,
    VK_DYNAMIC_STATE_LINE_WIDTH = 2,
    VK_DYNAMIC_STATE_DEPTH_BIAS = 3,
    VK_DYNAMIC_STATE_BLEND_CONSTANTS = 4,
    VK_DYNAMIC_STATE_DEPTH_BOUNDS = 5,
    VK_DYNAMIC_STATE_STENCIL_COMPARE_MASK = 6,
    VK_DYNAMIC_STATE_STENCIL_WRITE_MASK = 7,
    VK_DYNAMIC_STATE_STENCIL_REFERENCE = 8,
    VK_DYNAMIC_STATE_VIEWPORT_W_SCALING_NV = 1000087000,
    VK_DYNAMIC_STATE_DISCARD_RECTANGLE_EXT = 1000099000,
    VK_DYNAMIC_STATE_SAMPLE_LOCATIONS_EXT = 1000143000,
    VK_DYNAMIC_STATE_VIEWPORT_SHADING_RATE_PALETTE_NV = 1000164004,
    VK_DYNAMIC_STATE_VIEWPORT_COARSE_SAMPLE_ORDER_NV = 1000164006,
    VK_DYNAMIC_STATE_EXCLUSIVE_SCISSOR_NV = 1000205001,
    VK_DYNAMIC_STATE_LINE_STIPPLE_EXT = 1000259000,
} VkDynamicState;
```

- **VK_DYNAMIC_STATE_VIEWPORT** specifies that the `pViewports` state in `VkPipelineViewportStateCreateInfo` will be ignored and must be set dynamically with `vkCmdSetViewport` before any draw commands. The number of viewports used by a pipeline is still specified by the `viewportCount` member of `VkPipelineViewportStateCreateInfo`.

- **VK_DYNAMIC_STATE_SCISSOR** specifies that the `pScissors` state in `VkPipelineViewportStateCreateInfo` will be ignored and must be set dynamically with `vkCmdSetScissor` before any draw commands. The number of scissor rectangles used by a pipeline is still specified by the `scissorCount` member of `VkPipelineViewportStateCreateInfo`.

- **VK_DYNAMIC_STATE_LINE_WIDTH** specifies that the `lineWidth` state in `VkPipelineRasterizationStateCreateInfo` will be ignored and must be set dynamically with `vkCmdSetLineWidth` before any draw commands that generate line primitives for the rasterizer.

- **VK_DYNAMIC_STATE_DEPTH_BIAS** specifies that the `depthBiasConstantFactor`, `depthBiasClamp` and `depthBiasSlopeFactor` states in `VkPipelineRasterizationStateCreateInfo` will be ignored and must be set dynamically with `vkCmdSetDepthBias` before any draws are performed with `depthBiasEnable` in `VkPipelineRasterizationStateCreateInfo` set to `VK_TRUE`.

- **VK_DYNAMIC_STATE_BLEND_CONSTANTS** specifies that the `blendConstants` state in `VkPipelineColorBlendStateCreateInfo` will be ignored and must be set dynamically with `vkCmdSetBlendConstants` before any draws are performed with a pipeline state with `VkPipelineColorBlendAttachmentState` member `blendEnable` set to `VK_TRUE` and any of the blend functions using a constant blend color.

- **VK_DYNAMIC_STATE_DEPTH_BOUNDS** specifies that the `minDepthBounds` and `maxDepthBounds` states of `VkPipelineDepthStencilStateCreateInfo` will be ignored and must be set dynamically with `vkCmdSetDepthBounds` before any draws are performed with a pipeline state with `VkPipelineDepthStencilStateCreateInfo` member `depthBoundsTestEnable` set to `VK_TRUE`.

- **VK_DYNAMIC_STATE_STENCIL_COMPARE_MASK** specifies that the `compareMask` state in `VkPipelineColorBlendAttachmentState` member `blendEnable` set to `VK_TRUE` and any of the blend functions using a constant blend color.
**VkPipelineDepthStencilStateCreateInfo** for both **front** and **back** will be ignored and **must** be set dynamically with **vkCmdSetStencilCompareMask** before any draws are performed with a pipeline state with **VkPipelineDepthStencilStateCreateInfo** member **stencilTestEnable** set to **VK_TRUE**

- **VK_DYNAMIC_STATE_STENCIL_WRITE_MASK** specifies that the **writeMask** state in **VkPipelineDepthStencilStateCreateInfo** for both **front** and **back** will be ignored and **must** be set dynamically with **vkCmdSetStencilWriteMask** before any draws are performed with a pipeline state with **VkPipelineDepthStencilStateCreateInfo** member **stencilTestEnable** set to **VK_TRUE**

- **VK_DYNAMIC_STATE_STENCIL_REFERENCE** specifies that the **reference** state in **VkPipelineDepthStencilStateCreateInfo** for both **front** and **back** will be ignored and **must** be set dynamically with **vkCmdSetStencilReference** before any draws are performed with a pipeline state with **VkPipelineDepthStencilStateCreateInfo** member **stencilTestEnable** set to **VK_TRUE**

- **VK_DYNAMIC_STATE_VIEWPORT_W_SCALING_NV** specifies that the **pViewportScalings** state in **VkPipelineViewportWScalingStateCreateInfoNV** will be ignored and **must** be set dynamically with **vkCmdSetViewportWScalingNV** before any draws are performed with a pipeline state with **VkPipelineViewportWScalingStateCreateInfoNV** member **viewportScalingEnable** set to **VK_TRUE**

- **VK_DYNAMIC_STATE_DISCARD_RECTANGLE_EXT** specifies that the **pDiscardRectangles** state in **VkPipelineDiscardRectangleStateCreateInfoEXT** will be ignored and **must** be set dynamically with **vkCmdSetDiscardRectangleEXT** before any draw or clear commands. The **VkDiscardRectangleModeEXT** and the number of active discard rectangles is still specified by the **discardRectangleMode** and **discardRectangleCount** members of **VkPipelineDiscardRectangleStateCreateInfoEXT**.

- **VK_DYNAMIC_STATE_SAMPLE_LOCATIONS_EXT** specifies that the **sampleLocationsInfo** state in **VkPipelineSampleLocationsStateCreateInfoEXT** will be ignored and **must** be set dynamically with **vkCmdSetSampleLocationsEXT** before any draw or clear commands. Enabling custom sample locations is still indicated by the **sampleLocationsEnable** member of **VkPipelineSampleLocationsStateCreateInfoEXT**.

- **VK_DYNAMIC_STATE_EXCLUSIVE_SCISSOR_NV** specifies that the **pExclusiveScissors** state in **VkPipelineViewportExclusiveScissorStateCreateInfoNV** will be ignored and **must** be set dynamically with **vkCmdSetExclusiveScissorNV** before any draw commands. The number of exclusive scissor rectangles used by a pipeline is still specified by the **exclusiveScissorCount** member of **VkPipelineViewportExclusiveScissorStateCreateInfoNV**.

- **VK_DYNAMIC_STATE_VIEWPORT_SHADING_RATE_PALETTE_NV** specifies that the **pShadingRatePalettes** state in **VkPipelineViewportShadingRateImageStateCreateInfoNV** will be ignored and **must** be set dynamically with **vkCmdSetViewportShadingRatePaletteNV** before any draw commands.

- **VK_DYNAMIC_STATE_VIEWPORT_COARSE_SAMPLE_ORDER_NV** specifies that the coarse sample order state in **VkPipelineViewportCoarseSampleOrderStateCreateInfoNV** will be ignored and **must** be set dynamically with **vkCmdSetViewportCoarseSampleOrderNV** before any draw commands.

- **VK_DYNAMIC_STATE_LINE_STIPPLE_EXT** specifies that the **lineStippleFactor** and **lineStipplePattern** state in **VkPipelineRasterizationLineStateCreateInfoEXT** will be ignored and **must** be set dynamically with **vkCmdSetLineStippleEXT** before any draws are performed with a pipeline state with **VkPipelineRasterizationLineStateCreateInfoEXT** member **stippledLineEnable** set to **VK_TRUE**.
9.2.1. Valid Combinations of Stages for Graphics Pipelines

The geometric primitive processing can either be handled on a per primitive basis by the vertex, tessellation, and geometry shader stages, or on a per mesh basis using task and mesh shader stages. If the pipeline includes a mesh shader stage, it uses the mesh pipeline, otherwise it uses the primitive pipeline.

If a task shader is omitted, the task shading stage is skipped.

If tessellation shader stages are omitted, the tessellation shading and fixed-function stages of the pipeline are skipped.

If a geometry shader is omitted, the geometry shading stage is skipped.

If a fragment shader is omitted, fragment color outputs have undefined values, and the fragment depth value is unmodified. This can be useful for depth-only rendering.

Presence of a shader stage in a pipeline is indicated by including a valid \texttt{VkPipelineShaderStageCreateInfo} with \texttt{module} and \texttt{pName} selecting an entry point from a shader module, where that entry point is valid for the stage specified by \texttt{stage}.

Presence of some of the fixed-function stages in the pipeline is implicitly derived from enabled shaders and provided state. For example, the fixed-function tessellator is always present when the pipeline has valid Tessellation Control and Tessellation Evaluation shaders.

For example:

- Depth/stencil-only rendering in a subpass with no color attachments
  - Active Pipeline Shader Stages
    - Vertex Shader
  - Required: Fixed-Function Pipeline Stages
    - \texttt{VkPipelineVertexInputStateCreateInfo}
    - \texttt{VkPipelineInputAssemblyStateCreateInfo}
    - \texttt{VkPipelineViewportStateCreateInfo}
    - \texttt{VkPipelineRasterizationStateCreateInfo}
    - \texttt{VkPipelineMultisampleStateCreateInfo}
    - \texttt{VkPipelineDepthStencilStateCreateInfo}

- Color-only rendering in a subpass with no depth/stencil attachment
  - Active Pipeline Shader Stages
    - Vertex Shader
    - Fragment Shader
  - Required: Fixed-Function Pipeline Stages
    - \texttt{VkPipelineVertexInputStateCreateInfo}
    - \texttt{VkPipelineInputAssemblyStateCreateInfo}
9.2.2. Graphics Pipeline Shader Groups

Graphics pipelines can contain multiple shader groups that can be bound individually. Each shader group behaves as if it was a pipeline using the shader group’s state. When the pipeline is bound by...
regular means, it behaves as if the state of group 0 is active, use
\texttt{vkCmdBindPipelineShaderGroupNV} to bind an individual shader group.

The primary purpose of shader groups is allowing the device to bind different pipeline state using
\textit{Device-Generated Commands}.

The \texttt{VkGraphicsPipelineShaderGroupsCreateInfoNV} structure is defined as:

```c
typedef struct VkGraphicsPipelineShaderGroupsCreateInfoNV {
    VkStructureType                              sType;
    const void*                                   pNext;
    uint32_t                                       groupCount;
    const VkGraphicsShaderGroupCreateInfoNV*     pGroups;
    uint32_t                                       pipelineCount;
    const VkPipeline*                             pPipelines;
} VkGraphicsPipelineShaderGroupsCreateInfoNV;
```

- \texttt{sType} is the type of this structure.
- \texttt{pNext} is NULL or a pointer to an extension-specific structure.
- \texttt{groupCount} is the number of elements in the \texttt{pGroups} array.
- \texttt{pGroups} is an array of \texttt{VkGraphicsShaderGroupCreateInfoNV} values specifying which state of the
  original \texttt{VkGraphicsPipelineCreateInfo} each shader group overrides.
- \texttt{pipelineCount} is the number of elements in the \texttt{pPipelines} array.
- \texttt{pPipelines} is an array of graphics \texttt{VkPipeline}, which are referenced within the created pipeline,
  including all their shader groups.

When referencing shader groups by index, groups defined in the referenced pipelines are treated
as if they were defined as additional entries in \texttt{pGroups}. They are appended in the order they appear
in the \texttt{pPipelines} array and in the \texttt{pGroups} array when those pipelines were defined.

The application must maintain the lifetime of all such referenced pipelines based on the pipelines
that make use of them.
Valid Usage

- `groupCount` must be at least 1 and as maximum `VkPhysicalDeviceDeviceGeneratedCommandsPropertiesNV::maxGraphicsShaderGroupCount`
- The sum of `groupCount` including those groups added from referenced `pPipelines` must also be as maximum `VkPhysicalDeviceDeviceGeneratedCommandsPropertiesNV::maxGraphicsShaderGroupCount`
- The state of the first element of `pGroups` must match its equivalent within the parent's `VkGraphicsPipelineCreateInfo`
- Each element of `pGroups` in combination with the rest of the pipeline state yield a valid state configuration
- All elements of `pGroups` use the same shader stage combinations unless any mesh shader stage is used, then either combination of task and mesh or just mesh shader is valid
- Mesh and regular primitive shading stages cannot be mixed across `pGroups`
- Each element of the `pPipelines` member of `libraries` must have been created with identical state to the pipeline currently created except the state that can be overriden by `VkGraphicsShaderGroupCreateInfoNV`
- The `VkPhysicalDeviceDeviceGeneratedCommandsFeaturesNV::deviceGeneratedCommands` feature must be enabled

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_GRAPHICS_PIPELINE_SHADER_GROUPS_CREATE_INFO_NV`
- `pGroups` must be a valid pointer to an array of `groupCount` valid `VkGraphicsShaderGroupCreateInfoNV` structures
- If `pipelineCount` is not 0, `pPipelines` must be a valid pointer to an array of `pipelineCount` valid `VkPipeline` handles
- `groupCount` must be greater than 0

The `VkGraphicsShaderGroupCreateInfoNV` structure provides the state overrides for each shader group. Each shader group behaves like a pipeline that was created from its state as well as the remaining parent's state. It is defined as:
typedef struct VkGraphicsShaderGroupCreateInfoNV {
    VkStructureType sType;
    const void* pNext;
    uint32_t stageCount;
    const VkPipelineShaderStageCreateInfo* pStages;
    const VkPipelineVertexInputStateCreateInfo* pVertexInputState;
    const VkPipelineTessellationStateCreateInfo* pTessellationState;
} VkGraphicsShaderGroupCreateInfoNV;

* `sType` is the type of this structure.
* `pNext` is `NULL` or a pointer to an extension-specific structure.
* `stageCount` is the number of entries in the `pStages` array.
* `pStages` is an array of size `stageCount` structures of type `VkPipelineShaderStageCreateInfo` describing the set of the shader stages to be included in this shader group.
* `pVertexInputState` is a pointer to an instance of the `VkPipelineVertexInputStateCreateInfo` structure.
* `pTessellationState` is a pointer to an instance of the `VkPipelineTessellationStateCreateInfo` structure, and is ignored if the shader group does not include a tessellation control shader stage and tessellation evaluation shader stage.

**Valid Usage**

- For `stageCount`, the same restrictions as in `VkGraphicsPipelineCreateInfo::stageCount` apply.
- For `pStages`, the same restrictions as in `VkGraphicsPipelineCreateInfo::pStages` apply.
- For `pVertexInputState`, the same restrictions as in `VkGraphicsPipelineCreateInfo::pVertexInputState` apply.
- For `pTessellationState`, the same restrictions as in `VkGraphicsPipelineCreateInfo::pTessellationState` apply.

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_GRAPHICS_SHADER_GROUP_CREATE_INFO_NV`
- `pNext` must be `NULL`
- `pStages` must be a valid pointer to an array of `stageCount` valid `VkPipelineShaderStageCreateInfo` structures
- `stageCount` must be greater than `0`
9.3. Pipeline destruction

To destroy a graphics or compute pipeline, call:

```c
void vkDestroyPipeline(
    VkDevice device,
    VkPipeline pipeline,
    const VkAllocationCallbacks* pAllocator);
```

- **device** is the logical device that destroys the pipeline.
- **pipeline** is the handle of the pipeline to destroy.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.

### Valid Usage

- All submitted commands that refer to `pipeline` must have completed execution
- If `VkAllocationCallbacks` were provided when `pipeline` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `pipeline` was created, `pAllocator` must be NULL

### Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- If `pipeline` is not `VK_NULL_HANDLE`, `pipeline` must be a valid `VkPipeline` handle
- If `pAllocator` is not NULL, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- If `pipeline` is a valid handle, it must have been created, allocated, or retrieved from `device`

### Host Synchronization

- Host access to `pipeline` must be externally synchronized

9.4. Multiple Pipeline Creation

Multiple pipelines can be created simultaneously by passing an array of `VkGraphicsPipelineCreateInfo`, `VkRayTracingPipelineCreateInfoKHR`, `VkRayTracingPipelineCreateInfoNV`, or `VkComputePipelineCreateInfo` structures into the `vkCreateGraphicsPipelines`, `vkCreateRayTracingPipelinesKHR`, `vkCreateRayTracingPipelinesNV`, and `vkCreateComputePipelines` commands, respectively. Applications can group together similar
pipelines to be created in a single call, and implementations are encouraged to look for reuse opportunities within a group-create.

When an application attempts to create many pipelines in a single command, it is possible that some subset may fail creation. In that case, the corresponding entries in the output array will be filled with VK_NULL_HANDLE values. If any pipeline fails creation despite valid arguments (for example, due to out of memory errors), the VkResult code returned by vkCreate*Pipelines will indicate why. The implementation will attempt to create all pipelines, and only return VK_NULL_HANDLE values for those that actually failed.

If creation fails for a pipeline that had VK_PIPELINE_CREATE_EARLY_RETURN_ON_FAILURE_BIT_EXT set, pipelines at an index in the pPipelines array greater than or equal to that of the failing pipeline must be set to VK_NULL_HANDLE.

9.5. Pipeline Derivatives

A pipeline derivative is a child pipeline created from a parent pipeline, where the child and parent are expected to have much commonality. The goal of derivative pipelines is that they be cheaper to create using the parent as a starting point, and that it be more efficient (on either host or device) to switch/bind between children of the same parent.

A derivative pipeline is created by setting the VK_PIPELINE_CREATE_DERIVATIVE_BIT flag in the Vk*PipelineCreateInfo structure. If this is set, then exactly one of basePipelineHandle or basePipelineIndex members of the structure must have a valid handle/index, and specifies the parent pipeline. If basePipelineHandle is used, the parent pipeline must have already been created. If basePipelineIndex is used, then the parent is being created in the same command. VK_NULL_HANDLE acts as the invalid handle for basePipelineHandle, and -1 is the invalid index for basePipelineIndex. If basePipelineIndex is used, the base pipeline must appear earlier in the array. The base pipeline must have been created with the VK_PIPELINE_CREATE_ALLOW_DERIVATIVES_BIT flag set.

9.6. Pipeline Cache

Pipeline cache objects allow the result of pipeline construction to be reused between pipelines and between runs of an application. Reuse between pipelines is achieved by passing the same pipeline cache object when creating multiple related pipelines. Reuse across runs of an application is achieved by retrieving pipeline cache contents in one run of an application, saving the contents, and using them to preinitialize a pipeline cache on a subsequent run. The contents of the pipeline cache objects are managed by the implementation. Applications can manage the host memory consumed by a pipeline cache object and control the amount of data retrieved from a pipeline cache object.

Pipeline cache objects are represented by VkPipelineCache handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkPipelineCache)
```

To create pipeline cache objects, call:
VkResult vkCreatePipelineCache(
    VkDevice                                    device,
    const VkPipelineCacheCreateInfo*            pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkPipelineCache*                            pPipelineCache);

- **device** is the logical device that creates the pipeline cache object.
- **pCreateInfo** is a pointer to a `VkPipelineCacheCreateInfo` structure containing initial parameters for the pipeline cache object.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pPipelineCache** is a pointer to a `VkPipelineCache` handle in which the resulting pipeline cache object is returned.

**Note**
Applications **can** track and manage the total host memory size of a pipeline cache object using the `pAllocator`. Applications **can** limit the amount of data retrieved from a pipeline cache object in `vkGetPipelineCacheData`. Implementations **should** not internally limit the total number of entries added to a pipeline cache object or the total host memory consumed.

Once created, a pipeline cache **can** be passed to the `vkCreateGraphicsPipelines`, `vkCreateRayTracingPipelinesKHR`, `vkCreateRayTracingPipelinesNV`, and `vkCreateComputePipelines` commands. If the pipeline cache passed into these commands is not `VK_NULL_HANDLE`, the implementation will query it for possible reuse opportunities and update it with new content. The use of the pipeline cache object in these commands is internally synchronized, and the same pipeline cache object **can** be used in multiple threads simultaneously.

If **flags** of `pCreateInfo` includes `VK_PIPELINE_CACHE_CREATE_EXTERNALLY_SYNCHRONIZED_BIT_EXT`, all commands that modify the returned pipeline cache object **must** be externally synchronized.

**Note**
Implementations **should** make every effort to limit any critical sections to the actual accesses to the cache, which is expected to be significantly shorter than the duration of the `vkCreate*Pipelines` commands.

**Valid Usage (Implicit)**

- **device** **must** be a valid `VkDevice` handle
- **pCreateInfo** **must** be a valid pointer to a valid `VkPipelineCacheCreateInfo` structure
- If **pAllocator** is not NULL, **pAllocator** **must** be a valid pointer to a valid `VkAllocationCallbacks` structure
- **pPipelineCache** **must** be a valid pointer to a `VkPipelineCache` handle
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

The `VkPipelineCacheCreateInfo` structure is defined as:

```c
typedef struct VkPipelineCacheCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkPipelineCacheCreateFlags flags;
    size_t initialDataSize;
    const void* pInitialData;
} VkPipelineCacheCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkPipelineCacheCreateFlagBits` specifying the behavior of the pipeline cache.
- **initialDataSize** is the number of bytes in `pInitialData`. If `initialDataSize` is zero, the pipeline cache will initially be empty.
- **pInitialData** is a pointer to previously retrieved pipeline cache data. If the pipeline cache data is incompatible (as defined below) with the device, the pipeline cache will be initially empty. If `initialDataSize` is zero, `pInitialData` is ignored.

Valid Usage

- If `initialDataSize` is not 0, it **must** be equal to the size of `pInitialData`, as returned by `vkGetPipelineCacheData` when `pInitialData` was originally retrieved.
- If `initialDataSize` is not 0, `pInitialData` **must** have been retrieved from a previous call to `vkGetPipelineCacheData`.
- If the `pipelineCreationCacheControl` feature is not enabled, **flags** **must** not include `VK_PIPELINE_CACHE_CREATE_EXTERNALLY_SYNCHRONIZED_BIT_EXT`
Valid Usage (Implicit)

• `sType` **must** be `VK_STRUCTURE_TYPE_PIPELINE_CACHE_CREATE_INFO`
• `pNext` **must** be `NULL`
• `flags` **must** be a valid combination of `VkPipelineCacheCreateFlagBits` values
• If `initialDataSize` is not 0, `pInitialData` **must** be a valid pointer to an array of `initialDataSize` bytes

```c
typedef VkFlags VkPipelineCacheCreateFlags;
```

`VkPipelineCacheCreateFlags` is a bitmask type for setting a mask of zero or more `VkPipelineCacheCreateFlagBits`.

Possible values of the `flags` member of `VkPipelineCacheCreateInfo`, specifying the behavior of the pipeline cache, are:

```c
typedef enum VkPipelineCacheCreateFlagBits {
    VK_PIPELINE_CACHE_CREATE_EXTERNALLY_SYNCHRONIZED_BIT_EXT = 0x00000001,
} VkPipelineCacheCreateFlagBits;
```

• `VK_PIPELINE_CACHE_CREATE_EXTERNALLY_SYNCHRONIZED_BIT_EXT` specifies that all commands that modify the created `VkPipelineCache` will be *externally synchronized*. When set, the implementation may skip any unnecessary processing needed to support simultaneous modification from multiple threads where allowed.

Pipeline cache objects can be merged using the command:

```c
VkResult vkMergePipelineCaches(
    VkDevice device,              /* device, */
    VkPipelineCache dstCache,     /* dstCache, */
    uint32_t srcCacheCount,        /* srcCacheCount, */
    const VkPipelineCache* pSrcCaches); /* pSrcCaches */
```

• `device` is the logical device that owns the pipeline cache objects.
• `dstCache` is the handle of the pipeline cache to merge results into.
• `srcCacheCount` is the length of the `pSrcCaches` array.
• `pSrcCaches` is a pointer to an array of pipeline cache handles, which will be merged into `dstCache`. The previous contents of `dstCache` are included after the merge.
Note
The details of the merge operation are implementation dependent, but implementations **should** merge the contents of the specified pipelines and prune duplicate entries.

Valid Usage
• **dstCache** must not appear in the list of source caches

Valid Usage (Implicit)
• **device** must be a valid `VkDevice` handle
• **dstCache** must be a valid `VkPipelineCache` handle
• **pSrcCaches** must be a valid pointer to an array of **srcCacheCount** valid `VkPipelineCache` handles
• **srcCacheCount** must be greater than 0
• **dstCache** must have been created, allocated, or retrieved from **device**
• Each element of **pSrcCaches** must have been created, allocated, or retrieved from **device**

Host Synchronization
• Host access to **dstCache** must be externally synchronized

Return Codes
**Success**
• **VK_SUCCESS**

**Failure**
• **VK_ERROR_OUT_OF_HOST_MEMORY**
• **VK_ERROR_OUT_OF_DEVICE_MEMORY**

Data can be retrieved from a pipeline cache object using the command:

```c
VkResult vkGetPipelineCacheData(
    VkDevice                                    device,
    VkPipelineCache                             pipelineCache,
    size_t*                                     pDataSize,
    void*                                       pData);
```
• **device** is the logical device that owns the pipeline cache.

• **pipelineCache** is the pipeline cache to retrieve data from.

• **pDataSize** is a pointer to a `size_t` value related to the amount of data in the pipeline cache, as described below.

• **pData** is either `NULL` or a pointer to a buffer.

If **pData** is `NULL`, then the maximum size of the data that can be retrieved from the pipeline cache, in bytes, is returned in **pDataSize**. Otherwise, **pDataSize** must point to a variable set by the user to the size of the buffer, in bytes, pointed to by **pData**, and on return the variable is overwritten with the amount of data actually written to **pData**.

If **pDataSize** is less than the maximum size that can be retrieved by the pipeline cache, at most **pDataSize** bytes will be written to **pData**, and **vkGetPipelineCacheData** will return `VK_INCOMPLETE`. Any data written to **pData** is valid and can be provided as the **pInitialData** member of the **VkPipelineCacheCreateInfo** structure passed to **vkCreatePipelineCache**.

Two calls to **vkGetPipelineCacheData** with the same parameters must retrieve the same data unless a command that modifies the contents of the cache is called between them.

Applications can store the data retrieved from the pipeline cache, and use these data, possibly in a future run of the application, to populate new pipeline cache objects. The results of pipeline compiles, however, may depend on the vendor ID, device ID, driver version, and other details of the device. To enable applications to detect when previously retrieved data is incompatible with the device, the initial bytes written to **pData** must be a header consisting of the following members:

### Table 12. Layout for pipeline cache header version `VK_PIPELINE_CACHE_HEADER_VERSION_ONE`

<table>
<thead>
<tr>
<th>Offset</th>
<th>Size</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>length in bytes of the entire pipeline cache header written as a stream of bytes, with the least significant byte first</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>a <strong>VkPipelineCacheHeaderVersion</strong> value written as a stream of bytes, with the least significant byte first</td>
</tr>
<tr>
<td>8</td>
<td>4</td>
<td>a vendor ID equal to <strong>VkPhysicalDeviceProperties</strong>::<strong>vendorID</strong> written as a stream of bytes, with the least significant byte first</td>
</tr>
<tr>
<td>12</td>
<td>4</td>
<td>a device ID equal to <strong>VkPhysicalDeviceProperties</strong>::<strong>deviceID</strong> written as a stream of bytes, with the least significant byte first</td>
</tr>
<tr>
<td>16</td>
<td><code>VK_UUID_SIZE</code></td>
<td>a pipeline cache ID equal to <strong>VkPhysicalDeviceProperties</strong>::<strong>pipelineCacheUUID</strong></td>
</tr>
</tbody>
</table>

The first four bytes encode the length of the entire pipeline cache header, in bytes. This value includes all fields in the header including the pipeline cache version field and the size of the length field.

The next four bytes encode the pipeline cache version, as described for...
A consumer of the pipeline cache **should** use the cache version to interpret the remainder of the cache header.

If `pDataSize` is less than what is necessary to store this header, nothing will be written to `pData` and zero will be written to `pDataSize`.

**Valid Usage (Implicit)**

- `device` **must** be a valid `VkDevice` handle
- `pipelineCache` **must** be a valid `VkPipelineCache` handle
- `pDataSize` **must** be a valid pointer to a `size_t` value
- If the value referenced by `pDataSize` is not 0, and `pData` is not `NULL`, `pData` **must** be a valid pointer to an array of `pDataSize` bytes
- `pipelineCache` **must** have been created, allocated, or retrieved from `device`

**Return Codes**

**Success**

- `VK_SUCCESS`
- `VK_INCOMPLETE`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OFDEVICE_MEMORY`

Possible values of the second group of four bytes in the header returned by `vkGetPipelineCacheData`, encoding the pipeline cache version, are:

```c
typedef enum VkPipelineCacheHeaderVersion {
  VK_PIPELINE_CACHE_HEADER_VERSION_ONE = 1,
} VkPipelineCacheHeaderVersion;
```

- `VK_PIPELINE_CACHE_HEADER_VERSION_ONE` specifies version one of the pipeline cache.

To destroy a pipeline cache, call:

```c
void vkDestroyPipelineCache(  
  VkDevice device,  
  VkPipelineCache pipelineCache,  
  const VkAllocationCallbacks* pAllocator);
```

- `device` is the logical device that destroys the pipeline cache object.
- `pipelineCache` is the handle of the pipeline cache to destroy.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

### Valid Usage

- If `VkAllocationCallbacks` were provided when `pipelineCache` was created, a compatible set of callbacks **must** be provided here.
- If no `VkAllocationCallbacks` were provided when `pipelineCache` was created, `pAllocator` **must** be `NULL`.

### Valid Usage (Implicit)

- `device` **must** be a valid `VkDevice` handle.
- If `pipelineCache` is not `VK_NULL_HANDLE`, `pipelineCache` **must** be a valid `VkPipelineCache` handle.
- If `pAllocator` is not `NULL`, `pAllocator` **must** be a valid pointer to a valid `VkAllocationCallbacks` structure.
- If `pipelineCache` is a valid handle, it **must** have been created, allocated, or retrieved from `device`.

### Host Synchronization

- Host access to `pipelineCache` **must** be externally synchronized.

## 9.7. Specialization Constants

Specialization constants are a mechanism whereby constants in a SPIR-V module **can** have their constant value specified at the time the `VkPipeline` is created. This allows a SPIR-V module to have constants that **can** be modified while executing an application that uses the Vulkan API.

**Note**

Specialization constants are useful to allow a compute shader to have its local workgroup size changed at runtime by the user, for example.

Each `VkPipelineShaderStageCreateInfo` structure contains a `pSpecializationInfo` member, which **can** be `NULL` to indicate no specialization constants, or point to a `VkSpecializationInfo` structure.

The `VkSpecializationInfo` structure is defined as:
typedef struct VkSpecializationInfo {
    uint32_t mapEntryCount;
    const VkSpecializationMapEntry* pMapEntries;
    size_t dataSize;
    const void* pData;
} VkSpecializationInfo;

- **mapEntryCount** is the number of entries in the **pMapEntries** array.
- **pMapEntries** is a pointer to an array of **VkSpecializationMapEntry** structures which map constant IDs to offsets in **pData**.
- **dataSize** is the byte size of the **pData** buffer.
- **pData** contains the actual constant values to specialize with.

**pMapEntries** is a pointer to a **VkSpecializationMapEntry** structure.

### Valid Usage

- The **offset** member of each element of **pMapEntries** must be less than **dataSize**
- The **size** member of each element of **pMapEntries** must be less than or equal to **dataSize** minus **offset**

### Valid Usage (Implicit)

- If **mapEntryCount** is not 0, **pMapEntries** must be a valid pointer to an array of **mapEntryCount** valid **VkSpecializationMapEntry** structures
- If **dataSize** is not 0, **pData** must be a valid pointer to an array of **dataSize** bytes

The **VkSpecializationMapEntry** structure is defined as:

typedef struct VkSpecializationMapEntry {
    uint32_t constantID;
    uint32_t offset;
    size_t size;
} VkSpecializationMapEntry;

- **constantID** is the ID of the specialization constant in SPIR-V.
- **offset** is the byte offset of the specialization constant value within the supplied data buffer.
- **size** is the byte size of the specialization constant value within the supplied data buffer.

If a **constantID** value is not a specialization constant ID used in the shader, that map entry does not affect the behavior of the pipeline.
Valid Usage

- For a `constantID` specialization constant declared in a shader, `size` must match the byte size of the `constantID`. If the specialization constant is of type `boolean`, `size` must be the byte size of `VkBool32`.

In human readable SPIR-V:

```spirv
OpDecorate %x SpecId 13 ; decorate .x component of WorkgroupSize with ID 13
OpDecorate %y SpecId 42 ; decorate .y component of WorkgroupSize with ID 42
OpDecorate %z SpecId 3 ; decorate .z component of WorkgroupSize with ID 3
OpDecorate %wgsize BuiltIn WorkgroupSize ; decorate WorkgroupSize onto constant
%i32 = OpTypeInt 32 0 ; declare an unsigned 32-bit type
%uvec3 = OpTypeVector %i32 3 ; declare a 3 element vector type of unsigned 32-bit
%x = OpSpecConstant %i32 1 ; declare the .x component of WorkgroupSize
%y = OpSpecConstant %i32 1 ; declare the .y component of WorkgroupSize
%z = OpSpecConstant %i32 1 ; declare the .z component of WorkgroupSize
%wgsize = OpSpecConstantComposite %uvec3 %x %y %z ; declare WorkgroupSize
```

From the above we have three specialization constants, one for each of the x, y & z elements of the `WorkgroupSize` vector.

Now to specialize the above via the specialization constants mechanism:
const VkSpecializationMapEntry entries[] = {
    {13, 0 * sizeof(uint32_t), sizeof(uint32_t)},
    {42, 1 * sizeof(uint32_t), sizeof(uint32_t)},
    {3, 2 * sizeof(uint32_t), sizeof(uint32_t)}
};

const uint32_t data[] = {16, 8, 4}; // our workgroup size is 16x8x4

const VkSpecializationInfo info = {
    3, // mapEntryCount
    entries, // pMapEntries
    3 * sizeof(uint32_t), // dataSize
    data, // pData
};

Then when calling vkCreateComputePipelines, and passing the VkSpecializationInfo we defined as the pSpecializationInfo parameter of VkPipelineShaderStageCreateInfo, we will create a compute pipeline with the runtime specified local workgroup size.

Another example would be that an application has a SPIR-V module that has some platform-dependent constants they wish to use.

In human readable SPIR-V:

OpDecorate %1 SpecId 0 ; decorate our signed 32-bit integer constant
OpDecorate %2 SpecId 12 ; decorate our 32-bit floating-point constant
%i32 = OpTypeInt 32 1 ; declare a signed 32-bit type
%float = OpTypeFloat 32 ; declare a 32-bit floating-point type
%1 = OpSpecConstant %i32 -1 ; some signed 32-bit integer constant
%2 = OpSpecConstant %float 0.5 ; some 32-bit floating-point constant

From the above we have two specialization constants, one is a signed 32-bit integer and the second is a 32-bit floating-point.
Now to specialize the above via the specialization constants mechanism:

```c
struct SpecializationData {
    int32_t data0;
    float data1;
};

const VkSpecializationMapEntry entries[] = {
    { 0, offsetof(SpecializationData, data0), sizeof(SpecializationData::data0) },
    { 12, offsetof(SpecializationData, data1), sizeof(SpecializationData::data1) }
};

SpecializationData data;
data.data0 = -42; // set the data for the 32-bit integer
data.data1 = 42.0f; // set the data for the 32-bit floating-point

const VkSpecializationInfo info = {
    2, // mapEntryCount
    entries, // pMapEntries
    sizeof(data), // dataSize
    &data, // pData
};
```

It is legal for a SPIR-V module with specializations to be compiled into a pipeline where no specialization info was provided. SPIR-V specialization constants contain default values such that if a specialization is not provided, the default value will be used. In the examples above, it would be valid for an application to only specialize some of the specialization constants within the SPIR-V module, and let the other constants use their default values encoded within the OpSpecConstant declarations.

## 9.8. Pipeline Libraries

A pipeline library is a special pipeline that was created using the `VK_PIPELINE_CREATE_LIBRARY_BIT_KHR` and cannot be bound, instead it defines a set of pipeline state which can be linked into other pipelines. For ray tracing pipelines this includes shaders and shader groups. The application must maintain the lifetime of pipeline libraries based on the pipelines that link with it. A pipeline library is considered in-use, as long as one of the linking pipelines is in-use.

This linkage is achieved by using the following structure within the appropriate creation
mechanisms:

The `VkPipelineLibraryCreateInfoKHR` structure is defined as:

```c
typedef struct VkPipelineLibraryCreateInfoKHR {
    VkStructureType      sType;
    const void*          pNext;
    uint32_t             libraryCount;
    const VkPipeline*    pLibraries;
} VkPipelineLibraryCreateInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `libraryCount` is the number of pipeline libraries in `pLibraries`.
- `pLibraries` is an array of pipeline libraries to use when creating a pipeline.

**Valid Usage**

- Each element of `pLibraries` must have been created with `VK_PIPELINE_CREATE_LIBRARY_BIT_KHR`.

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_PIPELINE_LIBRARY_CREATE_INFO_KHR`.
- `pNext` must be `NULL`.
- If `libraryCount` is not `0`, `pLibraries` must be a valid pointer to an array of `libraryCount` valid `VkPipeline` handles.

### 9.9. Pipeline Binding

Once a pipeline has been created, it **can** be bound to the command buffer using the command:

```c
void vkCmdBindPipeline(
    VkCommandBuffer   commandBuffer,
    VkPipelineBindPoint pipelineBindPoint,
    VkPipeline        pipeline);
```

- `commandBuffer` is the command buffer that the pipeline will be bound to.
- `pipelineBindPoint` is a `VkPipelineBindPoint` value specifying whether to bind to the compute or graphics bind point. Binding one does not disturb the other.
- `pipeline` is the pipeline to be bound.
Once bound, a pipeline binding affects subsequent graphics or compute commands in the command buffer until a different pipeline is bound to the bind point. The pipeline bound to \texttt{VK_PIPELINE_BIND_POINT_COMPUTE} controls the behavior of \texttt{vkCmdDispatch} and \texttt{vkCmdDispatchIndirect}. The pipeline bound to \texttt{VK_PIPELINE_BIND_POINT_GRAPHICS} controls the behavior of all drawing commands. The pipeline bound to \texttt{VK_PIPELINE_BIND_POINT_RAY_TRACING_KHR} controls the behavior of \texttt{vkCmdTraceRaysKHR}. No other commands are affected by the pipeline state.

### Valid Usage

- If \texttt{pipelineBindPoint} is \texttt{VK_PIPELINE_BIND_POINT_COMPUTE}, the \texttt{VkCommandPool} that \texttt{commandBuffer} was allocated from must support compute operations.

- If \texttt{pipelineBindPoint} is \texttt{VK_PIPELINE_BIND_POINT_GRAPHICS}, the \texttt{VkCommandPool} that \texttt{commandBuffer} was allocated from must support graphics operations.

- If \texttt{pipelineBindPoint} is \texttt{VK_PIPELINE_BIND_POINT_COMPUTE}, pipeline must be a compute pipeline.

- If \texttt{pipelineBindPoint} is \texttt{VK_PIPELINE_BIND_POINT_GRAPHICS}, pipeline must be a graphics pipeline.

- If the variable multisample rate feature is not supported, pipeline is a graphics pipeline, the current subpass uses no attachments, and this is not the first call to this function with a graphics pipeline after transitioning to the current subpass, then the sample count specified by this pipeline must match that set in the previous pipeline.

- If \texttt{VkPhysicalDeviceSampleLocationsPropertiesEXT::variableSampleLocations} is \texttt{VK_FALSE}, and pipeline is a graphics pipeline created with a \texttt{VkPipelineSampleLocationsStateCreateInfoEXT} structure having its \texttt{sampleLocationsEnable} member set to \texttt{VK_TRUE} but without \texttt{VK_DYNAMIC_STATE_SAMPLE_LOCATIONS_EXT} enabled then the current render pass instance must have been begun by specifying a \texttt{VkRenderPassSampleLocationsBeginInfoEXT} structure whose \texttt{pPostSubpassSampleLocations} member contains an element with a \texttt{subpassIndex} matching the current subpass index and the \texttt{sampleLocationsInfo} member of that element must match the \texttt{sampleLocationsInfo} specified in \texttt{VkPipelineSampleLocationsStateCreateInfoEXT} when the pipeline was created.

- This command must not be recorded when transform feedback is active.

- If \texttt{pipelineBindPoint} is \texttt{VK_PIPELINE_BIND_POINT_RAY_TRACING_KHR}, the \texttt{VkCommandPool} that \texttt{commandBuffer} was allocated from must support compute operations.

- If \texttt{pipelineBindPoint} is \texttt{VK_PIPELINE_BIND_POINT_RAY_TRACING_KHR}, the pipeline must be a ray tracing pipeline.

- The pipeline must not have been created with \texttt{VK_PIPELINE_CREATE_LIBRARY_BIT_KHR} set.
Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `pipelineBindPoint` must be a valid `VkPipelineBindPoint` value
- `pipeline` must be a valid `VkPipeline` handle
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics, or compute operations
- Both of `commandBuffer`, and `pipeline` must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Both</td>
<td>Graphics</td>
<td>Graphics</td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td>Compute</td>
<td>Compute</td>
</tr>
</tbody>
</table>

Possible values of `vkCmdBindPipeline::pipelineBindPoint`, specifying the bind point of a pipeline object, are:

```cpp
typedef enum VkPipelineBindPoint {
    VK_PIPELINE_BIND_POINT_GRAPHICS = 0,
    VK_PIPELINE_BIND_POINT_COMPUTE = 1,
    VK_PIPELINE_BIND_POINT_RAY_TRACING_KHR = 1000165000,
    VK_PIPELINE_BIND_POINT_RAY_TRACING_NV = VK_PIPELINE_BIND_POINT_RAY_TRACING_KHR,
} VkPipelineBindPoint;
```

- `VK_PIPELINE_BIND_POINT_COMPUTE` specifies binding as a compute pipeline.
- `VK_PIPELINE_BIND_POINT_GRAPHICS` specifies binding as a graphics pipeline.
- `VK_PIPELINE_BIND_POINT_RAY_TRACING_KHR` specifies binding as a ray tracing pipeline.

For pipelines that were created with the support of multiple shader groups (see Graphics Pipeline Shader Groups), the regular `vkCmdBindPipeline` command will bind Shader Group 0. To explicitly
void vkCmdBindPipelineShaderGroupNV(
    VkCommandBuffer commandBuffer,
    VkPipelineBindPoint pipelineBindPoint,
    VkPipeline pipeline,
    uint32_t groupIndex);

- `commandBuffer` is the command buffer that the pipeline will be bound to.
- `pipelineBindPoint` is a `VkPipelineBindPoint` value specifying to which bind point the pipeline is bound.
- `pipeline` is the pipeline to be bound.
- `groupIndex` is the shader group to be bound.

### Valid Usage

- `groupIndex` must be 0 or less than the effective `VkGraphicsPipelineShaderGroupsCreateInfoNV::groupCount` including the referenced pipelines.
- The `pipelineBindPoint` must be `VK_PIPELINE_BIND_POINT_GRAPHICS`.
- The same restrictions as `vkCmdBindPipeline` apply as if the bound pipeline was created only with the Shader Group from the `groupIndex` information.
- The `VkPhysicalDeviceDeviceGeneratedCommandsFeaturesNV::deviceGeneratedCommands` feature must be enabled.

### Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle.
- `pipelineBindPoint` must be a valid `VkPipelineBindPoint` value.
- `pipeline` must be a valid `VkPipeline` handle.
- `commandBuffer` must be in the recording state.
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics, or compute operations.
- Both of `commandBuffer`, and `pipeline` must have been created, allocated, or retrieved from the same `VkDevice`.

bind a shader group use:
Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>

</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Both</td>
<td>Graphics</td>
<td>Compute</td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

9.10. Dynamic State

When a pipeline object is bound, any pipeline object state that is not specified as dynamic is applied to the command buffer state. Pipeline object state that is specified as dynamic is not applied to the command buffer state at this time. Instead, dynamic state can be modified at any time and persists for the lifetime of the command buffer, or until modified by another dynamic state setting command or another pipeline bind.

When a pipeline object is bound, the following applies to each state parameter:

- If the state is not specified as dynamic in the new pipeline object, then that command buffer state is overwritten by the state in the new pipeline object. Before any draw or dispatch call with this pipeline there must not have been any call to any of the corresponding dynamic state setting commands after this pipeline was bound.
- If the state is specified as dynamic in the new pipeline object, then that command buffer state is not disturbed. Before any draw or dispatch call with this pipeline there must have been at least one call to each of the corresponding dynamic state setting commands since the command buffer recording was begun, or the last bound pipeline object with that state specified as static, whichever was the latter.

Dynamic state that does not affect the result of operations can be left undefined.

Note

For example, if blending is disabled by the pipeline object state then the dynamic color blend constants do not need to be specified in the command buffer, even if this state is specified as dynamic in the pipeline object.

9.11. Pipeline Shader Information

When a pipeline is created, its state and shaders are compiled into zero or more device-specific
executables, which are used when executing commands against that pipeline. To query the properties of these executables, call:

```c
VkResult vkGetPipelineExecutablePropertiesKHR(
    VkDevice device,
    const VkPipelineInfoKHR* pPipelineInfo,
    uint32_t* pExecutableCount,
    VkPipelineExecutablePropertiesKHR* pProperties);
```

- **device** is the device that created the pipeline.
- **pPipelineInfo** describes the pipeline being queried.
- **pExecutableCount** is a pointer to an integer related to the number of pipeline executables available or queried, as described below.
- **pProperties** is either **NULL** or a pointer to an array of **VkPipelineExecutablePropertiesKHR** structures.

If **pProperties** is **NULL**, then the number of executables associated with the pipeline is returned in **pExecutableCount**. Otherwise, **pExecutableCount** must point to a variable set by the user to the number of elements in the **pProperties** array, and on return the variable is overwritten with the number of structures actually written to **pProperties**. If **pExecutableCount** is less than the number of executables associated with the pipeline, at most **pExecutableCount** structures will be written and **vkGetPipelineExecutablePropertiesKHR** will return **VK_INCOMPLETE**.

### Valid Usage

- **pipelineExecutableInfo** must be enabled
- **pipeline** member of **pPipelineInfo** must have been created with **device**

### Valid Usage (Implicit)

- **device** must be a valid **VkDevice** handle
- **pPipelineInfo** must be a valid pointer to a valid **VkPipelineInfoKHR** structure
- **pExecutableCount** must be a valid pointer to a **uint32_t** value
- If the value referenced by **pExecutableCount** is not 0, and **pProperties** is not **NULL**, **pProperties** must be a valid pointer to an array of **pExecutableCount** **VkPipelineExecutablePropertiesKHR** structures
Return Codes

Success
- VK_SUCCESS
- VK_INCOMPLETE

Failure
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

The `VkPipelineInfoKHR` structure is defined as:

```c
typedef struct VkPipelineInfoKHR {
    VkStructureType    sType;
    const void*        pNext;
    VkPipeline         pipeline;
} VkPipelineInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `pipeline` is a `VkPipeline` handle.

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_PIPELINE_INFO_KHR`
- `pNext` must be `NULL`
- `pipeline` must be a valid `VkPipeline` handle

The `VkPipelineExecutablePropertiesKHR` structure is defined as:

```c
typedef struct VkPipelineExecutablePropertiesKHR {
    VkStructureType       sType;
    void*                 pNext;
    VkShaderStageFlags    stages;
    char                   name[VK_MAX_DESCRIPTION_SIZE];
    char                   description[VK_MAX_DESCRIPTION_SIZE];
    uint32_t              subgroupSize;
} VkPipelineExecutablePropertiesKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
• **stages** is a bitmask of `VkShaderStageFlagBits` indicating which shader stages (if any) were principally used as inputs to compile this pipeline executable.

• **name** is an array of `VK_MAX_DESCRIPTION_SIZE char` containing a null-terminated UTF-8 string which is a short human readable name for this executable.

• **description** is an array of `VK_MAX_DESCRIPTION_SIZE char` containing a null-terminated UTF-8 string which is a human readable description for this executable.

• **subgroupSize** is the subgroup size with which this executable is dispatched.

The **stages** field **may** be zero or it **may** contain one or more bits describing the stages principally used to compile this pipeline. Not all implementations have a 1:1 mapping between shader stages and pipeline executables and some implementations **may** reduce a given shader stage to fixed function hardware programming such that no executable is available. No guarantees are provided about the mapping between shader stages and pipeline executables and **stages should** be considered a best effort hint. Because the application **cannot** rely on the **stages** field to provide an exact description, **name** and **description** provide a human readable name and description which more accurately describes the given pipeline executable.

**Valid Usage (Implicit)**

- **sType** **must** be `VK_STRUCTURE_TYPE_PIPELINE_EXECUTABLE_PROPERTIES_KHR`
- **pNext** **must** be `NULL`

Each pipeline executable **may** have a set of statistics associated with it that are generated by the pipeline compilation process. These statistics **may** include things such as instruction counts, amount of spilling (if any), maximum number of simultaneous threads, or anything else which **may** aid developers in evaluating the expected performance of a shader. To query the compile-time statistics associated with a pipeline executable, call:

```c
VkResult vkGetPipelineExecutableStatisticsKHR(
    VkDevice device,
    const VkPipelineExecutableInfoKHR* pExecutableInfo,
    uint32_t* pStatisticCount,
    VkPipelineExecutableStatisticKHR* pStatistics);
```

- **device** is the device that created the pipeline.
- **pExecutableInfo** describes the pipeline executable being queried.
- **pStatisticCount** is a pointer to an integer related to the number of statistics available or queried, as described below.
- **pStatistics** is either `NULL` or a pointer to an array of `VkPipelineExecutableStatisticKHR` structures.

If **pStatistics** is `NULL`, then the number of statistics associated with the pipeline executable is returned in **pStatisticCount**. Otherwise, **pStatisticCount** **must** point to a variable set by the user to the number of elements in the **pStatistics** array, and on return the variable is overwritten with the
number of structures actually written to `pStatistics`. If `pStatisticCount` is less than the number of statistics associated with the pipeline executable, at most `pStatisticCount` structures will be written and `vkGetPipelineExecutableStatisticsKHR` will return `VK_INCOMPLETE`.

### Valid Usage

- `pipelineExecutableInfo` must be enabled
- `pipeline` member of `pExecutableInfo` must have been created with `device`
- `pipeline` member of `pExecutableInfo` must have been created with `VK_PIPELINE_CREATE_CAPTURE_STATISTICS_BIT_KHR` set in the `flags` field of `VkGraphicsPipelineCreateInfo` or `VkComputePipelineCreateInfo`

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pExecutableInfo` must be a valid pointer to a valid `VkPipelineExecutableInfoKHR` structure
- `pStatisticCount` must be a valid pointer to a `uint32_t` value
- If the value referenced by `pStatisticCount` is not 0, and `pStatistics` is not NULL, `pStatistics` must be a valid pointer to an array of `pStatisticCount` `VkPipelineExecutableStatisticKHR` structures

### Return Codes

**Success**

- `VK_SUCCESS`
- `VK_INCOMPLETE`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

The `VkPipelineExecutableInfoKHR` structure is defined as:

```c
typedef struct VkPipelineExecutableInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkPipeline pipeline;
    uint32_t executableIndex;
} VkPipelineExecutableInfoKHR;
```
- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **pipeline** is the pipeline to query.
- **executableIndex** is the index of the executable to query in the array of executable properties returned by `vkGetPipelineExecutablePropertiesKHR`.

### Valid Usage

- **executableIndex** must be less than the number of executables associated with **pipeline** as returned in the **pExecutableCount** parameter of `vkGetPipelineExecutablePropertiesKHR`.

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_PIPELINE_EXECUTABLE_INFO_KHR`.
- **pNext** must be NULL.
- **pipeline** must be a valid `VkPipeline` handle.

The `VkPipelineExecutableStatisticKHR` structure is defined as:

```c
typedef struct VkPipelineExecutableStatisticKHR {
    VkStructureType                           sType;
    void*                                     pNext;
    char name[VK_MAX_DESCRIPTION_SIZE];
    char description[VK_MAX_DESCRIPTION_SIZE];
    VkPipelineExecutableStatisticFormatKHR    format;
    VkPipelineExecutableStatisticValueKHR     value;
} VkPipelineExecutableStatisticKHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **name** is an array of `VK_MAX_DESCRIPTION_SIZE` char containing a null-terminated UTF-8 string which is a short human readable name for this statistic.
- **description** is an array of `VK_MAX_DESCRIPTION_SIZE` char containing a null-terminated UTF-8 string which is a human readable description for this statistic.
- **format** is a `VkPipelineExecutableStatisticFormatKHR` value specifying the format of the data found in **value**.
- **value** is the value of this statistic.
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_PIPELINE_EXECUTABLE_STATISTIC_KHR`
- `pNext` must be `NULL`

The `VkPipelineExecutableStatisticFormatKHR` enum is defined as:

```c
typedef enum VkPipelineExecutableStatisticFormatKHR {
    VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_BOOL32_KHR = 0,
    VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_INT64_KHR = 1,
    VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_UINT64_KHR = 2,
    VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_FLOAT64_KHR = 3,
} VkPipelineExecutableStatisticFormatKHR;
```

- `VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_BOOL32_KHR` specifies that the statistic is returned as a 32-bit boolean value which `must` be either `VK_TRUE` or `VK_FALSE` and `should` be read from the `b32` field of `VkPipelineExecutableStatisticValueKHR`.

- `VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_INT64_KHR` specifies that the statistic is returned as a signed 64-bit integer and `should` be read from the `i64` field of `VkPipelineExecutableStatisticValueKHR`.

- `VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_UINT64_KHR` specifies that the statistic is returned as an unsigned 64-bit integer and `should` be read from the `u64` field of `VkPipelineExecutableStatisticValueKHR`.

- `VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_FLOAT64_KHR` specifies that the statistic is returned as a 64-bit floating-point value and `should` be read from the `f64` field of `VkPipelineExecutableStatisticValueKHR`.

The `VkPipelineExecutableStatisticValueKHR` union is defined as:

```c
typedef union VkPipelineExecutableStatisticValueKHR {
    VkBool32    b32;
    int64_t     i64;
    uint64_t    u64;
    double     f64;
} VkPipelineExecutableStatisticValueKHR;
```

- `b32` is the 32-bit boolean value if the `VkPipelineExecutableStatisticFormatKHR` is `VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_BOOL32_KHR`.

- `i64` is the signed 64-bit integer value if the `VkPipelineExecutableStatisticFormatKHR` is `VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_INT64_KHR`.

- `u64` is the unsigned 64-bit integer value if the `VkPipelineExecutableStatisticFormatKHR` is `VK_PIPELINE_EXECUTABLE_STATISTIC_FORMAT_UINT64_KHR`.

- `f64` is the 64-bit floating-point value if the `VkPipelineExecutableStatisticFormatKHR` is
Each pipeline executable may have one or more text or binary internal representations associated with it which are generated as part of the compile process. These may include the final shader assembly, a binary form of the compiled shader, or the shader compiler’s internal representation at any number of intermediate compile steps. To query the internal representations associated with a pipeline executable, call:

```c
VkResult vkGetPipelineExecutableInternalRepresentationsKHR(
    VkDevice device,
    const VkPipelineExecutableInfoKHR* pExecutableInfo,
    uint32_t* pInternalRepresentationCount,
    VkPipelineExecutableInternalRepresentationKHR* pInternalRepresentations);
```

- `device` is the device that created the pipeline.
- `pExecutableInfo` describes the pipeline executable being queried.
- `pInternalRepresentationCount` is a pointer to an integer related to the number of internal representations available or queried, as described below.
- `pInternalRepresentations` is either `NULL` or a pointer to an array of `VkPipelineExecutableInternalRepresentationKHR` structures.

If `pInternalRepresentations` is `NULL`, then the number of internal representations associated with the pipeline executable is returned in `pInternalRepresentationCount`. Otherwise, `pInternalRepresentationCount` must point to a variable set by the user to the number of elements in the `pInternalRepresentations` array, and on return the variable is overwritten with the number of structures actually written to `pInternalRepresentations`. If `pInternalRepresentationCount` is less than the number of internal representations associated with the pipeline executable, at most `pInternalRepresentationCount` structures will be written and `vkGetPipelineExecutableInternalRepresentationsKHR` will return `VK_INCOMPLETE`.

While the details of the internal representations remain implementation dependent, the implementation should order the internal representations in the order in which they occur in the compile pipeline with the final shader assembly (if any) last.

**Valid Usage**

- `pipelineExecutableInfo` must be enabled
- `pipeline` member of `pExecutableInfo` must have been created with `device`
- `pipeline` member of `pExecutableInfo` must have been created with `VK_PIPELINE_CREATE_CAPTURE_INTERNAL_REPRESENTATIONS_BIT_KHR` set in the `flags` field of `VkGraphicsPipelineCreateInfo` or `VkComputePipelineCreateInfo`
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pExecutableInfo** must be a valid pointer to a valid `VkPipelineExecutableInfoKHR` structure
- **pInternalRepresentationCount** must be a valid pointer to a `uint32_t` value
- If the value referenced by **pInternalRepresentationCount** is not 0, and **pInternalRepresentations** is not `NULL`, **pInternalRepresentations** must be a valid pointer to an array of `VkPipelineExecutableInternalRepresentationKHR` structures

Return Codes

**Success**

- **VK_SUCCESS**
- **VK_INCOMPLETE**

**Failure**

- **VK_ERROR_OUT_OF_HOST_MEMORY**
- **VK_ERROR_OUT_OF_DEVICE_MEMORY**

The `VkPipelineExecutableInternalRepresentationKHR` structure is defined as:

```c
typedef struct VkPipelineExecutableInternalRepresentationKHR {
  VkStructureType sType;
  void* pNext;
  char name[VK_MAX_DESCRIPTION_SIZE];
  char description[VK_MAX_DESCRIPTION_SIZE];
  VkBool32 isText;
  size_t dataSize;
  void* pData;
} VkPipelineExecutableInternalRepresentationKHR;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **name** is an array of `VK_MAX_DESCRIPTION_SIZE` `char` containing a null-terminated UTF-8 string which is a short human readable name for this internal representation.
- **description** is an array of `VK_MAX_DESCRIPTION_SIZE` `char` containing a null-terminated UTF-8 string which is a human readable description for this internal representation.
- **isText** specifies whether the returned data is text or opaque data. If **isText** is **VK_TRUE** then the data returned in **pData** is text and is guaranteed to be a null-terminated UTF-8 string.
• **dataSize** is an integer related to the size, in bytes, of the internal representation data, as described below.

• **pData** is either **NULL** or a pointer to an block of data into which the implementation will write the textual form of the internal representation.

If **pData** is **NULL**, then the size, in bytes, of the internal representation data is returned in **dataSize**. Otherwise, **dataSize** must be the size of the buffer, in bytes, pointed to by **pData** and on return **dataSize** is overwritten with the number of bytes of data actually written to **pData** including any trailing null character. If **dataSize** is less than the size, in bytes, of the internal representation data, at most **dataSize** bytes of data will be written to **pData** and **vkGetPipelineExecutableInternalRepresentationsKHR** will return **VK_INCOMPLETE**. If **isText** is **VK_TRUE** and **pData** is not **NULL** and **dataSize** is not zero, the last byte written to **pData** will be a null character.

---

**Valid Usage (Implicit)**

• **sType** must be **VK_STRUCTURE_TYPE_PIPELINE_EXECUTABLE_INTERNAL_REPRESENTATION_KHR**

• **pNext** must be **NULL**

Information about a particular shader that has been compiled as part of a pipeline object can be extracted by calling:

```c
VkResult vkGetShaderInfoAMD(
    VkDevice device,                  // device that created pipeline
    VkPipeline pipeline,              // target of the query
    VkShaderStageFlagBits shaderStage, // identifies the particular shader within the pipeline about which information is being queried
    VkShaderInfoTypeAMD infoType,     // describes what kind of information is being queried
    size_t* pInfoSize,                // a pointer to a value related to the amount of data the query returns, as described below
    void* pInfo);                     // a pointer to a buffer
```

• **device** is the device that created **pipeline**.

• **pipeline** is the target of the query.

• **shaderStage** identifies the particular shader within the pipeline about which information is being queried.

• **infoType** describes what kind of information is being queried.

• **pInfoSize** is a pointer to a value related to the amount of data the query returns, as described below.

• **pInfo** is either **NULL** or a pointer to a buffer.

If **pInfo** is **NULL**, then the maximum size of the information that can be retrieved about the shader, in bytes, is returned in **pInfoSize**. Otherwise, **pInfoSize** must point to a variable set by the user to the size of the buffer, in bytes, pointed to by **pInfo**, and on return the variable is overwritten with the amount of data actually written to **pInfo**.

If **pInfoSize** is less than the maximum size that can be retrieved by the pipeline cache, then at most
pDataSize bytes will be written to pInfo, and vkGetShaderInfoAMD will return VK_INCOMPLETE.

Not all information is available for every shader and implementations may not support all kinds of information for any shader. When a certain type of information is unavailable, the function returns VK_ERROR_FEATURE_NOT_PRESENT.

If information is successfully and fully queried, the function will return VK_SUCCESS.

For infoType VK_SHADER_INFO_TYPE_STATISTICS_AMD, a VkShaderStatisticsInfoAMD structure will be written to the buffer pointed to by pInfo. This structure will be populated with statistics regarding the physical device resources used by that shader along with other miscellaneous information and is described in further detail below.

For infoType VK_SHADER_INFO_TYPE_DISASSEMBLY_AMD, pInfo is a pointer to a UTF-8 null-terminated string containing human-readable disassembly. The exact formatting and contents of the disassembly string are vendor-specific.

The formatting and contents of all other types of information, including infoType VK_SHADER_INFO_TYPE_BINARY_AMD, are left to the vendor and are not further specified by this extension.

Valid Usage (Implicit)

- device must be a valid VkDevice handle
- pipeline must be a valid VkPipeline handle
- shaderStage must be a valid VkShaderStageFlagBits value
- infoType must be a valid VkShaderInfoTypeAMD value
- pInfoSize must be a valid pointer to a size_t value
- If the value referenced by pInfoSize is not 0, and pInfo is not NULL, pInfo must be a valid pointer to an array of pInfoSize bytes
- pipeline must have been created, allocated, or retrieved from device

Return Codes

Success

- VK_SUCCESS
- VK_INCOMPLETE

Failure

- VK_ERROR_FEATURE_NOT_PRESENT
- VK_ERROR_OUT_OF_HOST_MEMORY

Possible values of vkGetShaderInfoAMD::infoType, specifying the information being queried from a shader, are:
typedef enum VkShaderInfoTypeAMD {
    VK_SHADER_INFO_TYPE_STATISTICS_AMD = 0,
    VK_SHADER_INFO_TYPE_BINARY_AMD = 1,
    VK_SHADER_INFO_TYPE_DISASSEMBLY_AMD = 2,
} VkShaderInfoTypeAMD;

- **VK_SHADER_INFO_TYPE_STATISTICS_AMD** specifies that device resources used by a shader will be queried.
- **VK_SHADER_INFO_TYPE_BINARY_AMD** specifies that implementation-specific information will be queried.
- **VK_SHADER_INFO_TYPE_DISASSEMBLY_AMD** specifies that human-readable disassembly of a shader.

The **VkShaderStatisticsInfoAMD** structure is defined as:

typedef struct VkShaderStatisticsInfoAMD {
    VkShaderStageFlags shaderStageMask;
    VkShaderResourceUsageAMD resourceUsage;
    uint32_t numPhysicalVgprs;
    uint32_t numPhysicalSgprs;
    uint32_t numAvailableVgprs;
    uint32_t numAvailableSgprs;
    uint32_t computeWorkGroupSize[3];
} VkShaderStatisticsInfoAMD;

- **shaderStageMask** are the combination of logical shader stages contained within this shader.
- **resourceUsage** is a **VkShaderResourceUsageAMD** structure describing internal physical device resources used by this shader.
- **numPhysicalVgprs** is the maximum number of vector instruction general-purpose registers (VGPRs) available to the physical device.
- **numPhysicalSgprs** is the maximum number of scalar instruction general-purpose registers (SGPRs) available to the physical device.
- **numAvailableVgprs** is the maximum limit of VGPRs made available to the shader compiler.
- **numAvailableSgprs** is the maximum limit of SGPRs made available to the shader compiler.
- **computeWorkGroupSize** is the local workgroup size of this shader in \{ X, Y, Z \} dimensions.

Some implementations may merge multiple logical shader stages together in a single shader. In such cases, **shaderStageMask** will contain a bitmask of all of the stages that are active within that shader. Consequently, if specifying those stages as input to **vkGetShaderInfoAMD**, the same output information **may** be returned for all such shader stage queries.

The number of available VGPRs and SGPRs (**numAvailableVgprs** and **numAvailableSgprs** respectively) are the shader-addressable subset of physical registers that is given as a limit to the compiler for register assignment. These values **may** further be limited by implementations due to performance optimizations where register pressure is a bottleneck.
The `VkShaderResourceUsageAMD` structure is defined as:

```c
typedef struct VkShaderResourceUsageAMD {
    uint32_t    numUsedVgprs;
    uint32_t    numUsedSgprs;
    uint32_t    ldsSizePerLocalWorkGroup;
    size_t      ldsUsageSizeInBytes;
    size_t      scratchMemUsageInBytes;
} VkShaderResourceUsageAMD;
```

- `numUsedVgprs` is the number of vector instruction general-purpose registers used by this shader.
- `numUsedSgprs` is the number of scalar instruction general-purpose registers used by this shader.
- `ldsSizePerLocalWorkGroup` is the maximum local data store size per work group in bytes.
- `ldsUsageSizeInBytes` is the LDS usage size in bytes per work group by this shader.
- `scratchMemUsageInBytes` is the scratch memory usage in bytes by this shader.

### 9.12. Pipeline Compiler Control

The compilation of a pipeline can be tuned by adding a `VkPipelineCompilerControlCreateInfoAMD` structure to the `pNext` chain of `VkGraphicsPipelineCreateInfo` or `VkComputePipelineCreateInfo`.

```c
typedef struct VkPipelineCompilerControlCreateInfoAMD {
    VkStructureType                      sType;
    const void*                          pNext;
    VkPipelineCompilerControlFlagsAMD    compilerControlFlags;
} VkPipelineCompilerControlCreateInfoAMD;
```

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `compilerControlFlags` is a bitmask of `VkPipelineCompilerControlFlagBitsAMD` affecting how the pipeline will be compiled.

#### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_PIPELINE_COMPILER_CONTROL_CREATE_INFO_AMD`
- `compilerControlFlags` must be 0

There are currently no available flags for this extension; flags will be added by future versions of this extension.

```c
typedef enum VkPipelineCompilerControlFlagBitsAMD {
} VkPipelineCompilerControlFlagBitsAMD;
```
9.13. Ray Tracing Pipeline

Ray tracing pipelines consist of multiple shader stages, fixed-function traversal stages, and a pipeline layout.

To create ray tracing pipelines, call:

```c
VkResult vkCreateRayTracingPipelinesNV(
    VkDevice                                    device,  // device is the logical device that creates the ray tracing pipelines.
    VkPipelineCache                             pipelineCache,  // pipelineCache is either VK_NULL_HANDLE, indicating that pipeline caching is disabled, or the handle of a valid pipeline cache object, in which case use of that cache is enabled for the duration of the command.
    uint32_t                                    createInfoCount,  // createInfoCount is the length of the pCreateInfos and pPipelines arrays.
    const VkRayTracingPipelineCreateInfoNV*     pCreateInfos,  // pCreateInfos is a pointer to an array of VkRayTracingPipelineCreateInfoNV structures.
    const VkAllocationCallbacks*                pAllocator,  // pAllocator controls host memory allocation as described in the Memory Allocation chapter.
    VkPipeline*                                 pPipelines);  // pPipelines is a pointer to an array in which the resulting ray tracing pipeline objects are returned.
```

**Valid Usage**

- If the flags member of any element of pCreateInfos contains the VK_PIPELINE_CREATE_DERIVATIVE_BIT flag, and the basePipelineIndex member of that same element is not -1, basePipelineIndex must be less than the index into pCreateInfos that corresponds to that element.

- If the flags member of any element of pCreateInfos contains the VK_PIPELINE_CREATE_DERIVATIVE_BIT flag, the base pipeline must have been created with the VK_PIPELINE_CREATE_ALLOW_DERIVATIVES_BIT flag set.

- If pipelineCache was created with VK_PIPELINE_CACHE_CREATE_EXTERNALLY_SYNCHRONIZED_BIT_EXT, host access to pipelineCache must be externally synchronized.
Valid Usage (Implicit)

- **device** must be a valid VkDevice handle
- If pipelineCache is not VK_NULL_HANDLE, pipelineCache must be a valid VkPipelineCache handle
- **pCreateInfos** must be a valid pointer to an array of createInfoCount valid VkRayTracingPipelineCreateInfoNV structures
- If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure
- **pPipelines** must be a valid pointer to an array of createInfoCount VkPipeline handles
- createInfoCount must be greater than 0
- If pipelineCache is a valid handle, it must have been created, allocated, or retrieved from device

Return Codes

**Success**
- VK_SUCCESS
- VK_PIPELINE_COMPILE_REQUIRED_EXT

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_INVALID_SHADER_NV

To create ray tracing pipelines, call:

```c
VkResult vkCreateRayTracingPipelinesKHR(
    VkDevice                                    device,
    VkPipelineCache                             pipelineCache,
    uint32_t                                    createInfoCount,
    const VkRayTracingPipelineCreateInfoKHR*    pCreateInfos,
    const VkAllocationCallbacks*                pAllocator,
    VkPipeline*                                 pPipelines);
```

- **device** is the logical device that creates the ray tracing pipelines.
- pipelineCache is either VK_NULL_HANDLE, indicating that pipeline caching is disabled, or the handle of a valid pipeline cache object, in which case use of that cache is enabled for the duration of the command.
- createInfoCount is the length of the pCreateInfos and pPipelines arrays.
- pCreateInfos is a pointer to an array of VkRayTracingPipelineCreateInfoKHR structures.
• `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

• `pPipelines` is a pointer to an array in which the resulting ray tracing pipeline objects are returned.

The `VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS` error is returned if the implementation is unable to re-use the shader group handles provided in `VkRayTracingShaderGroupCreateInfoKHR::pShaderGroupCaptureReplayHandle` when `VkPhysicalDeviceRayTracingFeaturesKHR::rayTracingShaderGroupHandleCaptureReplay` is enabled.

### Valid Usage

- If the `flags` member of any element of `pCreateInfos` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and the `basePipelineIndex` member of that same element is not -1, `basePipelineIndex` must be less than the index into `pCreateInfos` that corresponds to that element.

- If the `flags` member of any element of `pCreateInfos` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, the base pipeline must have been created with the `VK_PIPELINE_CREATE_ALLOW_DERIVATIVES_BIT` flag set.

- If `pipelineCache` was created with `VK_PIPELINE_CACHE_CREATE_EXTERNALLY_SYNCHRONIZED_BIT_EXT`, host access to `pipelineCache` must be externally synchronized.

- The rayTracing feature must be enabled.

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle.

- If `pipelineCache` is not `VK_NULL_HANDLE`, `pipelineCache` must be a valid `VkPipelineCache` handle.

- `pCreateInfos` must be a valid pointer to an array of `createInfoCount` valid `VkRayTracingPipelineCreateInfoKHR` structures.

- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure.

- `pPipelines` must be a valid pointer to an array of `createInfoCount` `VkPipeline` handles.

- `createInfoCount` must be greater than 0.

- If `pipelineCache` is a valid handle, it must have been created, allocated, or retrieved from `device`.
Return Codes

Success
- VK_SUCCESS
- VK_OPERATION_DEFERRED_KHR
- VK_OPERATION_NOT_DEFERRED_KHR
- VK_PIPELINE_COMPILE_REQUIRED_EXT

Failure
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS

The VkRayTracingPipelineCreateInfoNV structure is defined as:

```c
typedef struct VkRayTracingPipelineCreateInfoNV {
    VkStructureType sType;
    const void* pNext;
    VkPipelineCreateFlags flags;
    uint32_t stageCount;
    const VkPipelineShaderStageCreateInfo* pStages;
    uint32_t groupCount;
    const VkRayTracingShaderGroupCreateInfoNV* pGroups;
    uint32_t maxRecursionDepth;
    VkPipelineLayout layout;
    VkPipeline basePipelineHandle;
    int32_t basePipelineIndex;
} VkRayTracingPipelineCreateInfoNV;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `flags` is a bitmask of VkPipelineCreateFlagBits specifying how the pipeline will be generated.
- `stageCount` is the number of entries in the `pStages` array.
- `pStages` is an array of size `stageCount` structures of type VkPipelineShaderStageCreateInfo describing the set of the shader stages to be included in the ray tracing pipeline.
- `groupCount` is the number of entries in the `pGroups` array.
- `pGroups` is an array of size `groupCount` structures of type VkRayTracingShaderGroupCreateInfoNV describing the set of the shader stages to be included in each shader group in the ray tracing pipeline.
- `maxRecursionDepth` is the maximum recursion depth of shaders executed by this pipeline.
- `layout` is the description of binding locations used by both the pipeline and descriptor sets used
with the pipeline.

- **basePipelineHandle** is a pipeline to derive from.
- **basePipelineIndex** is an index into the `pCreateInfos` parameter to use as a pipeline to derive from.

The parameters **basePipelineHandle** and **basePipelineIndex** are described in more detail in **Pipeline Derivatives**.
Valid Usage

- If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineIndex` is -1, `basePipelineHandle` must be a valid handle to a ray tracing `VkPipeline`.

- If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineHandle` is `VK_NULL_HANDLE`, `basePipelineIndex` must be a valid index into the calling command's `pCreateInfos` parameter.

- If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineIndex` is not -1, `basePipelineHandle` must be `VK_NULL_HANDLE`.

- If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineHandle` is not `VK_NULL_HANDLE`, `basePipelineIndex` must be -1.

- The `stage` member of at least one element of `pStages` must be `VK_SHADER_STAGE_RAYGEN_BIT_KHR`.

- The shader code for the entry points identified by `pStages`, and the rest of the state identified by this structure must adhere to the pipeline linking rules described in the Shader Interfaces chapter.

- `layout` must be consistent with all shaders specified in `pStages`.

- The number of resources in `layout` accessible to each shader stage that is used by the pipeline must be less than or equal to `VkPhysicalDeviceLimits::maxPerStageResources`.

- `flags` must not include `VK_PIPELINE_CREATE_INDIRECT_BINDABLE_BIT_NV`.

- If the `pipelineCreationCacheControl` feature is not enabled, `flags` must not include `VK_PIPELINE_CREATE_FAIL_ON_PIPELINE_COMPILE_REQUIRED_BIT_EXT` or `VK_PIPELINE_CREATE_EARLY_RETURN_ON_FAILURE_BIT_EXT`.

- `flags` must not include `VK_PIPELINE_CREATE_LIBRARY_BIT_KHR`.

- `maxRecursionDepth` must be less than or equal to `VkPhysicalDeviceRayTracingPropertiesNV::maxRecursionDepth`.

- `flags` must not include `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_ANY_HIT_SHADERS_BIT_KHR`.

- `flags` must not include `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_CLOSEST_HIT_SHADERS_BIT_KHR`.

- `flags` must not include `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_MISS_SHADERS_BIT_KHR`.

- `flags` must not include `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_INTERSECTION_SHADERS_BIT_KHR`.

- `flags` must not include `VK_PIPELINE_CREATE_RAY_TRACING_SKIP_AABBS_BIT_KHR`.

- `flags` must not include `VK_PIPELINE_CREATE_RAY_TRACING_SKIP_TRIANGLES_BIT_KHR`.

- `flags` must not include both `VK_PIPELINE_CREATE_DEFER_COMPILE_BIT_NV` and `VK_PIPELINE_CREATE_FAIL_ON_PIPELINE_COMPILE_REQUIRED_BIT_EXT` at the same time.
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_RAY_TRACING_PIPELINE_CREATE_INFO_NV`
- **pNext** must be `NULL` or a pointer to a valid instance of `VkPipelineCreationFeedbackCreateInfoEXT`
- The **sType** value of each struct in the **pNext** chain must be unique
- **flags** must be a valid combination of `VkPipelineCreateFlagBits` values
- **pStages** must be a valid pointer to an array of `stageCount` valid `VkPipelineShaderStageCreateInfo` structures
- **pGroups** must be a valid pointer to an array of `groupCount` valid `VkRayTracingShaderGroupCreateInfoNV` structures
- **layout** must be a valid `VkPipelineLayout` handle
- **stageCount** must be greater than 0
- **groupCount** must be greater than 0
- Both of **basePipelineHandle**, and **layout** that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`

The `VkRayTracingPipelineCreateInfoKHR` structure is defined as:

```c
typedef struct VkRayTracingPipelineCreateInfoKHR {
    VkStructureType                                      sType; // sType
    const void*                                          pNext; // pNext
    VkPipelineCreateFlags                                flags; // flags
    uint32_t                                             stageCount; // stageCount
    const VkPipelineShaderStageCreateInfo*               pStages; // pStages
    uint32_t                                             groupCount; // groupCount
    const VkRayTracingShaderGroupCreateInfoKHR*          pGroups; // pGroups
    uint32_t                                             maxRecursionDepth; // maxRecursionDepth
    VkPipelineLibraryCreateInfoKHR                       libraries; // libraries
    const VkRayTracingPipelineInterfaceCreateInfoKHR*    pLibraryInterface; // pLibraryInterface
    VkPipelineLayout                                     layout; // layout
    VkPipeline                                           basePipelineHandle; // basePipelineHandle
    int32_t                                              basePipelineIndex; // basePipelineIndex
} VkRayTracingPipelineCreateInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkPipelineCreateFlagBits` specifying how the pipeline will be generated.
- **stageCount** is the number of entries in the **pStages** array.
- **pStages** is a pointer to an array of `stageCount` `VkPipelineShaderStageCreateInfo` structures describing the set of the shader stages to be included in the ray tracing pipeline.
• **groupCount** is the number of entries in the **pGroups** array.

• **pGroups** is a pointer to an array of **groupCount** **VkRayTracingShaderGroupCreateInfoKHR** structures describing the set of the shader stages to be included in each shader group in the ray tracing pipeline.

• **maxRecursionDepth** is the **maximum recursion depth** of shaders executed by this pipeline.

• **libraries** is a **VkPipelineLibraryCreateInfoKHR** structure defining pipeline libraries to include.

• **pLibraryInterface** is a pointer to a **VkRayTracingPipelineInterfaceCreateInfoKHR** structure defining additional information when using pipeline libraries.

• **layout** is the description of binding locations used by both the pipeline and descriptor sets used with the pipeline.

• **basePipelineHandle** is a pipeline to derive from.

• **basePipelineIndex** is an index into the **pCreateInfos** parameter to use as a pipeline to derive from.

The parameters **basePipelineHandle** and **basePipelineIndex** are described in more detail in **Pipeline Derivatives**.

When **VK_PIPELINE_CREATE_LIBRARY_BIT_KHR** is specified, this pipeline defines a **pipeline library** which **cannot** be bound as a ray tracing pipeline directly. Instead, pipeline libraries define common shaders and shader groups which **can** be included in future pipeline creation.

If pipeline libraries are included in **libraries**, shaders defined in those libraries are treated as if they were defined as additional entries in **pStages**, appended in the order they appear in the **pLibraries** array and in the **pStages** array when those libraries were defined.

When referencing shader groups in order to obtain a shader group handle, groups defined in those libraries are treated as if they were defined as additional entries in **pGroups**, appended in the order they appear in the **pLibraries** array and in the **pGroups** array when those libraries were defined. The shaders these groups reference are set when the pipeline library is created, referencing those specified in the pipeline library, not in the pipeline that includes it.

If the **VkDeferredOperationInfoKHR** structure is included in the **pNext** chain of **VkRayTracingPipelineCreateInfoKHR**, the operation of this pipeline creation is **deferred**, as defined in the **Deferred Host Operations** chapter.
Valid Usage

- If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineIndex` is -1, `basePipelineHandle` must be a valid handle to a ray tracing `VkPipeline`.

- If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineHandle` is `VK_NULL_HANDLE`, `basePipelineIndex` must be a valid index into the calling command's `pCreateInfos` parameter.

- If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineHandle` is not `VK_NULL_HANDLE`, `basePipelineIndex` must be `-1`.

- If `flags` contains the `VK_PIPELINE_CREATE_DERIVATIVE_BIT` flag, and `basePipelineIndex` is not `-1`, `basePipelineHandle` must be `VK_NULL_HANDLE`.

- The stage member of at least one element of `pStages` must be `VK_SHADER_STAGE_RAYGEN_BIT_KHR`.

- The shader code for the entry points identified by `pStages`, and the rest of the state identified by this structure must adhere to the pipeline linking rules described in the Shader Interfaces chapter.

- `layout` must be consistent with all shaders specified in `pStages`.

- The number of resources in `layout` accessible to each shader stage that is used by the pipeline must be less than or equal to `VkPhysicalDeviceLimits::maxPerStageResources`.

- `flags` must not include `VK_PIPELINE_CREATE_INDIRECT_BINDABLE_BIT_NV`.

- If the `pipelineCreationCacheControl` feature is not enabled, `flags` must not include `VK_PIPELINE_CREATE_FAIL_ON_PIPELINE_COMPILE_REQUIRED_BIT_EXT` or `VK_PIPELINE_CREATE_EARLY_RETURN_ON_FAILURE_BIT_EXT`.

- `maxRecursionDepth` must be less than or equal to `VkPhysicalDeviceRayTracingPropertiesKHR::maxRecursionDepth`.

- If `flags` includes `VK_PIPELINE_CREATE_LIBRARY_BIT_KHR`, `pLibraryInterface` must not be `NULL`.

- If the `libraryCount` member of `libraries` is greater than 0, `pLibraryInterface` must not be `NULL`.

- Each element of the `pLibraries` member of `libraries` must have been created with the value of `maxRecursionDepth` equal to that in this pipeline.

- Each element of the `pLibraries` member of `libraries` must have been created with a `layout` that is compatible with the `layout` in this pipeline.

- Each element of the `pLibraries` member of `libraries` must have been created with values of the `maxPayloadSize`, `maxAttributeSize`, and `maxCallableSize` members of `pLibraryInterface` equal to those in this pipeline.

- If `flags` includes `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_ANY_HIT_SHADERS_BIT_KHR`, for any element of `pGroups` with a type of `VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_KHR` or `VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_KHR`, the anyHitShader of that element must not be `VK_SHADER_UNUSED_KHR`.

- If `flags` includes `VK_PIPELINE_CREATE_RAY_TRACING_NO_NULL_CLOSEST_HIT_SHADERS_BIT_KHR`,...
for any element of \( \text{pGroups} \) with a type of

\[ \text{VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_KHR} \]

or

\[ \text{VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_KHR} \]

the closestHitShader of that element must not be \( \text{VK_SHADER_UNUSED_KHR} \).

- If the \( \text{rayTracingPrimitiveCulling} \) feature is not enabled, flags must not include

\[ \text{VK_PIPELINE_CREATE_RAY_TRACING_SKIP_AABBS_BIT_KHR} \]

- If the \( \text{rayTracingPrimitiveCulling} \) feature is not enabled, flags must not include

\[ \text{VK_PIPELINE_CREATE_RAY_TRACING_SKIP_TRIANGLES_BIT_KHR} \]

- If \( \text{libraries.libraryCount} \) is zero, then stageCount must not be zero.

- If \( \text{libraries.libraryCount} \) is zero, then groupCount must not be zero.

### Valid Usage (Implicit)

- **sType** must be \( \text{VK_STRUCTURE_TYPE_RAY_TRACING_PIPELINE_CREATE_INFO_KHR} \)

- Each **pNext** member of any structure (including this one) in the **pNext** chain must be either

\[ \text{NULL} \]

or a pointer to a valid instance of \( \text{VkDeferredOperationInfoKHR} \) or

\( \text{VkPipelineCreationFeedbackCreateInfoEXT} \)

- The **sType** value of each struct in the **pNext** chain must be unique.

- **flags** must be a valid combination of \( \text{VkPipelineCreateFlagBits} \) values.

- If **stageCount** is not 0, **pStages** must be a valid pointer to an array of **stageCount** valid

\( \text{VkPipelineShaderStageCreateInfo} \)

structures.

- If **groupCount** is not 0, **pGroups** must be a valid pointer to an array of **groupCount** valid

\( \text{VkRayTracingShaderGroupCreateInfoKHR} \)

structures.

- **libraries** must be a valid \( \text{VkPipelineLibraryCreateInfoKHR} \) structure.

- If **pLibraryInterface** is not \( \text{NULL} \), **pLibraryInterface** must be a valid pointer to a valid

\( \text{VkRayTracingPipelineInterfaceCreateInfoKHR} \)

structure.

- **layout** must be a valid \( \text{VkPipelineLayout} \) handle.

- Both of **basePipelineHandle**, and **layout** that are valid handles of non-ignored parameters

must have been created, allocated, or retrieved from the same \( \text{VkDevice} \).

The \( \text{VkRayTracingShaderGroupCreateInfoNV} \) structure is defined as:

```c
typedef struct VkRayTracingShaderGroupCreateInfoNV {
    VkStructureType                      sType;
    const void*                           pNext;
    VkRayTracingShaderGroupTypeKHR        type;
    uint32_t                              generalShader;
    uint32_t                              closestHitShader;
    uint32_t                              anyHitShader;
    uint32_t                              intersectionShader;
} VkRayTracingShaderGroupCreateInfoNV;
```
• **sType** is the type of this structure.
• **pNext** is NULL or a pointer to an extension-specific structure.
• **type** is the type of hit group specified in this structure.

  • **generalShader** is the index of the ray generation, miss, or callable shader from `VkRayTracingPipelineCreateInfoNV::pStages` in the group if the shader group has **type** of `VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_NV`, and **VK_SHADER_UNUSED_NV** otherwise.

  • **closestHitShader** is the optional index of the closest hit shader from `VkRayTracingPipelineCreateInfoNV::pStages` in the group if the shader group has **type** of `VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_NV` or `VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_NV`, and **VK_SHADER_UNUSED_NV** otherwise.

  • **anyHitShader** is the optional index of the any-hit shader from `VkRayTracingPipelineCreateInfoNV::pStages` in the group if the shader group has **type** of `VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_NV` or `VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_NV`, and **VK_SHADER_UNUSED_NV** otherwise.

  • **intersectionShader** is the index of the intersection shader from `VkRayTracingPipelineCreateInfoNV::pStages` in the group if the shader group has **type** of `VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_NV`, and **VK_SHADER_UNUSED_NV** otherwise.

### Valid Usage

• If **type** is `VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_NV` then **generalShader** must be a valid index into `VkRayTracingPipelineCreateInfoNV::pStages` referring to a shader of `VK_SHADER_STAGE_RAYGEN_BIT_NV`, `VK_SHADER_STAGE_MISS_BIT_NV`, or `VK_SHADER_STAGE_CALLABLE_BIT_NV`.

• If **type** is `VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_NV` then **closestHitShader**, **anyHitShader**, and **intersectionShader** must be **VK_SHADER_UNUSED_NV**.

• If **type** is `VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_NV` then **intersectionShader** must be a valid index into `VkRayTracingPipelineCreateInfoNV::pStages` referring to a shader of `VK_SHADER_STAGE_INTERSECTION_BIT_NV`.

• If **type** is `VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_NV` then **intersectionShader** must be **VK_SHADER_UNUSED_NV**.

• **closestHitShader** must be either **VK_SHADER_UNUSED_NV** or a valid index into `VkRayTracingPipelineCreateInfoNV::pStages` referring to a shader of `VK_SHADER_STAGE_CLOSEST_HIT_BIT_NV`.

• **anyHitShader** must be either **VK_SHADER_UNUSED_NV** or a valid index into `VkRayTracingPipelineCreateInfoNV::pStages` referring to a shader of `VK_SHADER_STAGE_ANY_HIT_BIT_NV`.

---

440 | Chapter 9. Pipelines
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_RAY_TRACING_SHADER_GROUP_CREATE_INFO_NV`
- **pNext** must be `NULL`
- **type** must be a valid `VkRayTracingShaderGroupTypeKHR` value

The `VkRayTracingShaderGroupCreateInfoKHR` structure is defined as:

```c
typedef struct VkRayTracingShaderGroupCreateInfoKHR {
    VkStructureType                   sType;
    const void*                       pNext;
    VkRayTracingShaderGroupTypeKHR    type;
    uint32_t                          generalShader;
    uint32_t                          closestHitShader;
    uint32_t                          anyHitShader;
    uint32_t                          intersectionShader;
    const void*                       pShaderGroupCaptureReplayHandle;
} VkRayTracingShaderGroupCreateInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **type** is the type of hit group specified in this structure.
- **generalShader** is the index of the ray generation, miss, or callable shader from `VkRayTracingPipelineCreateInfoKHR::pStages` in the group if the shader group has `type` of `VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_KHR`, and `VK_SHADER_UNUSED_KHR` otherwise.
- **closestHitShader** is the optional index of the closest hit shader from `VkRayTracingPipelineCreateInfoKHR::pStages` in the group if the shader group has `type` of `VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_KHR` or `VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_KHR`, and `VK_SHADER_UNUSED_KHR` otherwise.
- **anyHitShader** is the optional index of the any-hit shader from `VkRayTracingPipelineCreateInfoKHR::pStages` in the group if the shader group has `type` of `VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_KHR` or `VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_KHR`, and `VK_SHADER_UNUSED_KHR` otherwise.
- **intersectionShader** is the index of the intersection shader from `VkRayTracingPipelineCreateInfoKHR::pStages` in the group if the shader group has `type` of `VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_KHR`, and `VK_SHADER_UNUSED_KHR` otherwise.
- **pShaderGroupCaptureReplayHandle** is an optional pointer to replay information for this shader group. Ignored if `VkPhysicalDeviceRayTracingFeaturesKHR::rayTracingShaderGroupHandleCaptureReplay` is `VK_FALSE`. 
Valid Usage

• If `type` is `VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_KHR` then `generalShader` must be a valid index into `VkRayTracingPipelineCreateInfoKHR::pStages` referring to a shader of `VK_SHADER_STAGE_RAYGEN_BIT_KHR`, `VK_SHADER_STAGE_MISS_BIT_KHR`, or `VK_SHADER_STAGE_CALLABLE_BIT_KHR`.

• If `type` is `VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_KHR` then `closestHitShader`, `anyHitShader`, and `intersectionShader` must be `VK_SHADER_UNUSED_KHR`.

• If `type` is `VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_KHR` then `intersectionShader` must be a valid index into `VkRayTracingPipelineCreateInfoKHR::pStages` referring to a shader of `VK_SHADER_STAGE_INTERSECTION_BIT_KHR`.

• If `type` is `VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_KHR` then `intersectionShader` must be `VK_SHADER_UNUSED_KHR`.

• `closestHitShader` must be either `VK_SHADER_UNUSED_KHR` or a valid index into `VkRayTracingPipelineCreateInfoKHR::pStages` referring to a shader of `VK_SHADER_STAGE_CLOSEST_HIT_BIT_KHR`.

• `anyHitShader` must be either `VK_SHADER_UNUSED_KHR` or a valid index into `VkRayTracingPipelineCreateInfoKHR::pStages` referring to a shader of `VK_SHADER_STAGE_ANY_HIT_BIT_KHR`.

• If `VkPhysicalDeviceRayTracingFeaturesKHR::rayTracingShaderGroupHandleCaptureReplayMixed` is `VK_FALSE` then `pShaderGroupCaptureReplayHandle` must not be provided if it has not been provided on a previous call to ray tracing pipeline creation.

• If `VkPhysicalDeviceRayTracingFeaturesKHR::rayTracingShaderGroupHandleCaptureReplayMixed` is `VK_FALSE` then the caller must guarantee that no ray tracing pipeline creation commands with `pShaderGroupCaptureReplayHandle` provided execute simultaneously with ray tracing pipeline creation commands without `pShaderGroupCaptureReplayHandle` provided.

Valid Usage (Implicit)

• `sType` must be `VK_STRUCTURE_TYPE_RAY_TRACING_SHADER_GROUP_CREATE_INFO_KHR`.

• `pNext` must be `NULL`.

• `type` must be a valid `VkRayTracingShaderGroupTypeKHR` value.

Possible values of `type` in `VkRayTracingShaderGroupCreateInfoKHR` are:
typedef enum VkRayTracingShaderGroupTypeKHR {
    VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_KHR = 0,
    VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_KHR = 1,
    VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_KHR = 2,
    VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_NV =
    VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_KHR,
    VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_NV =
    VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_KHR,
    VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_NV =
    VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_KHR,
} VkRayTracingShaderGroupTypeKHR;

or the equivalent

typedef VkRayTracingShaderGroupTypeKHR VkRayTracingShaderGroupTypeNV;

• VK_RAY_TRACING_SHADER_GROUP_TYPE_GENERAL_KHR indicates a shader group with a single
  VK_SHADER_STAGE_RAYGEN_BIT_KHR, VK_SHADER_STAGE_MISS_BIT_KHR, or
  VK_SHADER_STAGE_CALLABLE_BIT_KHR shader in it.

• VK_RAY_TRACING_SHADER_GROUP_TYPE_TRIANGLES_HIT_GROUP_KHR specifies a shader group that only
  hits triangles and must not contain an intersection shader, only closest hit and any-hit shaders.

• VK_RAY_TRACING_SHADER_GROUP_TYPE_PROCEDURAL_HIT_GROUP_KHR specifies a shader group that only
  intersects with custom geometry and must contain an intersection shader and may contain
  closest hit and any-hit shaders.

Note
For current group types, the hit group type could be inferred from the presence or
absence of the intersection shader, but we provide the type explicitly for future hit
groups that do not have that property.

The VkRayTracingPipelineInterfaceCreateInfoKHR structure is defined as:

typedef struct VkRayTracingPipelineInterfaceCreateInfoKHR {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           maxPayloadSize;
    uint32_t           maxAttributeSize;
    uint32_t           maxCallableSize;
} VkRayTracingPipelineInterfaceCreateInfoKHR;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• maxPayloadSize is the maximum payload size in bytes used by any shader in the pipeline.
• maxAttributeSize is the maximum attribute structure size in bytes used by any shader in the
maxCallableSize is the maximum callable data size in bytes used by any shader in the pipeline.

maxPayloadSize is calculated as the maximum number of bytes used by any block declared in the RayPayloadKHR or IncomingRayPayloadKHR storage classes. maxAttributeSize is calculated as the maximum number of bytes used by any block declared in the HitAttributeKHR storage class. maxCallableSize is calculated as the maximum number of bytes used by any block declared in the CallableDataKHR or IncomingCallableDataKHR. As variables in these storage classes do not have explicit offsets, the size should be calculated as if each variable has a scalar alignment equal to the largest scalar alignment of any of the block’s members.

Valid Usage (Implicit)

- **sType** must be VK_STRUCTURE_TYPE_RAY_TRACING_PIPELINE_INTERFACE_CREATE_INFO_KHR
- **pNext** must be NULL

To query the opaque handles of shaders in the ray tracing pipeline, call:

```c
VkResult vkGetRayTracingShaderGroupHandlesKHR(
    VkDevice device,                   // device,
    VkPipeline pipeline,              // pipeline,
    uint32_t firstGroup,              // firstGroup,
    uint32_t groupCount,              // groupCount,
    size_t dataSize,                 // dataSize,
    void* pData);                     // pData);
```

or the equivalent command

```c
VkResult vkGetRayTracingShaderGroupHandlesNV(
    VkDevice device,                   // device,
    VkPipeline pipeline,              // pipeline,
    uint32_t firstGroup,              // firstGroup,
    uint32_t groupCount,              // groupCount,
    size_t dataSize,                 // dataSize,
    void* pData);                     // pData);
```

- **device** is the logical device containing the ray tracing pipeline.
- **pipeline** is the ray tracing pipeline object containing the shaders.
- **firstGroup** is the index of the first group to retrieve a handle for from the VkRayTracingPipelineCreateInfoKHR::pGroups or VkRayTracingPipelineCreateInfoNV::pGroups array.
- **groupCount** is the number of shader handles to retrieve.
- **dataSize** is the size in bytes of the buffer pointed to by pData.
pData is a pointer to a user-allocated buffer where the results will be written.

**Valid Usage**

- **firstGroup** must be less than the number of shader groups in pipeline
- The sum of **firstGroup** and **groupCount** must be less than or equal to the number of shader groups in pipeline
- **dataSize** must be at least VkPhysicalDeviceRayTracingPropertiesKHR::shaderGroupHandleSize \times groupCount
- pipeline must have not been created with VK_PIPELINE_CREATE_LIBRARY_BIT_KHR

**Valid Usage (Implicit)**

- **device** must be a valid VkDevice handle
- **pipeline** must be a valid VkPipeline handle
- pData must be a valid pointer to an array of **dataSize** bytes
- **dataSize** must be greater than 0
- pipeline must have been created, allocated, or retrieved from **device**

**Return Codes**

**Success**

- VK_SUCCESS

**Failure**

- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

To query the optional capture handle information of shaders in the ray tracing pipeline, call:

```
VkResult vkGetRayTracingCaptureReplayShaderGroupHandlesKHR(
    VkDevice                                    device,    
    VkPipeline                                  pipeline,  
    uint32_t                                    firstGroup, 
    uint32_t                                    groupCount,  
    size_t                                      dataSize,   
    void*                                       pData);    
```

- **device** is the logical device containing the ray tracing pipeline.
- **pipeline** is the ray tracing pipeline object containing the shaders.
• **firstGroup** is the index of the first group to retrieve a handle for from the *VkRayTracingPipelineCreateInfoKHR::pGroups* array.

• **groupCount** is the number of shader handles to retrieve.

• **dataSize** is the size in bytes of the buffer pointed to by *pData*.

• **pData** is a pointer to a user-allocated buffer where the results will be written.

---

**Valid Usage**

- **firstGroup must** be less than the number of shader groups in *pipeline*

- The sum of **firstGroup** and **groupCount must** be less than or equal to the number of shader groups in *pipeline*

- **dataSize must** be at least \( \text{VkPhysicalDeviceRayTracingPropertiesKHR::shaderGroupHandleCaptureReplaySize} \times \text{groupCount} \)

- **VkPhysicalDeviceRayTracingFeaturesKHR::rayTracingShaderGroupHandleCaptureReplay** must be enabled to call this function

---

**Valid Usage (Implicit)**

- **device must** be a valid *VkDevice* handle

- **pipeline must** be a valid *VkPipeline* handle

- **pData must** be a valid pointer to an array of **dataSize** bytes

- **dataSize must** be greater than \( 0 \)

- **pipeline must** have been created, allocated, or retrieved from *device*

---

**Return Codes**

**Success**

- **VK_SUCCESS**

**Failure**

- **VK_ERROR_OUT_OF_HOST_MEMORY**

- **VK_ERROR_OUT_OF_DEVICE_MEMORY**

Ray tracing pipelines **can** contain more shaders than a graphics or compute pipeline, so to allow parallel compilation of shaders within a pipeline, an application **can** choose to defer compilation until a later point in time.

To compile a deferred shader in a pipeline call:
VkResult vkCompileDeferredNV(
    VkDevice                                    device,
    VkPipeline                                  pipeline,
    uint32_t                                    shader);

• device is the logical device containing the ray tracing pipeline.
• pipeline is the ray tracing pipeline object containing the shaders.
• shader is the index of the shader to compile.

Valid Usage
• pipeline must have been created with VK_PIPELINE_CREATE_DEFER_COMPILE_BIT_NV
• shader must not have been called as a deferred compile before

Valid Usage (Implicit)
• device must be a valid VkDevice handle
• pipeline must be a valid VkPipeline handle
• pipeline must have been created, allocated, or retrieved from device

Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

Feedback about the creation of a particular pipeline object can be obtained by adding a
VkPipelineCreationFeedbackCreateInfoEXT structure to the pNext chain of
VkGraphicsPipelineCreateInfo, VkRayTracingPipelineCreateInfoKHR,
VkRayTracingPipelineCreateInfoNV, or VkComputePipelineCreateInfo. The
VkPipelineCreationFeedbackCreateInfoEXT structure is defined as:
typedef struct VkPipelineCreationFeedbackCreateInfoEXT {
    VkStructureType sType;
    const void* pNext;
    VkPipelineCreationFeedbackEXT* pPipelineCreationFeedback;
    uint32_t pipelineStageCreationFeedbackCount;
    VkPipelineCreationFeedbackEXT* pPipelineStageCreationFeedbacks;
} VkPipelineCreationFeedbackCreateInfoEXT;

• `sType` is the type of this structure.
• `pNext` is `NULL` or a pointer to an extension-specific structure.
• `pPipelineCreationFeedback` is a pointer to a `VkPipelineCreationFeedbackEXT` structure.
• `pipelineStageCreationFeedbackCount` is the number of elements in `pPipelineStageCreationFeedbacks`.
• `pPipelineStageCreationFeedbacks` is a pointer to an array of `pipelineStageCreationFeedbackCount` `VkPipelineCreationFeedbackEXT` structures.

An implementation **should** write pipeline creation feedback to `pPipelineCreationFeedback` and **may** write pipeline stage creation feedback to `pPipelineStageCreationFeedbacks`. An implementation **must** set or clear the `VK_PIPELINE_CREATION_FEEDBACK_VALID_BIT_EXT` in `VkPipelineCreationFeedbackEXT::flags` for `pPipelineCreationFeedback` and every element of `pPipelineStageCreationFeedbacks`.

**Note**

One common scenario for an implementation to skip per-stage feedback is when `VK_PIPELINE_CREATION_FEEDBACK_APPLICATION_PIPELINE_CACHE_HIT_BIT_EXT` is set in `pPipelineCreationFeedback`.

When chained to `VkRayTracingPipelineCreateInfoKHR`, `VkRayTracingPipelineCreateInfoNV`, or `VkGraphicsPipelineCreateInfo`, the `i` element of `pPipelineStageCreationFeedbacks` corresponds to the `i` element of `VkRayTracingPipelineCreateInfoKHR::pStages`, `VkRayTracingPipelineCreateInfoNV::pStages`, or `VkGraphicsPipelineCreateInfo::pStages`. When chained to `VkComputePipelineCreateInfo`, the first element of `pPipelineStageCreationFeedbacks` corresponds to `VkComputePipelineCreateInfo::stage`. 
Valid Usage

- When chained to `VkGraphicsPipelineCreateInfo`, `VkPipelineCreationFeedbackEXT::pipelineStageCreationFeedbackCount` must equal `VkGraphicsPipelineCreateInfo::stageCount`
- When chained to `VkComputePipelineCreateInfo`, `VkPipelineCreationFeedbackEXT::pipelineStageCreationFeedbackCount` must equal 1
- When chained to `VkRayTracingPipelineCreateInfoKHR`, `VkPipelineCreationFeedbackEXT::pipelineStageCreationFeedbackCount` must equal `VkRayTracingPipelineCreateInfoKHR::stageCount`
- When chained to `VkRayTracingPipelineCreateInfoNV`, `VkPipelineCreationFeedbackEXT::pipelineStageCreationFeedbackCount` must equal `VkRayTracingPipelineCreateInfoNV::stageCount`

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_PIPELINE_CREATION_FEEDBACK_CREATE_INFO_EXT`
- `pPipelineCreationFeedback` must be a valid pointer to a `VkPipelineCreationFeedbackEXT` structure
- `pPipelineStageCreationFeedbacks` must be a valid pointer to an array of `pipelineStageCreationFeedbackCount` `VkPipelineCreationFeedbackEXT` structures
- `pipelineStageCreationFeedbackCount` must be greater than 0

The `VkPipelineCreationFeedbackEXT` structure is defined as:

```c
typedef struct VkPipelineCreationFeedbackEXT {
    VkPipelineCreationFeedbackFlagsEXT flags;
    uint64_t duration;
} VkPipelineCreationFeedbackEXT;
```

- `flags` is a bitmask of `VkPipelineCreationFeedbackFlagBitsEXT` providing feedback about the creation of a pipeline or of a pipeline stage.
- `duration` is the duration spent creating a pipeline or pipeline stage in nanoseconds.

If the `VK_PIPELINE_CREATION_FEEDBACK_VALID_BIT_EXT` is not set in `flags`, an implementation must not set any other bits in `flags`, and all other `VkPipelineCreationFeedbackEXT` data members are undefined.

Possible values of the `flags` member of `VkPipelineCreationFeedbackEXT` are:
```c
typedef enum VkPipelineCreationFeedbackFlagBitsEXT {
    VK_PIPELINE_CREATION_FEEDBACK_VALID_BIT_EXT = 0x00000001,
    VK_PIPELINE_CREATION_FEEDBACK_APPLICATION_PIPELINE_CACHE_HIT_BIT_EXT = 0x00000002,
    VK_PIPELINE_CREATION_FEEDBACK_BASE_PIPELINE ACCELERATION_BIT_EXT = 0x00000004,
} VkPipelineCreationFeedbackFlagBitsEXT;
```

- **VK_PIPELINE_CREATION_FEEDBACK_VALID_BIT_EXT** indicates that the feedback information is valid.
- **VK_PIPELINE_CREATION_FEEDBACK_APPLICATION_PIPELINE_CACHE_HIT_BIT_EXT** indicates that a readily usable pipeline or pipeline stage was found in the pipelineCache specified by the application in the pipeline creation command.

An implementation should set the **VK_PIPELINE_CREATION_FEEDBACK_APPLICATION_PIPELINE_CACHE_HIT_BIT_EXT** bit if it was able to avoid the large majority of pipeline or pipeline stage creation work by using the pipelineCache parameter of `vkCreateGraphicsPipelines`, `vkCreateRayTracingPipelinesKHR`, `vkCreateRayTracingPipelinesNV`, or `vkCreateComputePipelines`. When an implementation sets this bit for the entire pipeline, it may leave it unset for any stage.

*Note*
Implementations are encouraged to provide a meaningful signal to applications using this bit. The intention is to communicate to the application that the pipeline or pipeline stage was created "as fast as it gets" using the pipeline cache provided by the application. If an implementation uses an internal cache, it is discouraged from setting this bit as the feedback would be unactionable.

- **VK_PIPELINE_CREATION_FEEDBACK_BASE_PIPELINE_ACCELERATION_BIT_EXT** indicates that the base pipeline specified by the basePipelineHandle or basePipelineIndex member of the Vk*PipelineCreateInfo structure was used to accelerate the creation of the pipeline.

An implementation should set the **VK_PIPELINE_CREATION_FEEDBACK_BASE_PIPELINE_ACCELERATION_BIT_EXT** bit if it was able to avoid a significant amount of work by using the base pipeline.

*Note*
While "significant amount of work" is subjective, implementations are encouraged to provide a meaningful signal to applications using this bit. For example, a 1% reduction in duration may not warrant setting this bit, while a 50% reduction would.

```c
typedef VkFlags VkPipelineCreationFeedbackFlagsEXT;
```

**VkPipelineCreationFeedbackFlagsEXT** is a bitmask type for providing zero or more **VkPipelineCreationFeedbackFlagBitsEXT**.

---

450 | Chapter 9. Pipelines
Chapter 10. Memory Allocation

Vulkan memory is broken up into two categories, *host memory* and *device memory*.

10.1. Host Memory

Host memory is memory needed by the Vulkan implementation for non-device-visible storage.

**Note**

This memory *may* be used to store the implementation’s representation and state of Vulkan objects.

Vulkan provides applications the opportunity to perform host memory allocations on behalf of the Vulkan implementation. If this feature is not used, the implementation will perform its own memory allocations. Since most memory allocations are off the critical path, this is not meant as a performance feature. Rather, this *can* be useful for certain embedded systems, for debugging purposes (e.g. putting a guard page after all host allocations), or for memory allocation logging.

Allocators are provided by the application as a pointer to a `VkAllocationCallbacks` structure:

```c
typedef struct VkAllocationCallbacks {
    void* pUserData;
    PFN_vkAllocationFunction pfnAllocation;
    PFN_vkReallocationFunction pfnReallocation;
    PFN_vkFreeFunction pfnFree;
    PFN_vkInternalAllocationNotification pfnInternalAllocation;
    PFN_vkInternalFreeNotification pfnInternalFree;
} VkAllocationCallbacks;
```

- **pUserData** is a value to be interpreted by the implementation of the callbacks. When any of the callbacks in `VkAllocationCallbacks` are called, the Vulkan implementation will pass this value as the first parameter to the callback. This value *can* vary each time an allocator is passed into a command, even when the same object takes an allocator in multiple commands.

- **pfnAllocation** is a `PFN_vkAllocationFunction` pointer to an application-defined memory allocation function.

- **pfnReallocation** is a `PFN_vkReallocationFunction` pointer to an application-defined memory reallocation function.

- **pfnFree** is a `PFN_vkFreeFunction` pointer to an application-defined memory free function.

- **pfnInternalAllocation** is a `PFN_vkInternalAllocationNotification` pointer to an application-defined function that is called by the implementation when the implementation makes internal allocations.

- **pfnInternalFree** is a `PFN_vkInternalFreeNotification` pointer to an application-defined function that is called by the implementation when the implementation frees internal allocations.
Valid Usage

- **pfnAllocation must** be a valid pointer to a valid user-defined `PFN_vkAllocationFunction`
- **pfnReallocation must** be a valid pointer to a valid user-defined `PFN_vkReallocationFunction`
- **pfnFree must** be a valid pointer to a valid user-defined `PFN_vkFreeFunction`
- If either of `pfnInternalAllocation` or `pfnInternalFree` is not `NULL`, both **must** be valid callbacks

The type of **pfnAllocation** is:

```c
typedef void* (VKAPI_PTR *PFN_vkAllocationFunction)(
    void* pData,
    size_t size,
    size_t alignment,
    VkSystemAllocationScope allocationScope);
```

- **pData** is the value specified for `VkAllocationCallbacks::pData` in the allocator specified by the application.
- **size** is the size in bytes of the requested allocation.
- **alignment** is the requested alignment of the allocation in bytes and **must** be a power of two.
- **allocationScope** is a `VkSystemAllocationScope` value specifying the allocation scope of the lifetime of the allocation, as described [here](#).

If **pfnAllocation** is unable to allocate the requested memory, it **must** return `NULL`. If the allocation was successful, it **must** return a valid pointer to memory allocation containing at least `size` bytes, and with the pointer value being a multiple of `alignment`.

**Note**

Correct Vulkan operation **cannot** be assumed if the application does not follow these rules.

For example, **pfnAllocation** (or **pfnReallocation**) could cause termination of running Vulkan instance(s) on a failed allocation for debugging purposes, either directly or indirectly. In these circumstances, it **cannot** be assumed that any part of any affected `VkInstance` objects are going to operate correctly (even `vkDestroyInstance`), and the application **must** ensure it cleans up properly via other means (e.g. process termination).

If **pfnAllocation** returns `NULL`, and if the implementation is unable to continue correct processing of the current command without the requested allocation, it **must** treat this as a runtime error, and generate `VK_ERROR_OUT_OF_HOST_MEMORY` at the appropriate time for the command in which the condition was detected, as described in [Return Codes](#).
If the implementation is able to continue correct processing of the current command without the requested allocation, then it may do so, and must not generate VK_ERROR_OUT_OF_HOST_MEMORY as a result of this failed allocation.

The type of pfnReallocation is:

```c
typedef void* (VKAPI_PTR *PFN_vkReallocationFunction)(
    void* pUserData,           // pUserData is the value specified for VkAllocationCallbacks::pUserData in the allocator specified by the application.
    void* pOriginal,           // pOriginal must be either NULL or a pointer previously returned by pfnReallocation or pfnAllocation of a compatible allocator.
    size_t size,               // size is the size in bytes of the requested allocation.
    size_t alignment,          // alignment is the requested alignment of the allocation in bytes and must be a power of two.
    VkSystemAllocationScope allocationScope); // allocationScope is a VkSystemAllocationScope value specifying the allocation scope of the lifetime of the allocation, as described here.
```

pfnReallocation must return an allocation with enough space for size bytes, and the contents of the original allocation from bytes zero to min(original size, new size) - 1 must be preserved in the returned allocation. If size is larger than the old size, the contents of the additional space are undefined. If satisfying these requirements involves creating a new allocation, then the old allocation should be freed.

If pOriginal is NULL, then pfnReallocation must behave equivalently to a call to PFN_vkAllocationFunction with the same parameter values (without pOriginal).

If size is zero, then pfnReallocation must behave equivalently to a call to PFN_vkFreeFunction with the same pUserData parameter value, and pMemory equal to pOriginal.

If pOriginal is non-NULL, the implementation must ensure that alignment is equal to the alignment used to originally allocate pOriginal.

If this function fails and pOriginal is non-NULL the application must not free the old allocation.

pfnReallocation must follow the same rules for return values as PFN_vkAllocationFunction.

The type of pfnFree is:

```c
typedef void (VKAPI_PTR *PFN_vkFreeFunction)(
    void* pUserData,           // pUserData is the value specified for VkAllocationCallbacks::pUserData in the allocator specified by the application.
    void* pMemory);           // pMemory is the pointer to the memory block to be freed.
```
• **pUserData** is the value specified for `VkAllocationCallbacks::pUserData` in the allocator specified by the application.

• **pMemory** is the allocation to be freed.

**pMemory** may be NULL, which the callback must handle safely. If **pMemory** is non-NULL, it must be a pointer previously allocated by `pfnAllocation` or `pfnReallocation`. The application should free this memory.

The type of **pfInternalAllocation** is:

```c
typedef void (VKAPI_PTR *PFN_vkInternalAllocationNotification)(
    void* pUserData,
    size_t size,
    VkInternalAllocationType allocationType,
    VkSystemAllocationScope allocationScope);
```

• **pUserData** is the value specified for `VkAllocationCallbacks::pUserData` in the allocator specified by the application.

• **size** is the requested size of an allocation.

• **allocationType** is a `VkInternalAllocationType` value specifying the requested type of an allocation.

• **allocationScope** is a `VkSystemAllocationScope` value specifying the allocation scope of the lifetime of the allocation, as described here.

This is a purely informational callback.

The type of **pfInternalFree** is:

```c
typedef void (VKAPI_PTR *PFN_vkInternalFreeNotification)(
    void* pUserData,
    size_t size,
    VkInternalAllocationType allocationType,
    VkSystemAllocationScope allocationScope);
```

• **pUserData** is the value specified for `VkAllocationCallbacks::pUserData` in the allocator specified by the application.

• **size** is the requested size of an allocation.

• **allocationType** is a `VkInternalAllocationType` value specifying the requested type of an allocation.

• **allocationScope** is a `VkSystemAllocationScope` value specifying the allocation scope of the lifetime of the allocation, as described here.

Each allocation has an allocation scope defining its lifetime and which object it is associated with. Possible values passed to the **allocationScope** parameter of the callback functions specified by `VkAllocationCallbacks`, indicating the allocation scope, are:
typedef enum VkSystemAllocationScope {
    VK_SYSTEM_ALLOCATION_SCOPE_COMMAND = 0,
    VK_SYSTEM_ALLOCATION_SCOPE_OBJECT = 1,
    VK_SYSTEM_ALLOCATION_SCOPE_CACHE = 2,
    VK_SYSTEM_ALLOCATION_SCOPE_DEVICE = 3,
    VK_SYSTEM_ALLOCATION_SCOPE_INSTANCE = 4,
} VkSystemAllocationScope;

• **VK_SYSTEM_ALLOCATION_SCOPE_COMMAND** specifies that the allocation is scoped to the duration of the Vulkan command.

• **VK_SYSTEM_ALLOCATION_SCOPE_OBJECT** specifies that the allocation is scoped to the lifetime of the Vulkan object that is being created or used.

• **VK_SYSTEM_ALLOCATION_SCOPE_CACHE** specifies that the allocation is scoped to the lifetime of a VkPipelineCache or VkValidationCacheEXT object.

• **VK_SYSTEM_ALLOCATION_SCOPE_DEVICE** specifies that the allocation is scoped to the lifetime of the Vulkan device.

• **VK_SYSTEM_ALLOCATION_SCOPE_INSTANCE** specifies that the allocation is scoped to the lifetime of the Vulkan instance.

Most Vulkan commands operate on a single object, or there is a sole object that is being created or manipulated. When an allocation uses an allocation scope of **VK_SYSTEM_ALLOCATION_SCOPE_OBJECT** or **VK_SYSTEM_ALLOCATION_SCOPE_CACHE**, the allocation is scoped to the object being created or manipulated.

When an implementation requires host memory, it will make callbacks to the application using the most specific allocator and allocation scope available:

• If an allocation is scoped to the duration of a command, the allocator will use the **VK_SYSTEM_ALLOCATION_SCOPE_COMMAND** allocation scope. The most specific allocator available is used: if the object being created or manipulated has an allocator, that object's allocator will be used, else if the parent VkDevice has an allocator it will be used, else if the parent VkInstance has an allocator it will be used. Else,

• If an allocation is associated with a VkValidationCacheEXT or VkPipelineCache object, the allocator will use the **VK_SYSTEM_ALLOCATION_SCOPE_CACHE** allocation scope. The most specific allocator available is used (cache, else device, else instance). Else,

• If an allocation is scoped to the lifetime of an object, that object is being created or manipulated by the command, and that object’s type is not VkDevice or VkInstance, the allocator will use an allocation scope of **VK_SYSTEM_ALLOCATION_SCOPE_OBJECT**. The most specific allocator available is used (object, else device, else instance). Else,

• If an allocation is scoped to the lifetime of a device, the allocator will use an allocation scope of **VK_SYSTEM_ALLOCATION_SCOPE_DEVICE**. The most specific allocator available is used (device, else instance). Else,

• If the allocation is scoped to the lifetime of an instance and the instance has an allocator, its allocator will be used with an allocation scope of **VK_SYSTEM_ALLOCATION_SCOPE_INSTANCE**.
• Otherwise an implementation will allocate memory through an alternative mechanism that is unspecified.

Objects that are allocated from pools do not specify their own allocator. When an implementation requires host memory for such an object, that memory is sourced from the object’s parent pool’s allocator.

The application is not expected to handle allocating memory that is intended for execution by the host due to the complexities of differing security implementations across multiple platforms. The implementation will allocate such memory internally and invoke an application provided informational callback when these internal allocations are allocated and freed. Upon allocation of executable memory, pfnInternalAllocation will be called. Upon freeing executable memory, pfnInternalFree will be called. An implementation will only call an informational callback for executable memory allocations and frees.

The allocationType parameter to the pfnInternalAllocation and pfnInternalFree functions may be one of the following values:

```c
typedef enum VkInternalAllocationType {
    VK_INTERNAL_ALLOCATION_TYPE_EXECUTABLE = 0,
} VkInternalAllocationType;
```

• VK_INTERNAL_ALLOCATION_TYPE_EXECUTABLE specifies that the allocation is intended for execution by the host.

An implementation must only make calls into an application-provided allocator during the execution of an API command. An implementation must only make calls into an application-provided allocator from the same thread that called the provoking API command. The implementation should not synchronize calls to any of the callbacks. If synchronization is needed, the callbacks must provide it themselves. The informational callbacks are subject to the same restrictions as the allocation callbacks.

If an implementation intends to make calls through a VkAllocationCallbacks structure between the time a vkCreate* command returns and the time a corresponding vkDestroy* command begins, that implementation must save a copy of the allocator before the vkCreate* command returns. The callback functions and any data structures they rely upon must remain valid for the lifetime of the object they are associated with.

If an allocator is provided to a vkCreate* command, a compatible allocator must be provided to the corresponding vkDestroy* command. Two VkAllocationCallbacks structures are compatible if memory allocated with pfnAllocation or pfnReallocation in each can be freed with pfnReallocation or pfnFree in the other. An allocator must not be provided to a vkDestroy* command if an allocator was not provided to the corresponding vkCreate* command.

If a non-NULL allocator is used, the pfnAllocation, pfnReallocation and pfnFree members must be non-NULL and point to valid implementations of the callbacks. An application can choose to not provide informational callbacks by setting both pfnInternalAllocation and pfnInternalFree to NULL. pfnInternalAllocation and pfnInternalFree must either both be NULL or both be non-NULL.
If `pfnAllocation` or `pfnReallocation` fail, the implementation may fail object creation and/or generate a `VK_ERROR_OUT_OF_HOST_MEMORY` error, as appropriate.

Allocation callbacks must not call any Vulkan commands.

The following sets of rules define when an implementation is permitted to call the allocator callbacks.

`pfnAllocation` or `pfnReallocation` may be called in the following situations:

- Allocations scoped to a `VkDevice` or `VkInstance` may be allocated from any API command.
- Allocations scoped to a command may be allocated from any API command.
- Allocations scoped to a `VkPipelineCache` may only be allocated from:
  - `vkCreatePipelineCache`
  - `vkMergePipelineCaches` for `dstCache`
  - `vkCreateGraphicsPipelines` for `pipelineCache`
  - `vkCreateComputePipelines` for `pipelineCache`
- Allocations scoped to a `VkValidationCacheEXT` may only be allocated from:
  - `vkCreateValidationCacheEXT`
  - `vkMergeValidationCachesEXT` for `dstCache`
  - `vkCreateShaderModule` for `validationCache` in `VkShaderModuleValidationCacheCreateInfoEXT`
- Allocations scoped to a `VkDescriptorPool` may only be allocated from:
  - any command that takes the pool as a direct argument
  - `vkAllocateDescriptorSets` for the `descriptorPool` member of its `pAllocateInfo` parameter
  - `vkCreateDescriptorPool`
- Allocations scoped to a `VkCommandPool` may only be allocated from:
  - any command that takes the pool as a direct argument
  - `vkCreateCommandPool`
  - `vkAllocateCommandBuffers` for the `commandPool` member of its `pAllocateInfo` parameter
  - any `vkCmd*` command whose `commandBuffer` was allocated from that `VkCommandPool`
- Allocations scoped to any other object may only be allocated in that object's `vkCreate*` command.

`pfnFree`, or `pfnReallocation` with zero size, may be called in the following situations:

- Allocations scoped to a `VkDevice` or `VkInstance` may be freed from any API command.
- Allocations scoped to a command must be freed by any API command which allocates such memory.
- Allocations scoped to a `VkPipelineCache` may be freed from `vkDestroyPipelineCache`.
- Allocations scoped to a `VkValidationCacheEXT` may be freed from `vkDestroyValidationCacheEXT`.
• Allocations scoped to a VkDescriptorPool **may** be freed from
  ◦ any command that takes the pool as a direct argument
• Allocations scoped to a VkCommandPool **may** be freed from:
  ◦ any command that takes the pool as a direct argument
  ◦ `vkResetCommandBuffer` whose `commandBuffer` was allocated from that VkCommandPool
• Allocations scoped to any other object **may** be freed in that object's `vkDestroy*` command.
• Any command that allocates host memory **may** also free host memory of the same scope.

### 10.2. Device Memory

*Device memory* is memory that is visible to the device — for example the contents of the image or buffer objects, which **can** be natively used by the device.

Memory properties of a physical device describe the memory heaps and memory types available.

To query memory properties, call:

```c
void vkGetPhysicalDeviceMemoryProperties(
    VkPhysicalDevice                            physicalDevice,
    VkPhysicalDeviceMemoryProperties*           pMemoryProperties);
```

• **physicalDevice** is the handle to the device to query.

• **pMemoryProperties** is a pointer to a `VkPhysicalDeviceMemoryProperties` structure in which the properties are returned.

#### Valid Usage (Implicit)

• **physicalDevice** **must** be a valid `VkPhysicalDevice` handle

• **pMemoryProperties** **must** be a valid pointer to a `VkPhysicalDeviceMemoryProperties` structure

The `VkPhysicalDeviceMemoryProperties` structure is defined as:

```c
typedef struct VkPhysicalDeviceMemoryProperties {
    uint32_t        memoryTypeCount;
    VkMemoryType    memoryTypes[VK_MAX_MEMORY_TYPES];
    uint32_t        memoryHeapCount;
    VkMemoryHeap    memoryHeaps[VK_MAX_MEMORY_HEAPS];
} VkPhysicalDeviceMemoryProperties;
```

• **memoryTypeCount** is the number of valid elements in the `memoryTypes` array.

• **memoryTypes** is an array of `VK_MAX_MEMORY_TYPES` `VkMemoryType` structures describing the
**Memory Types** that *can* be used to access memory allocated from the heaps specified by `memoryHeaps`.

- `memoryHeapCount` is the number of valid elements in the `memoryHeaps` array.
- `memoryHeaps` is an array of `VK_MAX_MEMORY_HEAPS` `VkMemoryHeap` structures describing the memory heaps from which memory *can* be allocated.

The `VkPhysicalDeviceMemoryProperties` structure describes a number of memory heaps as well as a number of memory types that *can* be used to access memory allocated in those heaps. Each heap describes a memory resource of a particular size, and each memory type describes a set of memory properties (e.g., host cached vs uncached) that *can* be used with a given memory heap. Allocations using a particular memory type will consume resources from the heap indicated by that memory type’s heap index. More than one memory type *may* share each heap, and the heaps and memory types provide a mechanism to advertise an accurate size of the physical memory resources while allowing the memory to be used with a variety of different properties.

The number of memory heaps is given by `memoryHeapCount` and is less than or equal to `VK_MAX_MEMORY_HEAPS`. Each heap is described by an element of the `memoryHeaps` array as a `VkMemoryHeap` structure. The number of memory types available across all memory heaps is given by `memoryTypeCount` and is less than or equal to `VK_MAX_MEMORY_TYPES`. Each memory type is described by an element of the `memoryTypes` array as a `VkMemoryType` structure.

At least one heap *must* include `VK_MEMORY_HEAP_DEVICE_LOCAL_BIT` in `VkMemoryHeap::flags`. If there are multiple heaps that all have similar performance characteristics, they *may* all include `VK_MEMORY_HEAP_DEVICE_LOCAL_BIT`. In a unified memory architecture (UMA) system there is often only a single memory heap which is considered to be equally “local” to the host and to the device, and such an implementation *must* advertise the heap as device-local.

Each memory type returned by `vkGetPhysicalDeviceMemoryProperties` *must* have its `propertyFlags` set to one of the following values:

- 0
- `VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT | VK_MEMORY_PROPERTY_HOST_COHERENT_BIT`
- `VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT | VK_MEMORY_PROPERTY_HOST_CACHED_BIT`
- `VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT | VK_MEMORY_PROPERTY_HOST_COHERENT_BIT | VK_MEMORY_PROPERTY_HOST_CACHED_BIT`
- `VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT`
- `VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT | VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT | VK_MEMORY_PROPERTY_HOST_COHERENT_BIT`
- `VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT | VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT | VK_MEMORY_PROPERTY_HOST_CACHED_BIT`
- `VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT | VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT | VK_MEMORY_PROPERTY_HOST_CACHED_BIT`
• VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT |
  VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT |
  VK_MEMORY_PROPERTY_HOST_CACHED_BIT |
  VK_MEMORY_PROPERTY_HOST_COHERENT_BIT

• VK_MEMORYPROPERTY_DEVICE_LOCAL_BIT |
  VK_MEMORYPROPERTY_LAZY_ALLOCATED_BIT

• VK_MEMORYPROPERTY_HOST_VISIBLE_BIT |
  VK_MEMORYPROPERTY_HOST_COHERENT_BIT |
  VK_MEMORYPROPERTY_DEVICE_COHERENT_BIT_AMD

• VK_MEMORYPROPERTY_HOST_VISIBLE_BIT |

  VK_MEMORYPROPERTY_DEVICE_UNCACHED_BIT_AMD

• VK_MEMORYPROPERTY_DEVICE_LOCAL_BIT |
  VK_MEMORYPROPERTY_HOST_VISIBLE_BIT |
  VK_MEMORYPROPERTY_HOST_COHERENT_BIT |
  VK_MEMORYPROPERTY_DEVICE_COHERENT_BIT_AMD |
VK_MEMORY_PROPERTY_HOST_CACHED_BIT |
VK_MEMORY_PROPERTY_HOST_COHERENT_BIT |
VK_MEMORY_PROPERTY_DEVICE_COHERENT_BIT_AMD |
VK_MEMORY_PROPERTY_DEVICE_UNCACHED_BIT_AMD

There must be at least one memory type with both the VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT and VK_MEMORY_PROPERTY_HOST_COHERENT_BIT bits set in its propertyFlags. There must be at least one memory type with the VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT bit set in its propertyFlags. If the deviceCoherentMemory feature is enabled, there must be at least one memory type with the VK_MEMORY_PROPERTY_DEVICE_COHERENT_BIT_AMD bit set in its propertyFlags.

For each pair of elements X and Y returned in memoryTypes, X must be placed at a lower index position than Y if:

- the set of bit flags returned in the propertyFlags member of X is a strict subset of the set of bit flags returned in the propertyFlags member of Y; or

- the propertyFlags members of X and Y are equal, and X belongs to a memory heap with greater performance (as determined in an implementation-specific manner); or

- the propertyFlags members of Y includes VK_MEMORY_PROPERTY_DEVICE_COHERENT_BIT_AMD or VK_MEMORY_PROPERTY_DEVICE_UNCACHED_BIT_AMD and X does not

---

**Note**

There is no ordering requirement between X and Y elements for the case their propertyFlags members are not in a subset relation. That potentially allows more than one possible way to order the same set of memory types. Notice that the list of all allowed memory property flag combinations is written in a valid order. But if instead VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT was before VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT | VK_MEMORY_PROPERTY_HOST_COHERENT_BIT, the list would still be in a valid order.

There may be a performance penalty for using device coherent or uncached device memory types, and using these accidentally is undesirable. In order to avoid this, memory types with these properties always appear at the end of the list; but are subject to the same rules otherwise.

This ordering requirement enables applications to use a simple search loop to select the desired memory type along the lines of:
int32_t findProperties(const VkPhysicalDeviceMemoryProperties* pMemoryProperties,
                       uint32_t memoryTypeBitsRequirement,
                       VkMemoryPropertyFlags requiredProperties) {
    const uint32_t memoryCount = pMemoryProperties->memoryTypeCount;
    for (uint32_t memoryIndex = 0; memoryIndex < memoryCount; ++memoryIndex) {
        const uint32_t memoryTypeBits = (1 << memoryIndex);
        const bool isRequiredMemoryType = memoryTypeBitsRequirement & memoryTypeBits;
        const VkMemoryPropertyFlags properties = pMemoryProperties->memoryTypes[memoryIndex].propertyFlags;
        const bool hasRequiredProperties = (properties & requiredProperties) == requiredProperties;
        if (isRequiredMemoryType && hasRequiredProperties)
            return static_cast<int32_t>(memoryIndex);
    }
    // failed to find memory type
    return -1;
}

// Try to find an optimal memory type, or if it does not exist try fallback memory type
// `device` is the VkDevice
// `image` is the VkImage that requires memory to be bound
// `memoryProperties` properties as returned by vkGetPhysicalDeviceMemoryProperties
// `requiredProperties` are the property flags that must be present
// `optimalProperties` are the property flags that are preferred by the application
VkMemoryRequirements memoryRequirements;
vkGetImageMemoryRequirements(device, image, &memoryRequirements);
int32_t memoryType = findProperties(&memoryProperties, memoryRequirements.memoryTypeBits,
                                      optimalProperties);
if (memoryType == -1) // not found; try fallback properties
    memoryType = findProperties(&memoryProperties, memoryRequirements.memoryTypeBits,
                                 requiredProperties);

To query memory properties, call:

void vkGetPhysicalDeviceMemoryProperties2KHR(
    VkPhysicalDevice physicalDevice,
    VkPhysicalDeviceMemoryProperties2* pMemoryProperties);

• `physicalDevice` is the handle to the device to query.
• `pMemoryProperties` is a pointer to a `VkPhysicalDeviceMemoryProperties2` structure in which the
vkGetPhysicalDeviceMemoryProperties2 behaves similarly to vkGetPhysicalDeviceMemoryProperties, with the ability to return extended information in a pNext chain of output structures.

### Valid Usage (Implicit)

- **physicalDevice** must be a valid VkPhysicalDevice handle
- **pMemoryProperties** must be a valid pointer to a VkPhysicalDeviceMemoryProperties2 structure

The VkPhysicalDeviceMemoryProperties2 structure is defined as:

```c
typedef struct VkPhysicalDeviceMemoryProperties2 {
    VkStructureType sType;
    void* pNext;
    VkPhysicalDeviceMemoryProperties memoryProperties;
} VkPhysicalDeviceMemoryProperties2;
```

or the equivalent

```c
typedef VkPhysicalDeviceMemoryProperties2 VkPhysicalDeviceMemoryProperties2KHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **memoryProperties** is a VkPhysicalDeviceMemoryProperties structure which is populated with the same values as in vkGetPhysicalDeviceMemoryProperties.

### Valid Usage (Implicit)

- **sType** must be VK_STRUCTURE_TYPE_PHYSICAL_DEVICE_MEMORY_PROPERTIES_2
- **pNext** must be NULL or a pointer to a valid instance of VkPhysicalDeviceMemoryBudgetPropertiesEXT
- The sType value of each struct in the pNext chain must be unique

The VkMemoryHeap structure is defined as:

```c
typedef struct VkMemoryHeap {
    VkDeviceSize size;
    VkMemoryHeapFlags flags;
} VkMemoryHeap;
```
- **size** is the total memory size in bytes in the heap.
- **flags** is a bitmask of `VkMemoryHeapFlagBits` specifying attribute flags for the heap.

Bits which **may** be set in `VkMemoryHeap::flags`, indicating attribute flags for the heap, are:

```c
typedef enum VkMemoryHeapFlagBits {
    VK_MEMORY_HEAP_DEVICE_LOCAL_BIT = 0x00000001,
    VK_MEMORY_HEAP_MULTI_INSTANCE_BIT = 0x00000002,
    VK_MEMORY_HEAP_MULTI_INSTANCE_BIT_KHR = VK_MEMORY_HEAP_MULTI_INSTANCE_BIT,
} VkMemoryHeapFlagBits;
```

- **VK_MEMORY_HEAP_DEVICE_LOCAL_BIT** specifies that the heap corresponds to device local memory. Device local memory **may** have different performance characteristics than host local memory, and **may** support different memory property flags.
- **VK_MEMORY_HEAP_MULTI_INSTANCE_BIT** specifies that in a logical device representing more than one physical device, there is a per-physical device instance of the heap memory. By default, an allocation from such a heap will be replicated to each physical device's instance of the heap.

```c
typedef VkFlags VkMemoryHeapFlags;
```

`VkMemoryHeapFlags` is a bitmask type for setting a mask of zero or more `VkMemoryHeapFlagBits`.

The `VkMemoryType` structure is defined as:

```c
typedef struct VkMemoryType {
    VkMemoryPropertyFlags propertyFlags;
    uint32_t heapIndex;
} VkMemoryType;
```

- **heapIndex** describes which memory heap this memory type corresponds to, and **must** be less than `memoryHeapCount` from the `VkPhysicalDeviceMemoryProperties` structure.
- **propertyFlags** is a bitmask of `VkMemoryPropertyFlagBits` of properties for this memory type.

Bits which **may** be set in `VkMemoryType::propertyFlags`, indicating properties of a memory heap, are:
typedef enum VkMemoryPropertyFlagBits {
    VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT = 0x00000001,
    VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT = 0x00000002,
    VK_MEMORY_PROPERTY_HOST_COHERENT_BIT = 0x00000004,
    VK_MEMORY_PROPERTY_HOST_CACHED_BIT = 0x00000008,
    VK_MEMORY_PROPERTY_LAZILY_ALLOCATED_BIT = 0x00000010,
    VK_MEMORY_PROPERTY_DEVICE_COHERENT_BIT_AMD = 0x00000040,
    VK_MEMORY_PROPERTY_DEVICE_UNCACHED_BIT_AMD = 0x00000080,
} VkMemoryPropertyFlagBits;

• **VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT** bit specifies that memory allocated with this type is the most efficient for device access. This property will be set if and only if the memory type belongs to a heap with the **VK_MEMORY_HEAP_DEVICE_LOCAL_BIT** set.

• **VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT** bit specifies that memory allocated with this type can be mapped for host access using `vkMapMemory`.

• **VK_MEMORY_PROPERTY_HOST_COHERENT_BIT** bit specifies that the host cache management commands `vkFlushMappedMemoryRanges` and `vkInvalidateMappedMemoryRanges` are not needed to flush host writes to the device or make device writes visible to the host, respectively.

• **VK_MEMORY_PROPERTY_HOST_CACHED_BIT** bit specifies that memory allocated with this type is cached on the host. Host memory accesses to uncached memory are slower than to cached memory, however uncached memory is always host coherent.

• **VK_MEMORY_PROPERTY_LAZILY_ALLOCATED_BIT** bit specifies that the memory type only allows device access to the memory. Memory types must not have both **VK_MEMORY_PROPERTY_LAZILYALLOCATED_BIT** and **VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT** set. Additionally, the object's backing memory may be provided by the implementation lazily as specified in [Lazily Allocated Memory](chapter10/memory_allocation).  

• **VK_MEMORY_PROPERTY_DEVICE_COHERENT_BIT_AMD** bit specifies that device accesses to allocations of this memory type are automatically made available and visible.

• **VK_MEMORY_PROPERTY_DEVICE_UNCACHED_BIT_AMD** bit specifies that memory allocated with this type is not cached on the device. Uncached device memory is always device coherent.

For any memory allocated with both the **VK_MEMORY_PROPERTY_HOST_COHERENT_BIT** and the **VK_MEMORY_PROPERTY_DEVICE_COHERENT_BIT_AMD**, host or device accesses also perform automatic memory domain transfer operations, such that writes are always automatically available and visible to both host and device memory domains.
Device coherence is a useful property for certain debugging use cases (e.g. crash analysis, where performing separate coherence actions could mean values are not reported correctly). However, device coherent accesses may be slower than equivalent accesses without device coherence, particularly if they are also device uncached. For device uncached memory in particular, repeated accesses to the same or neighbouring memory locations over a short time period (e.g. within a frame) may be slower than it would be for the equivalent cached memory type. As such, it is generally inadvisable to use device coherent or device uncached memory except when really needed.

\[
\text{typedef VkFlags VkMemoryPropertyFlags;}
\]

\text{VkMemoryPropertyFlags} is a bitmask type for setting a mask of zero or more \text{VkMemoryPropertyFlagBits}.

If the \text{VkPhysicalDeviceMemoryBudgetPropertiesEXT} structure is included in the \text{pNext} chain of \text{VkPhysicalDeviceMemoryProperties2}, it is filled with the current memory budgets and usages.

The \text{VkPhysicalDeviceMemoryBudgetPropertiesEXT} structure is defined as:

\[
\text{typedef struct VkPhysicalDeviceMemoryBudgetPropertiesEXT} \{
\text{VkStructureType} \ sType; \\
\text{void}* \ pNext; \\
\text{VkDeviceSize} \ \text{heapBudget}[\text{VK_MAX_MEMORY_HEAPS}]; \\
\text{VkDeviceSize} \ \text{heapUsage}[\text{VK_MAX_MEMORY_HEAPS}];
\} \text{VkPhysicalDeviceMemoryBudgetPropertiesEXT};
\]

- \text{sType} is the type of this structure.
- \text{pNext} is \text{NULL} or a pointer to an extension-specific structure.
- \text{heapBudget} is an array of \text{VK_MAX_MEMORY_HEAPS} \text{VkDeviceSize} values in which memory budgets are returned, with one element for each memory heap. A heap's budget is a rough estimate of how much memory the process can allocate from that heap before allocations may fail or cause performance degradation. The budget includes any currently allocated device memory.
- \text{heapUsage} is an array of \text{VK_MAX_MEMORY_HEAPS} \text{VkDeviceSize} values in which memory usages are returned, with one element for each memory heap. A heap's usage is an estimate of how much memory the process is currently using in that heap.

The values returned in this structure are not invariant. The \text{heapBudget} and \text{heapUsage} values must be zero for array elements greater than or equal to \text{VkPhysicalDeviceMemoryProperties::memoryHeapCount}. The \text{heapBudget} value must be non-zero for array elements less than \text{VkPhysicalDeviceMemoryProperties::memoryHeapCount}. The \text{heapBudget} value must be less than or equal to \text{VkMemoryHeap::size} for each heap.
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_PHYSICAL_DEVICE_MEMORY_BUDGET_PROPERTIES_EXT`

A Vulkan device operates on data in device memory via memory objects that are represented in the API by a `VkDeviceMemory` handle:

```cpp
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkDeviceMemory)
```

To allocate memory objects, call:

```cpp
VkResult vkAllocateMemory(
    VkDevice device, 
    const VkMemoryAllocateInfo* pAllocateInfo, 
    const VkAllocationCallbacks* pAllocator, 
    VkDeviceMemory* pMemory);
```

- **device** is the logical device that owns the memory.
- **pAllocateInfo** is a pointer to a `VkMemoryAllocateInfo` structure describing parameters of the allocation. A successful returned allocation **must** use the requested parameters—no substitution is permitted by the implementation.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pMemory** is a pointer to a `VkDeviceMemory` handle in which information about the allocated memory is returned.

Allocations returned by `vkAllocateMemory` are guaranteed to meet any alignment requirement of the implementation. For example, if an implementation requires 128 byte alignment for images and 64 byte alignment for buffers, the device memory returned through this mechanism would be 128-byte aligned. This ensures that applications **can** correctly suballocate objects of different types (with potentially different alignment requirements) in the same memory object.

When memory is allocated, its contents are undefined.

The maximum number of valid memory allocations that **can** exist simultaneously within a `VkDevice` **may** be restricted by implementation- or platform-dependent limits. If a call to `vkAllocateMemory` would cause the total number of allocations to exceed these limits, such a call will fail and **must** return `VK_ERROR_TOO_MANY_OBJECTS`. The `maxMemoryAllocationCount` feature describes the number of allocations that **can** exist simultaneously before encountering these internal limits.

Some platforms **may** have a limit on the maximum size of a single allocation. For example, certain systems **may** fail to create allocations with a size greater than or equal to 4GB. Such a limit is implementation-dependent, and if such a failure occurs then the error `VK_ERROR_OUT_OF_DEVICE_MEMORY` **must** be returned. This limit is advertised in `VkPhysicalDeviceMaintenance3Properties::maxMemoryAllocationSize`.

---

Chapter 10. Memory Allocation | 467
The cumulative memory size allocated to a heap can be limited by the size of the specified heap. In such cases, allocated memory is tracked on a per-device and per-heap basis. Some platforms allow overallocation into other heaps. The overallocation behavior can be specified through the `VK_AMD_memory_overallocation_behavior` extension.

### Valid Usage

- `pAllocateInfo->allocationSize` must be less than or equal to `VkPhysicalDeviceMemoryProperties::memoryHeaps[memindex].size` where `memindex = VkPhysicalDeviceMemoryProperties::memoryTypes[pAllocateInfo->memoryTypeIndex].heapIndex` as returned by `vkGetPhysicalDeviceMemoryProperties` for the `VkPhysicalDevice` that `device` was created from.

- `pAllocateInfo->memoryTypeIndex` must be less than `VkPhysicalDeviceMemoryProperties::memoryTypeCount` as returned by `vkGetPhysicalDeviceMemoryProperties` for the `VkPhysicalDevice` that `device` was created from.

- If the `deviceCoherentMemory` feature is not enabled, `pAllocateInfo->memoryTypeIndex` must not identify a memory type supporting `VK_MEMORY_PROPERTY_DEVICE_COHERENT_BIT_AMD`.

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle.

- `pAllocateInfo` must be a valid pointer to a valid `VkMemoryAllocateInfo` structure.

- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure.

- `pMemory` must be a valid pointer to a `VkDeviceMemory` handle.

### Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`

- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

- `VK_ERROR_TOO_MANY_OBJECTS`

- `VK_ERROR_INVALID_EXTERNAL_HANDLE`

- `VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS_KHR`

The `VkMemoryAllocateInfo` structure is defined as:
**typedef struct** VkMemoryAllocateInfo {
    VkStructureType sType;
    const void* pNext;
    VkDeviceSize allocationSize;
    uint32_t memoryTypeIndex;
} VkMemoryAllocateInfo;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **allocationSize** is the size of the allocation in bytes
- **memoryTypeIndex** is an index identifying a memory type from the **memoryTypes** array of the **VkPhysicalDeviceMemoryProperties** structure

A **VkMemoryAllocateInfo** structure defines a memory import operation if its **pNext** chain includes one of the following structures:

- **VkImportMemoryWin32HandleInfoKHR** with non-zero **handleType** value
- **VkImportMemoryFdInfoKHR** with a non-zero **handleType** value
- **VkImportMemoryHostPointerInfoEXT** with a non-zero **handleType** value
- **VkImportAndroidHardwareBufferInfoANDROID** with a non-NULL **buffer** value

Importing memory **must** not modify the content of the memory. Implementations **must** ensure that importing memory does not enable the importing Vulkan instance to access any memory or resources in other Vulkan instances other than that corresponding to the memory object imported. Implementations **must** also ensure accessing imported memory which has not been initialized does not allow the importing Vulkan instance to obtain data from the exporting Vulkan instance or vice-versa.

**Note**

How exported and imported memory is isolated is left to the implementation, but applications should be aware that such isolation **may** prevent implementations from placing multiple exportable memory objects in the same physical or virtual page. Hence, applications **should** avoid creating many small external memory objects whenever possible.

When performing a memory import operation, it is the responsibility of the application to ensure the external handles meet all valid usage requirements. However, implementations **must** perform sufficient validation of external handles to ensure that the operation results in a valid memory object which will not cause program termination, device loss, queue stalls, or corruption of other resources when used as allowed according to its allocation parameters. If the external handle provided does not meet these requirements, the implementation **must** fail the memory import operation with the error code **VK_ERROR_INVALID_EXTERNAL_HANDLE**.
Valid Usage

• If the pNext chain includes a VkExportMemoryAllocateInfo structure, and any of the handle types specified in VkExportMemoryAllocateInfo::handleTypes require a dedicated allocation, as reported by vkGetPhysicalDeviceImageFormatProperties2 in VkExternalImageFormatProperties::externalMemoryProperties.externalMemoryFeatures or VkExternalBufferProperties::externalMemoryProperties.externalMemoryFeatures, the pNext chain must include a VkMemoryDedicatedAllocateInfo or VkDedicatedAllocationMemoryAllocateInfoNV structure with either its image or buffer member set to a value other than VK_NULL_HANDLE.

• If the pNext chain includes a VkExportMemoryAllocateInfo structure, it must not include a VkExportMemoryAllocateInfoNV or VkExportMemoryWin32HandleInfoNV structure.

• If the pNext chain includes a VkImportMemoryWin32HandleInfoKHR structure, it must not include a VkImportMemoryWin32HandleInfoNV structure.

• If the parameters define an import operation, the external handle specified was created by the Vulkan API, and the external handle type is VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_FD_BIT_KHR, then the values of allocationSize and memoryTypeIndex must match those specified when the memory object being imported was created.

• If the parameters define an import operation and the external handle specified was created by the Vulkan API, the device mask specified by VkMemoryAllocateFlagsInfo must match that specified when the memory object being imported was allocated.

• If the parameters define an import operation and the external handle is an NT handle or a global share handle created outside of the Vulkan API, the value of memoryTypeIndex must be one of those returned by vkGetMemoryWin32HandlePropertiesKHR.

• If the parameters define an import operation, the external handle was created by the Vulkan API, and the external handle type is VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT_KHR, then the values of allocationSize and memoryTypeIndex must match those specified when the memory object being imported was created.

• If the parameters define an import operation and the external handle type is VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_KMT_BIT, or VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_RESOURCE_BIT, allocationSize must match the size reported in the memory requirements of the image or buffer member of the VkDedicatedAllocationMemoryAllocateInfoNV structure included in the pNext chain.

• If the parameters define an import operation and the external handle type is VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_HEAP_BIT, allocationSize must match the size specified when creating the Direct3D 12 heap from which the external handle was
If the parameters define an import operation and the external handle is a POSIX file descriptor created outside of the Vulkan API, the value of `memoryTypeIndex` must be one of those returned by `vkGetMemoryFdPropertiesKHR`.

If the parameters define an import operation and the external handle is a host pointer, the value of `memoryTypeIndex` must be one of those returned by `vkGetMemoryHostPointerPropertiesEXT`.

If the parameters define an import operation and the external handle is a host pointer, `allocationSize` must be an integer multiple of `VkPhysicalDeviceExternalMemoryHostPropertiesEXT::minImportedHostPointerAlignment`.

If the parameters define an import operation and the external handle is a host pointer, the `pNext` chain must not include a `VkDedicatedAllocationMemoryAllocateInfoNV` structure with either its `image` or `buffer` field set to a value other than `VK_NULL_HANDLE`.

If the parameters define an import operation and the external handle is a host pointer, the `pNext` chain must not include a `VkMemoryDedicatedAllocateInfo` structure with either its `image` or `buffer` field set to a value other than `VK_NULL_HANDLE`.

If the parameters define an import operation and the external handle type is `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID`, `allocationSize` must be the size returned by `vkGetAndroidHardwareBufferPropertiesANDROID` for the Android hardware buffer.

If the parameters define an import operation and the external handle type is `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID`, and the `pNext` chain does not include a `VkMemoryDedicatedAllocateInfo` structure or `VkMemoryDedicatedAllocateInfo::image` is `VK_NULL_HANDLE`, the Android hardware buffer must have a `AHardwareBuffer_Desc::format` of `AHARDWAREBUFFER_FORMAT_BLOB` and a `AHardwareBuffer_Desc::usage` that includes `AHARDWAREBUFFER_USAGE_GPU_DATA_BUFFER`.

If the parameters define an import operation and the external handle type is `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID`, `memoryTypeIndex` must be one of those returned by `vkGetAndroidHardwareBufferPropertiesANDROID` for the Android hardware buffer.

If the parameters do not define an import operation, and the `pNext` chain includes a `VkExportMemoryAllocateInfo` structure with `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID` included in its `handleTypes` member, and the `pNext` chain includes a `VkMemoryDedicatedAllocateInfo` structure with `image` not equal to `VK_NULL_HANDLE`, then `allocationSize` must be 0, otherwise `allocationSize` must be greater than 0.

If the parameters define an import operation, the external handle is an Android hardware buffer, and the `pNext` chain includes a `VkMemoryDedicatedAllocateInfo` with `image` that is not `VK_NULL_HANDLE`, the Android hardware buffer's `AHardwareBuffer::usage` must include at least one of `AHARDWAREBUFFER_USAGE_GPU_COLOR_OUTPUT` or `AHARDWAREBUFFER_USAGE_GPU_SAMPLED_IMAGE`.

If the parameters define an import operation, the external handle is an Android hardware buffer, and the `pNext` chain includes a `VkMemoryDedicatedAllocateInfo` with `image` that is not `VK_NULL_HANDLE`, the format of `image` must be `VK_FORMAT_UNDEFINED` or the format...
returned by `vkGetAndroidHardwareBufferPropertiesANDROID` in `VkAndroidHardwareBufferFormatPropertiesANDROID::format` for the Android hardware buffer.

- If the parameters define an import operation, the external handle is an Android hardware buffer, and the `pNext` chain includes a `VkMemoryDedicatedAllocateInfo` structure with `image` that is not `VK_NULL_HANDLE`, the width, height, and array layer dimensions of `image` and the Android hardware buffer's `AHardwareBuffer_Desc` must be identical.

- If the parameters define an import operation, the external handle is an Android hardware buffer, and the `pNext` chain includes a `VkMemoryDedicatedAllocateInfo` structure with `image` that is not `VK_NULL_HANDLE`, and the Android hardware buffer's `AHardwareBuffer_desc::usage` includes `AHardwareBuffer_USAGE_GPU_MIPMAP_COMPLETE`, the `image` must have a complete mipmap chain.

- If the parameters define an import operation, the external handle is an Android hardware buffer, and the `pNext` chain includes a `VkMemoryDedicatedAllocateInfo` structure with `image` that is not `VK_NULL_HANDLE`, and the Android hardware buffer's `AHardwareBuffer_desc::usage` does not include `AHardwareBuffer_USAGE_GPU_MIPMAP_COMPLETE`, the `image` must have exactly one mipmap level.

- If the parameters define an import operation, the external handle is an Android hardware buffer, and the `pNext` chain includes a `VkMemoryDedicatedAllocateInfo` structure with `image` that is not `VK_NULL_HANDLE`, each bit set in the usage of `image` must be listed in `AHardwareBuffer Usage Equivalence`, and if there is a corresponding `AHardwareBuffer_USAGE` bit listed that bit must be included in the Android hardware buffer's `AHardwareBuffer_Desc::usage`.

- If `VkMemoryOpaqueCaptureAddressAllocateInfo::opaqueCaptureAddress` is not zero, `VkMemoryAllocateFlagsInfo::flags` must include `VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT`.

- If `VkMemoryAllocateFlagsInfo::flags` includes `VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT`, the `bufferDeviceAddressCaptureReplay` feature must be enabled.

- If `VkMemoryAllocateFlagsInfo::flags` includes `VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_BIT`, the `bufferDeviceAddress` feature must be enabled.

- If the `pNext` chain includes a `VkImportMemoryHostPointerInfoEXT` structure, `VkMemoryOpaqueCaptureAddressAllocateInfo::opaqueCaptureAddress` must be zero.

- If the parameters define an import operation, `VkMemoryOpaqueCaptureAddressAllocateInfo::opaqueCaptureAddress` must be zero.
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_MEMORY_ALLOCATE_INFO`

- Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkDedicatedAllocationMemoryAllocateInfoNV`, `VkExportMemoryAllocateInfo`, `VkExportMemoryWin32HandleInfoKHR`, `VkImportAndroidHardwareBufferInfoANDROID`, `VkImportMemoryFdInfoKHR`, `VkImportMemoryHostPointerInfoEXT`, `VkImportMemoryWin32HandleInfoKHR`, `VkImportMemoryWin32HandleInfoNV`, `VkMemoryAllocateFlagsInfo`, `VkMemoryDedicatedAllocateInfo`, `VkMemoryOpaqueCaptureAddressAllocateInfo`, or `VkMemoryPriorityAllocateInfoEXT`

- The `sType` value of each struct in the `pNext` chain must be unique

If the `pNext` chain includes a `VkMemoryDedicatedAllocateInfo` structure, then that structure includes a handle of the sole buffer or image resource that the memory can be bound to.

The `VkMemoryDedicatedAllocateInfo` structure is defined as:

```c
typedef struct VkMemoryDedicatedAllocateInfo {
    VkStructureType    sType;
    const void*        pNext;
    VkImage            image;
    VkBuffer           buffer;
} VkMemoryDedicatedAllocateInfo;
```

or the equivalent

```c
typedef VkMemoryDedicatedAllocateInfo VkMemoryDedicatedAllocateInfoKHR;
```

- `sType` is the type of this structure.

- `pNext` is `NULL` or a pointer to an extension-specific structure.

- `image` is `VK_NULL_HANDLE` or a handle of an image which this memory will be bound to.

- `buffer` is `VK_NULL_HANDLE` or a handle of a buffer which this memory will be bound to.
Valid Usage

- At least one of image and buffer must be VK_NULL_HANDLE

- If image is not VK_NULL_HANDLE and the memory is not an imported Android Hardware Buffer, VkMemoryAllocateInfo::allocationSize must equal the VkMemoryRequirements::size of the image

- If image is not VK_NULL_HANDLE, image must have been created without VK_IMAGE_CREATE_SPARSE_BINDING_BIT set in VkImageCreateInfo::flags

- If buffer is not VK_NULL_HANDLE and the memory is not an imported Android Hardware Buffer, VkMemoryAllocateInfo::allocationSize must equal the VkMemoryRequirements::size of the buffer

- If buffer is not VK_NULL_HANDLE, buffer must have been created without VK_BUFFER_CREATE_SPARSE_BINDING_BIT set in VkBufferCreateInfo::flags

- If image is not VK_NULL_HANDLE and VkMemoryAllocateInfo defines a memory import operation with handle type VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_KMT_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_HEAP_BIT, or VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_RESOURCE_BIT, and the external handle was created by the Vulkan API, then the memory being imported must also be a dedicated image allocation and image must be identical to the image associated with the imported memory

- If buffer is not VK_NULL_HANDLE and VkMemoryAllocateInfo defines a memory import operation with handle type VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_KMT_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_HEAP_BIT, or VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_RESOURCE_BIT, and the external handle was created by the Vulkan API, then the memory being imported must also be a dedicated buffer allocation and buffer must be identical to the buffer associated with the imported memory

- If image is not VK_NULL_HANDLE and VkMemoryAllocateInfo defines a memory import operation with handle type VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_FD_BIT, the memory being imported must also be a dedicated image allocation and image must be identical to the image associated with the imported memory

- If buffer is not VK_NULL_HANDLE and VkMemoryAllocateInfo defines a memory import operation with handle type VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_FD_BIT, the memory being imported must also be a dedicated buffer allocation and buffer must be identical to the buffer associated with the imported memory

- If image is not VK_NULL_HANDLE, image must not have been created with VK_IMAGE_CREATE_DISJOINT_BIT set in VkImageCreateInfo::flags
Valid Usage (Implicit)

- **sType** must be **VK_STRUCTURE_TYPE_MEMORYDEDICATED_ALLOCATE_INFO**
- If **image** is not **VK_NULL_HANDLE**, **image** must be a valid **VkImage** handle
- If **buffer** is not **VK_NULL_HANDLE**, **buffer** must be a valid **VkBuffer** handle
- Both of **buffer**, and **image** that are valid handles of non-ignored parameters **must** have been created, allocated, or retrieved from the same **VkDevice**

If the **pNext** chain includes a **VkDedicatedAllocationMemoryAllocateInfoNV** structure, then that structure includes a handle of the sole buffer or image resource that the memory **can** be bound to.

The **VkDedicatedAllocationMemoryAllocateInfoNV** structure is defined as:

```c
typedef struct VkDedicatedAllocationMemoryAllocateInfoNV {
    VkStructureType    sType;
    const void*        pNext;
    VkImage            image;
    VkBuffer           buffer;
} VkDedicatedAllocationMemoryAllocateInfoNV;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **image** is **VK_NULL_HANDLE** or a handle of an image which this memory will be bound to.
- **buffer** is **VK_NULL_HANDLE** or a handle of a buffer which this memory will be bound to.
**Valid Usage**

- At least one of `image` and `buffer` must be `VK_NULL_HANDLE`
- If `image` is not `VK_NULL_HANDLE`, the image must have been created with `VkDedicatedAllocationImageCreateInfoNV::dedicatedAllocation` equal to `VK_TRUE`
- If `buffer` is not `VK_NULL_HANDLE`, the buffer must have been created with `VkDedicatedAllocationBufferCreateInfoNV::dedicatedAllocation` equal to `VK_TRUE`
- If `image` is not `VK_NULL_HANDLE`, `VkMemoryAllocateInfo::allocationSize` must equal the `VkMemoryRequirements::size` of the image
- If `buffer` is not `VK_NULL_HANDLE`, `VkMemoryAllocateInfo::allocationSize` must equal the `VkMemoryRequirements::size` of the buffer
- If `image` is not `VK_NULL_HANDLE` and `VkMemoryAllocateInfo` defines a memory import operation, the memory being imported must also be a dedicated image allocation and `image` must be identical to the image associated with the imported memory
- If `buffer` is not `VK_NULL_HANDLE` and `VkMemoryAllocateInfo` defines a memory import operation, the memory being imported must also be a dedicated buffer allocation and `buffer` must be identical to the buffer associated with the imported memory

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_DEDICATED_ALLOCATION_MEMORY_ALLOCATE_INFO_NV`
- If `image` is not `VK_NULL_HANDLE`, `image` must be a valid `VkImage` handle
- If `buffer` is not `VK_NULL_HANDLE`, `buffer` must be a valid `VkBuffer` handle
- Both of `buffer`, and `image` that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`

If the `pNext` chain includes a `VkMemoryPriorityAllocateInfoEXT` structure, then that structure includes a priority for the memory.

The `VkMemoryPriorityAllocateInfoEXT` structure is defined as:

```
typedef struct VkMemoryPriorityAllocateInfoEXT {
    VkStructureType sType;
    const void* pNext;
    float priority;
} VkMemoryPriorityAllocateInfoEXT;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `priority` is a floating-point value between 0 and 1, indicating the priority of the allocation relative to other memory allocations. Larger values are higher priority. The granularity of the
priorities is implementation-dependent.

Memory allocations with higher priority **may** be more likely to stay in device-local memory when the system is under memory pressure.

If this structure is not included, it is as if the `priority` value were 0.5.

### Valid Usage

- **priority** must be between 0 and 1, inclusive

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_MEMORY_PRIORITY_ALLOCATE_INFO_EXT`

When allocating memory that **may** be exported to another process or Vulkan instance, add a `VkExportMemoryAllocateInfo` structure to the `pNext` chain of the `VkMemoryAllocateInfo` structure, specifying the handle types that **may** be exported.

The `VkExportMemoryAllocateInfo` structure is defined as:

```c
typedef struct VkExportMemoryAllocateInfo {
    VkStructureType sType;
    const void* pNext;
    VkExternalMemoryHandleTypeFlags handleTypes;
} VkExportMemoryAllocateInfo;
```

or the equivalent

```c
typedef VkExportMemoryAllocateInfo VkExportMemoryAllocateInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **handleTypes** is a bitmask of `VkExternalMemoryHandleTypeFlagBits` specifying one or more memory handle types the application **can** export from the resulting allocation. The application **can** request multiple handle types for the same allocation.

### Valid Usage

- The bits in **handleTypes** **must** be supported and compatible, as reported by `VkExternalImageFormatProperties` or `VkExternalBufferProperties`
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_EXPORT_MEMORY_ALLOCATE_INFO`
- `handleTypes` must be a valid combination of `VkExternalMemoryHandleTypeFlagBits` values

To specify additional attributes of NT handles exported from a memory object, add a `VkExportMemoryWin32HandleInfoKHR` structure to the `pNext` chain of the `VkMemoryAllocateInfo` structure. The `VkExportMemoryWin32HandleInfoKHR` structure is defined as:

```c
typedef struct VkExportMemoryWin32HandleInfoKHR {
    VkStructureType               sType;
    const void*                   pNext;
    const SECURITY_ATTRIBUTES*    pAttributes;
    DWORD                         dwAccess;
    LPCWSTR                       name;
} VkExportMemoryWin32HandleInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `pAttributes` is a pointer to a Windows `SECURITY_ATTRIBUTES` structure specifying security attributes of the handle.
- `dwAccess` is a `DWORD` specifying access rights of the handle.
- `name` is a null-terminated UTF-16 string to associate with the underlying resource referenced by NT handles exported from the created memory.

If `VkExportMemoryAllocateInfo` is not present in the same `pNext` chain, this structure is ignored.

If `VkExportMemoryAllocateInfo` is present in the `pNext` chain of `VkMemoryAllocateInfo` with a Windows `handleType`, but either `VkExportMemoryWin32HandleInfoKHR` is not present in the `pNext` chain, or if it is but `pAttributes` is set to `NULL`, default security descriptor values will be used, and child processes created by the application will not inherit the handle, as described in the MSDN documentation for “Synchronization Object Security and Access Rights”. Further, if the structure is not present, the access rights used depend on the handle type.

For handles of the following types:

- `VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_BIT`
- `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_BIT`

The implementation must ensure the access rights allow read and write access to the memory.

For handles of the following types:

- `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_HEAP_BIT`
- `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_RESOURCE_BIT`
The access rights must be:

**GENERIC_ALL**

1

### Valid Usage

- If `VkExportMemoryAllocateInfo::handleTypes` does not include `VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_BIT`, `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_BIT`, `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_HEAP_BIT`, or `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_RESOURCE_BIT`, a `VkExportMemoryWin32HandleInfoKHR` structure must not be included in the `pNext` chain of `VkMemoryAllocateInfo`.

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_EXPORT_MEMORY_WIN32_HANDLE_INFO_KHR`.
- If `pAttributes` is not NULL, `pAttributes` must be a valid pointer to a valid `SECURITY_ATTRIBUTES` value.

To import memory from a Windows handle, add a `VkImportMemoryWin32HandleInfoKHR` structure to the `pNext` chain of the `VkMemoryAllocateInfo` structure.

The `VkImportMemoryWin32HandleInfoKHR` structure is defined as:

```c
typedef struct VkImportMemoryWin32HandleInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkExternalMemoryHandleTypeFlagBits handleType;
    HANDLE handle;
    LPCWSTR name;
} VkImportMemoryWin32HandleInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `handleType` specifies the type of `handle` or `name`.
- `handle` is the external handle to import, or NULL.
- `name` is a null-terminated UTF-16 string naming the underlying memory resource to import, or NULL.

Importing memory objects from Windows handles does not transfer ownership of the handle to the
Vulkan implementation. For handle types defined as NT handles, the application must release ownership using the CloseHandle system call when the handle is no longer needed.

Applications can import the same underlying memory into multiple instances of Vulkan, into the same instance from which it was exported, and multiple times into a given Vulkan instance. In all cases, each import operation must create a distinct VkDeviceMemory object.

### Valid Usage

- If `handleType` is not 0, it must be supported for import, as reported by VkExternalImageFormatProperties or VkExternalBufferProperties.
- The memory from which `handle` was exported, or the memory named by `name` must have been created on the same underlying physical device as `device`.
- If `handleType` is not 0, it must be defined as an NT handle or a global share handle.
- If `handleType` is not not VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_TEXTURE_BIT, VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_HEAP_BIT, or VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D12_RESOURCE_BIT, `name` must be NULL.
- If `handleType` is not 0 and `handle` is NULL, `name` must name a valid memory resource of the type specified by `handleType`.
- If `handleType` is not 0 and `name` is NULL, `handle` must be a valid handle of the type specified by `handleType`.
- If `handle` is not NULL, `name` must be NULL.
- If `handle` is not NULL, it must obey any requirements listed for `handleType` in external memory handle types compatibility.
- If `name` is not NULL, it must obey any requirements listed for `handleType` in external memory handle types compatibility.

### Valid Usage (Implicit)

- `sType` must be VK_STRUCTURE_TYPE_IMPORT_MEMORY_WIN32_HANDLE_INFO_KHR.
- If `handleType` is not 0, `handleType` must be a valid VkExternalMemoryHandleTypeFlagBits value.

To export a Windows handle representing the underlying resources of a Vulkan device memory object, call:

```c
VkResult vkGetMemoryWin32HandleKHR(
    VkDevice                                    device,
    const VkMemoryGetWin32HandleInfoKHR*        pGetWin32HandleInfo,
    HANDLE*                                     pHandle);
```
• **device** is the logical device that created the device memory being exported.

• **pGetWin32HandleInfo** is a pointer to a `VkMemoryGetWin32HandleInfoKHR` structure containing parameters of the export operation.

• **pHandle** will return the Windows handle representing the underlying resources of the device memory object.

For handle types defined as NT handles, the handles returned by `vkGetMemoryWin32HandleKHR` are owned by the application. To avoid leaking resources, the application **must** release ownership of them using the `CloseHandle` system call when they are no longer needed.

### Valid Usage (Implicit)

- **device** **must** be a valid `VkDevice` handle
- **pGetWin32HandleInfo** **must** be a valid pointer to a valid `VkMemoryGetWin32HandleInfoKHR` structure
- **pHandle** **must** be a valid pointer to a `HANDLE` value

### Return Codes

**Success**
- **VK_SUCCESS**

**Failure**
- **VK_ERROR_TOO_MANY_OBJECTS**
- **VK_ERROR_OUT_OF_HOST_MEMORY**

The `VkMemoryGetWin32HandleInfoKHR` structure is defined as:

```c
typedef struct VkMemoryGetWin32HandleInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkDeviceMemory memory;
    VkExternalMemoryHandleTypeFlagBits handleType;
} VkMemoryGetWin32HandleInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **memory** is the memory object from which the handle will be exported.
- **handleType** is the type of handle requested.

The properties of the handle returned depend on the value of **handleType**. See `VkExternalMemoryHandleTypeFlagBits` for a description of the properties of the defined external
memory handle types.

**Valid Usage**

- `handleType` **must** have been included in `VkExportMemoryAllocateInfo::handleTypes` when memory was created.
- If `handleType` is defined as an NT handle, `vkGetMemoryWin32HandleKHR` **must** be called no more than once for each valid unique combination of `memory` and `handleType`.
- `handleType` **must** be defined as an NT handle or a global share handle.

**Valid Usage (Implicit)**

- `sType` **must** be `VK_STRUCTURE_TYPE_MEMORY_GET_WIN32_HANDLE_INFO_KHR`.
- `pNext` **must** be `NULL`.
- `memory` **must** be a valid `VkDeviceMemory` handle.
- `handleType` **must** be a valid `VkExternalMemoryHandleTypeFlagBits` value.

Windows memory handles compatible with Vulkan **may** also be created by non-Vulkan APIs using methods beyond the scope of this specification. To determine the correct parameters to use when importing such handles, call:

```c
VkResult vkGetMemoryWin32HandlePropertiesKHR(
    VkDevice                             device,  
    VkExternalMemoryHandleTypeFlagBits  handleType,  
    HANDLE                                handle,  
    VkMemoryWin32HandlePropertiesKHR*    pMemoryWin32HandleProperties);
```

- `device` is the logical device that will be importing `handle`.
- `handleType` is the type of the handle `handle`.
- `handle` is the handle which will be imported.
- `pMemoryWin32HandleProperties` will return properties of `handle`.

**Valid Usage**

- `handle` **must** be an external memory handle created outside of the Vulkan API.
- `handleType` **must** not be one of the handle types defined as opaque.
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **handleType** must be a valid `VkExternalMemoryHandleTypeFlagBits` value
- **pMemoryWin32HandleProperties** must be a valid pointer to a `VkMemoryWin32HandlePropertiesKHR` structure

Return Codes

Success

- **VK_SUCCESS**

Failure

- **VK_ERROR_INVALID_EXTERNAL_HANDLE**

The `VkMemoryWin32HandlePropertiesKHR` structure returned is defined as:

```c
typedef struct VkMemoryWin32HandlePropertiesKHR {
    VkStructureType    sType;
    void*              pNext;
    uint32_t           memoryTypeBits;
} VkMemoryWin32HandlePropertiesKHR;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **memoryTypeBits** is a bitmask containing one bit set for every memory type which the specified windows handle can be imported as.

Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_MEMORY_WIN32_HANDLE_PROPERTIES_KHR`
- **pNext** must be **NULL**

To import memory from a POSIX file descriptor handle, add a `VkImportMemoryFdInfoKHR` structure to the **pNext** chain of the `VkMemoryAllocateInfo` structure. The `VkImportMemoryFdInfoKHR` structure is defined as:
typedef struct VkImportMemoryFdInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkExternalMemoryHandleTypeFlagBits handleType;
    int fd;
} VkImportMemoryFdInfoKHR;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `handleType` specifies the handle type of `fd`.
- `fd` is the external handle to import.

Importing memory from a file descriptor transfers ownership of the file descriptor from the application to the Vulkan implementation. The application must not perform any operations on the file descriptor after a successful import.

Applications can import the same underlying memory into multiple instances of Vulkan, into the same instance from which it was exported, and multiple times into a given Vulkan instance. In all cases, each import operation must create a distinct `VkDeviceMemory` object.

**Valid Usage**

- If `handleType` is not 0, it must be supported for import, as reported by `VkExternalImageFormatProperties` or `VkExternalBufferProperties`
- The memory from which `fd` was exported must have been created on the same underlying physical device as `device`
- If `handleType` is not 0, it must be defined as a POSIX file descriptor handle
- If `handleType` is not 0, `fd` must be a valid handle of the type specified by `handleType`
- The memory represented by `fd` must have been created from a physical device and driver that is compatible with `device` and `handleType`, as described in `External memory handle types compatibility`
- `fd` must obey any requirements listed for `handleType` in `external memory handle types compatibility`

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_IMPORT_MEMORY_FD_INFO_KHR`
- If `handleType` is not 0, `handleType` must be a valid `VkExternalMemoryHandleTypeFlagBits` value

To export a POSIX file descriptor representing the underlying resources of a Vulkan device memory object, call:
VkResult vkGetMemoryFdKHR(
    VkDevice device,
    const VkMemoryGetFdInfoKHR* pGetFdInfo,
    int* pFd);

- **device** is the logical device that created the device memory being exported.
- **pGetFdInfo** is a pointer to a VkMemoryGetFdInfoKHR structure containing parameters of the export operation.
- **pFd** will return a file descriptor representing the underlying resources of the device memory object.

Each call to vkGetMemoryFdKHR must create a new file descriptor and transfer ownership of it to the application. To avoid leaking resources, the application must release ownership of the file descriptor using the close system call when it is no longer needed, or by importing a Vulkan memory object from it. Where supported by the operating system, the implementation must set the file descriptor to be closed automatically when an execve system call is made.

### Valid Usage (Implicit)

- **device** must be a valid VkDevice handle
- **pGetFdInfo** must be a valid pointer to a valid VkMemoryGetFdInfoKHR structure
- **pFd** must be a valid pointer to an int value

### Return Codes

**Success**

- VK_SUCCESS

**Failure**

- VK_ERROR_TOO_MANY_OBJECTS
- VK_ERROR_OUT_OF_HOST_MEMORY

The VkMemoryGetFdInfoKHR structure is defined as:

```c
typedef struct VkMemoryGetFdInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkDeviceMemory memory;
    VkExternalMemoryHandleTypeFlagBits handleType;
} VkMemoryGetFdInfoKHR;
```

- **sType** is the type of this structure.
• `pNext` is `NULL` or a pointer to an extension-specific structure.
• `memory` is the memory object from which the handle will be exported.
• `handleType` is the type of handle requested.

The properties of the file descriptor exported depend on the value of `handleType`. See `VkExternalMemoryHandleTypeFlagBits` for a description of the properties of the defined external memory handle types.

*Note*

The size of the exported file may be larger than the size requested by `VkMemoryAllocateInfo::allocationSize`. If `handleType` is `VK_EXTERNAL_MEMORY_HANDLE_TYPE_DMA_BUF_BIT_EXT`, then the application can query the file’s actual size with `lseek(2)`.

**Valid Usage**

• `handleType` must have been included in `VkExportMemoryAllocateInfo::handleTypes` when `memory` was created
• `handleType` must be defined as a POSIX file descriptor handle

**Valid Usage (Implicit)**

• `sType` must be `VK_STRUCTURE_TYPE_MEMORY_GET_FD_INFO_KHR`
• `pNext` must be `NULL`
• `memory` must be a valid `VkDeviceMemory` handle
• `handleType` must be a valid `VkExternalMemoryHandleTypeFlagBits` value

POSIX file descriptor memory handles compatible with Vulkan may also be created by non-Vulkan APIs using methods beyond the scope of this specification. To determine the correct parameters to use when importing such handles, call:

```
VkResult vkGetMemoryFdPropertiesKHR(
  VkDevice                                    device,  
  VkExternalMemoryHandleTypeFlagBits          handleType,  
  int                                          fd,  
  VkMemoryFdPropertiesKHR*                    pMemoryFdProperties);
```

• `device` is the logical device that will be importing `fd`.
• `handleType` is the type of the handle `fd`.
• `fd` is the handle which will be imported.
• `pMemoryFdProperties` is a pointer to a `VkMemoryFdPropertiesKHR` structure in which the
The properties of the handle $fd$ are returned.

**Valid Usage**

- $fd$ must be an external memory handle created outside of the Vulkan API
- `handleType` must not be `VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_FD_BIT_KHR`

**Valid Usage (Implicit)**

- `device` must be a valid `VkDevice` handle
- `handleType` must be a valid `VkExternalMemoryHandleTypeFlagBits` value
- `pMemoryFdProperties` must be a valid pointer to a `VkMemoryFdPropertiesKHR` structure

**Return Codes**

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_INVALID_EXTERNAL_HANDLE`

The `VkMemoryFdPropertiesKHR` structure returned is defined as:

```c
typedef struct VkMemoryFdPropertiesKHR {
    VkStructureType    sType;
    void*              pNext;
    uint32_t           memoryTypeBits;
} VkMemoryFdPropertiesKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `memoryTypeBits` is a bitmask containing one bit set for every memory type which the specified file descriptor can be imported as.

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_MEMORY_FD_PROPERTIES_KHR`
- `pNext` must be `NULL`

To import memory from a host pointer, add a `VkImportMemoryHostPointerInfoEXT` structure to the `pNext` chain of the `VkMemoryAllocateInfo` structure. The `VkImportMemoryHostPointerInfoEXT`
structure is defined as:

```c
typedef struct VkImportMemoryHostPointerInfoEXT {
    VkStructureType sType;
    const void* pNext;
    VkExternalMemoryHandleTypeFlagBits handleType;
    void* pHostPointer;
} VkImportMemoryHostPointerInfoEXT;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `handleType` specifies the handle type.
- `pHostPointer` is the host pointer to import from.

Importing memory from a host pointer shares ownership of the memory between the host and the Vulkan implementation. The application can continue to access the memory through the host pointer but it is the application’s responsibility to synchronize device and non-device access to the underlying memory as defined in Host Access to Device Memory Objects.

Applications can import the same underlying memory into multiple instances of Vulkan and multiple times into a given Vulkan instance. However, implementations may fail to import the same underlying memory multiple times into a given physical device due to platform constraints.

Importing memory from a particular host pointer may not be possible due to additional platform-specific restrictions beyond the scope of this specification in which case the implementation must fail the memory import operation with the error code `VK_ERROR_INVALID_EXTERNAL_HANDLE_KHR`.

The application must ensure that the imported memory range remains valid and accessible for the lifetime of the imported memory object.
Valid Usage

- If `handleType` is not 0, it **must** be supported for import, as reported in `VkExternalMemoryProperties`.

- If `handleType` is not 0, it **must** be `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_ALLOCATION_BIT_EXT` or `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_MAPPED_FOREIGN_MEMORY_BIT_EXT`.

- `pHostPointer` **must** be a pointer aligned to an integer multiple of `VkPhysicalDeviceExternalMemoryHostPropertiesEXT::minImportedHostPointerAlignment`.

- If `handleType` is `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_ALLOCATION_BIT_EXT`, `pHostPointer` **must** be a pointer to `allocationSize` number of bytes of host memory, where `allocationSize` is the member of the `VkMemoryAllocateInfo` structure this structure is chained to.

- If `handleType` is `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_MAPPED_FOREIGN_MEMORY_BIT_EXT`, `pHostPointer` **must** be a pointer to `allocationSize` number of bytes of host mapped foreign memory, where `allocationSize` is the member of the `VkMemoryAllocateInfo` structure this structure is chained to.

Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_IMPORT_MEMORY_HOST_POINTER_INFO_EXT`.

- `handleType` **must** be a valid `VkExternalMemoryHandleTypeFlagBits` value.

To determine the correct parameters to use when importing host pointers, call:

```
#include <vulkan/vulkan.h>

VkResult vkGetMemoryHostPointerPropertiesEXT(
    VkDevice device,        // logical device that will be importing `pHostPointer`
    VkExternalMemoryHandleTypeFlagBits handleType,       // type of the handle `pHostPointer`
    const void* pHostPointer,  // host pointer to import from.
    VkMemoryHostPointerPropertiesEXT* pMemoryHostPointerProperties);   // a pointer to a `VkMemoryHostPointerPropertiesEXT` structure in which the host pointer properties are returned.
```

- `device` is the logical device that will be importing `pHostPointer`.
- `handleType` is the type of the handle `pHostPointer`.
- `pHostPointer` is the host pointer to import from.
- `pMemoryHostPointerProperties` is a pointer to a `VkMemoryHostPointerPropertiesEXT` structure in which the host pointer properties are returned.
Valid Usage

- `handleType` must be `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_ALLOCATION_BIT_EXT` or `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_MAPPED_FOREIGN_MEMORY_BIT_EXT`
- `pHostPointer` must be a pointer aligned to an integer multiple of `VkPhysicalDeviceExternalMemoryHostPropertiesEXT::minImportedHostPointerAlignment`
- If `handleType` is `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_ALLOCATION_BIT_EXT`, `pHostPointer` must be a pointer to host memory
- If `handleType` is `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_MAPPED_FOREIGN_MEMORY_BIT_EXT`, `pHostPointer` must be a pointer to host mapped foreign memory

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `handleType` must be a valid `VkExternalMemoryHandleTypeFlagBits` value
- `pMemoryHostPointerProperties` must be a valid pointer to a `VkMemoryHostPointerPropertiesEXT` structure

Return Codes

Success
- `VK_SUCCESS`

Failure
- `VK_ERROR_INVALID_EXTERNAL_HANDLE`

The `VkMemoryHostPointerPropertiesEXT` structure is defined as:

```c
typedef struct VkMemoryHostPointerPropertiesEXT {
    VkStructureType    sType;
    void*              pNext;
    uint32_t           memoryTypeBits;
} VkMemoryHostPointerPropertiesEXT;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `memoryTypeBits` is a bitmask containing one bit set for every memory type which the specified host pointer can be imported as.

The value returned by `memoryTypeBits` must only include bits that identify memory types which are host visible.
To import memory created outside of the current Vulkan instance from an Android hardware buffer, add a `VkImportAndroidHardwareBufferInfoANDROID` structure to the `pNext` chain of the `VkMemoryAllocateInfo` structure. The `VkImportAndroidHardwareBufferInfoANDROID` structure is defined as:

```c
typedef struct VkImportAndroidHardwareBufferInfoANDROID {
    VkStructureType sType;
    const void* pNext;
    struct AHardwareBuffer* buffer;
} VkImportAndroidHardwareBufferInfoANDROID;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **buffer** is the Android hardware buffer to import.

If the `vkAllocateMemory` command succeeds, the implementation **must** acquire a reference to the imported hardware buffer, which it **must** release when the device memory object is freed. If the command fails, the implementation **must** not retain a reference.

Valid Usage (Implicit)

- **sType** **must** be `VK_STRUCTURE_TYPE_MEMORY_HOST_POINTER_PROPERTIES_EXT`
- **pNext** **must** be `NULL`

Valid Usage

- If `buffer` is not `NULL`, Android hardware buffers **must** be supported for import, as reported by `VkExternalImageFormatProperties` or `VkExternalBufferProperties`
- If `buffer` is not `NULL`, it **must** be a valid Android hardware buffer object with `AHardwareBuffer_Desc::format` and `AHardwareBuffer_Desc::usage` compatible with Vulkan as described in Android Hardware Buffers

Valid Usage (Implicit)

- **sType** **must** be `VK_STRUCTURE_TYPE_IMPORT_ANDROID_HARDWARE_BUFFER_INFO_ANDROID`
- **buffer** **must** be a valid pointer to an `AHardwareBuffer` value

To export an Android hardware buffer representing the underlying resources of a Vulkan device memory object, call:
VkResult vkGetMemoryAndroidHardwareBufferANDROID(
    VkDevice                                    device,
    const VkMemoryGetAndroidHardwareBufferInfoANDROID* pInfo,
    struct AHardwareBuffer**                    pBuffer);

- **device** is the logical device that created the device memory being exported.
- **pInfo** is a pointer to a `VkMemoryGetAndroidHardwareBufferInfoANDROID` structure containing parameters of the export operation.
- **pBuffer** will return an Android hardware buffer representing the underlying resources of the device memory object.

Each call to `vkGetMemoryAndroidHardwareBufferANDROID` must return an Android hardware buffer with a new reference acquired in addition to the reference held by the `VkDeviceMemory`. To avoid leaking resources, the application must release the reference by calling `AHardwareBuffer_release` when it is no longer needed. When called with the same handle in `VkMemoryGetAndroidHardwareBufferInfoANDROID::memory`, `vkGetMemoryAndroidHardwareBufferANDROID` must return the same Android hardware buffer object. If the device memory was created by importing an Android hardware buffer, `vkGetMemoryAndroidHardwareBufferANDROID` must return that same Android hardware buffer object.

### Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pInfo** must be a valid pointer to a valid `VkMemoryGetAndroidHardwareBufferInfoANDROID` structure
- **pBuffer** must be a valid pointer to a valid pointer to an `AHardwareBuffer` value

### Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_TOO_MANY_OBJECTS`
- `VK_ERROR_OUT_OF_HOST_MEMORY`

The `VkMemoryGetAndroidHardwareBufferInfoANDROID` structure is defined as:
typedef struct VkMemoryGetAndroidHardwareBufferInfoANDROID {
    VkStructureType    sType;
    const void*        pNext;
    VkDeviceMemory     memory;
} VkMemoryGetAndroidHardwareBufferInfoANDROID;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• memory is the memory object from which the Android hardware buffer will be exported.

Valid Usage

• VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID must have been included in VkExportMemoryAllocateInfo::handleTypes when memory was created
• If the pNext chain of the VkMemoryAllocateInfo used to allocate memory included a VkMemoryDedicatedAllocateInfo with non-NULL image member, then that image must already be bound to memory

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_MEMORY_GET_ANDROID_HARDWARE_BUFFER_INFO_ANDROID
• pNext must be NULL
• memory must be a valid VkDeviceMemory handle

To determine the memory parameters to use when importing an Android hardware buffer, call:

VkResult vkGetAndroidHardwareBufferPropertiesANDROID(
    VkDevice                                    device,
    const struct AHardwareBuffer*               buffer,
    VkAndroidHardwareBufferPropertiesANDROID*   pProperties);

• device is the logical device that will be importing buffer.
• buffer is the Android hardware buffer which will be imported.
• pProperties is a pointer to a VkAndroidHardwareBufferPropertiesANDROID structure in which the properties of buffer are returned.

Valid Usage

• buffer must be a valid Android hardware buffer object with at least one of the AHARDWAREBUFFER_USAGE_GPU_* flags in its AHardwareBuffer_Desc::usage
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **buffer** must be a valid pointer to a valid `AHardwareBuffer` value
- **pProperties** must be a valid pointer to a `VkAndroidHardwareBufferPropertiesANDROID` structure

Return Codes

**Success**

- **VK_SUCCESS**

**Failure**

- **VK_ERROR_INVALID_EXTERNAL_HANDLE_KHR**

The `VkAndroidHardwareBufferPropertiesANDROID` structure returned is defined as:

```c
typedef struct VkAndroidHardwareBufferPropertiesANDROID {
    VkStructureType    sType;
    void*              pNext;
    VkDeviceSize       allocationSize;
    uint32_t           memoryTypeBits;
} VkAndroidHardwareBufferPropertiesANDROID;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **allocationSize** is the size of the external memory
- **memoryTypeBits** is a bitmask containing one bit set for every memory type which the specified Android hardware buffer can be imported as.

Valid Usage (Implicit)

- **sType** must be **VK_STRUCTURE_TYPE_ANDROID_HARDWARE_BUFFER_PROPERTIES_ANDROID**
- **pNext** must be **NULL** or a pointer to a valid instance of `VkAndroidHardwareBufferFormatPropertiesANDROID`
- The **sType** value of each struct in the **pNext** chain must be unique

To obtain format properties of an Android hardware buffer, include a `VkAndroidHardwareBufferFormatPropertiesANDROID` structure in the **pNext** chain of the `VkAndroidHardwareBufferPropertiesANDROID` structure passed to `vkGetAndroidHardwareBufferPropertiesANDROID`. This structure is defined as:
typedef struct VkAndroidHardwareBufferFormatPropertiesANDROID {
    VkStructureType sType;
    void* pNext;
    VkFormat format;
    uint64_t externalFormat;
    VkFormatFeatureFlags formatFeatures;
    VkComponentMapping samplerYcbcrConversionComponents;
    VkSamplerYcbcrModelConversion suggestedYcbcrModel;
    VkSamplerYcbcrRange suggestedYcbcrRange;
    VkChromaLocation suggestedXChromaOffset;
    VkChromaLocation suggestedYChromaOffset;
} VkAndroidHardwareBufferFormatPropertiesANDROID;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `format` is the Vulkan format corresponding to the Android hardware buffer’s format, or `VK_FORMAT_UNDEFINED` if there is not an equivalent Vulkan format.
- `externalFormat` is an implementation-defined external format identifier for use with `VkExternalFormatANDROID`. It must not be zero.
- `formatFeatures` describes the capabilities of this external format when used with an image bound to memory imported from `buffer`.
- `samplerYcbcrConversionComponents` is the component swizzle that should be used in `VkSamplerYcbcrConversionCreateInfo`.
- `suggestedYcbcrModel` is a suggested color model to use in the `VkSamplerYcbcrConversionCreateInfo`.
- `suggestedYcbcrRange` is a suggested numerical value range to use in `VkSamplerYcbcrConversionCreateInfo`.
- `suggestedXChromaOffset` is a suggested X chroma offset to use in `VkSamplerYcbcrConversionCreateInfo`.
- `suggestedYChromaOffset` is a suggested Y chroma offset to use in `VkSamplerYcbcrConversionCreateInfo`.

If the Android hardware buffer has one of the formats listed in the Format Equivalence table, then `format` must have the equivalent Vulkan format listed in the table. Otherwise, `format` may be `VK_FORMAT_UNDEFINED`, indicating the Android hardware buffer can only be used with an external format.

The `formatFeatures` member must include `VK_FORMAT_FEATURE_SAMPLED_IMAGE_BIT` and at least one of `VK_FORMAT_FEATURE_MIDPOINT_CHROMA_SAMPLES_BIT` or `VK_FORMAT_FEATURE_COSITED_CHROMA_SAMPLES_BIT`, and should include `VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_LINEAR_BIT` and `VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_LINEAR_FILTER_BIT`. 

Chapter 10. Memory Allocation | 495
Note
The formatFeatures member only indicates the features available when using an external-format image created from the Android hardware buffer. Images from Android hardware buffers with a format other than VK_FORMAT_UNDEFINED are subject to the format capabilities obtained from vkGetPhysicalDeviceFormatProperties2, and vkGetPhysicalDeviceImageFormatProperties2 with appropriate parameters. These sets of features are independent of each other, e.g. the external format will support sampler Y’CbCr conversion even if the non-external format does not, and writing to non-external format images is possible but writing to external format images is not.

Android hardware buffers with the same external format must have the same support for VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_LINEAR_BIT, VK_FORMAT_FEATURE_MIDPOINT_CHROMA_SAMPLES_BIT, VK_FORMAT_FEATURE_COSITED_CHROMA_SAMPLES_BIT, VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_LINEAR_FILTER_BIT, VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_SEPARATE_RECONSTRUCTION_FILTER_BIT, and VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_CHROMA_RECONSTRUCTION_EXPLICIT_FORCEABLE_BIT in formatFeatures. Other format features may differ between Android hardware buffers that have the same external format. This allows applications to use the same VkSamplerYcbcrConversion object (and samplers and pipelines created from them) for any Android hardware buffers that have the same external format.

If format is not VK_FORMAT_UNDEFINED, then the value of samplerYcbcrConversionComponents must be valid when used as the components member of VkSamplerYcbcrConversionCreateInfo with that format. If format is VK_FORMAT_UNDEFINED, all members of samplerYcbcrConversionComponents must be VK_COMPONENT_SWIZZLE_IDENTITY.

Implementations may not always be able to determine the color model, numerical range, or chroma offsets of the image contents, so the values in VkAndroidHardwareBufferFormatPropertiesANDROID are only suggestions. Applications should treat these values as sensible defaults to use in the absence of more reliable information obtained through some other means. If the underlying physical device is also usable via OpenGL ES with the GL_OES_EGL_image_external extension, the implementation should suggest values that will produce similar sampled values as would be obtained by sampling the same external image via samplerExternalOES in OpenGL ES using equivalent sampler parameters.

Note
Since GL_OES_EGL_image_external does not require the same sampling and conversion calculations as Vulkan does, achieving identical results between APIs may not be possible on some implementations.

Valid Usage (Implicit)
• sType must be VK_STRUCTURE_TYPE_ANDROID_HARDWARE_BUFFER_FORMAT_PROPERTIES_ANDROID
When allocating memory that may be exported to another process or Vulkan instance, add a `VkExportMemoryAllocateInfoNV` structure to the `pNext` chain of the `VkMemoryAllocateInfo` structure, specifying the handle types that may be exported.

The `VkExportMemoryAllocateInfoNV` structure is defined as:

```c
typedef struct VkExportMemoryAllocateInfoNV {
    VkStructureType sType;
    const void* pNext;
    VkExternalMemoryHandleTypeFlagsNV handleTypes;
} VkExportMemoryAllocateInfoNV;
```

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `handleTypes` is a bitmask of `VkExternalMemoryHandleTypeFlagBitsNV` specifying one or more memory handle types that may be exported. Multiple handle types may be requested for the same allocation as long as they are compatible, as reported by `vkGetPhysicalDeviceExternalImageFormatPropertiesNV`.

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_EXPORT_MEMORY_ALLOCATE_INFO_NV`.
- `handleTypes` must be a valid combination of `VkExternalMemoryHandleTypeFlagBitsNV` values.

When `VkExportMemoryAllocateInfoNV::handleTypes` includes `VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_BIT_NV`, add a `VkExportMemoryWin32HandleInfoNV` structure to the `pNext` chain of the `VkExportMemoryAllocateInfoNV` structure to specify security attributes and access rights for the memory object’s external handle.

The `VkExportMemoryWin32HandleInfoNV` structure is defined as:

```c
typedef struct VkExportMemoryWin32HandleInfoNV {
    VkStructureType sType;
    const void* pNext;
    const SECURITY_ATTRIBUTES* pAttributes;
    DWORD dwAccess;
} VkExportMemoryWin32HandleInfoNV;
```

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `pAttributes` is a pointer to a Windows `SECURITY_ATTRIBUTES` structure specifying security attributes of the handle.
- `dwAccess` is a `DWORD` specifying access rights of the handle.
If this structure is not present, or if `pAttributes` is set to `NULL`, default security descriptor values will be used, and child processes created by the application will not inherit the handle, as described in the MSDN documentation for “Synchronization Object Security and Access Rights”. Further, if the structure is not present, the access rights will be

**DXGI_SHARED_RESOURCE_READ | DXGI_SHARED_RESOURCE_WRITE**

1

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_EXPORT_MEMORY_WIN32_HANDLE_INFO_NV`
- If `pAttributes` is not `NULL`, `pAttributes` must be a valid pointer to a valid `SECURITY_ATTRIBUTES` value

To import memory created on the same physical device but outside of the current Vulkan instance, add a `VkImportMemoryWin32HandleInfoNV` structure to the `pNext` chain of the `VkMemoryAllocateInfo` structure, specifying a handle to and the type of the memory.

The `VkImportMemoryWin32HandleInfoNV` structure is defined as:

```c
typedef struct VkImportMemoryWin32HandleInfoNV {
    VkStructureType                      sType;
    const void*                          pNext;
    VkExternalMemoryHandleTypeFlagsNV    handleType;
    HANDLE                               handle;
} VkImportMemoryWin32HandleInfoNV;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `handleType` is `0` or a `VkExternalMemoryHandleTypeFlagBitsNV` value specifying the type of memory handle in `handle`.
- `handle` is a Windows `HANDLE` referring to the memory.

If `handleType` is `0`, this structure is ignored by consumers of the `VkMemoryAllocateInfo` structure it is chained from.

**Valid Usage**

- `handleType` must not have more than one bit set
- `handle` must be a valid handle to memory, obtained as specified by `handleType`
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_IMPORT_MEMORY_WIN32_HANDLE_INFO_NV`
- `handleType` must be a valid combination of `VkExternalMemoryHandleTypeFlagBitsNV` values

Bits which can be set in `handleType` are:

Possible values of `VkImportMemoryWin32HandleInfoNV::handleType`, specifying the type of an external memory handle, are:

```c
typedef enum VkExternalMemoryHandleTypeFlagBitsNV {
    VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_BIT_NV = 0x00000001,
    VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT_NV = 0x00000002,
    VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_IMAGE_BIT_NV = 0x00000004,
    VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_IMAGE_KMT_BIT_NV = 0x00000008,
} VkExternalMemoryHandleTypeFlagBitsNV;
```

- `VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT_NV` specifies a handle to memory returned by `vkGetMemoryWin32HandleNV`.
- `VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_BIT_NV` specifies a handle to memory returned by `vkGetMemoryWin32HandleNV`, or one duplicated from such a handle using `DuplicateHandle()`.
- `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_IMAGE_BIT_NV` specifies a valid NT handle to memory returned by `IDXGIResource1::CreateSharedHandle`, or a handle duplicated from such a handle using `DuplicateHandle()`.
- `VK_EXTERNAL_MEMORY_HANDLE_TYPE_D3D11_IMAGE_KMT_BIT_NV` specifies a handle to memory returned by `IDXGIResource::GetSharedHandle()`.

```c
typedef VkFlags VkExternalMemoryHandleTypeFlagsNV;
```

`VkExternalMemoryHandleTypeFlagsNV` is a bitmask type for setting a mask of zero or more `VkExternalMemoryHandleTypeFlagBitsNV`.

To retrieve the handle corresponding to a device memory object created with `VkExportMemoryAllocateInfoNV::handleTypes` set to include `VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_KMT_BIT_NV` or `VK_EXTERNAL_MEMORY_HANDLE_TYPE_OPAQUE_WIN32_BIT_NV`, call:

```c
VkResult vkGetMemoryWin32HandleNV(
    VkDevice device, 
    VkDeviceMemory memory, 
    VkExternalMemoryHandleTypeFlagsNV handleType, 
    HANDLE* pHandle);
```
• **device** is the logical device that owns the memory.

• **memory** is the `VkDeviceMemory` object.

• **handleType** is a bitmask of `VkExternalMemoryHandleTypeFlagBitsNV` containing a single bit specifying the type of handle requested.

• **handle** is a pointer to a Windows `HANDLE` in which the handle is returned.

### Valid Usage

- **handleType must** be a flag specified in `VkExportMemoryAllocateInfoNV::handleTypes` when allocating `memory`.

### Valid Usage (Implicit)

- **device must** be a valid `VkDevice` handle
- **memory must** be a valid `VkDeviceMemory` handle
- **handleType must** be a valid combination of `VkExternalMemoryHandleTypeFlagBitsNV` values
- **handleType must** not be 0
- **pHandle must** be a valid pointer to a `HANDLE` value
- **memory must** have been created, allocated, or retrieved from `device`

### Return Codes

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_TOO_MANY_OBJECTS`
- `VK_ERROR_OUT_OF_HOST_MEMORY`

If the `pNext` chain of `VkMemoryAllocateInfo` includes a `VkMemoryAllocateFlagsInfo` structure, then that structure includes flags and a device mask controlling how many instances of the memory will be allocated.

The `VkMemoryAllocateFlagsInfo` structure is defined as:
typedef struct VkMemoryAllocateFlagsInfo {
    VkStructureType sType;
    const void* pNext;
    VkMemoryAllocateFlags flags;
    uint32_t deviceMask;
} VkMemoryAllocateFlagsInfo;

or the equivalent

typedef VkMemoryAllocateFlagsInfo VkMemoryAllocateFlagsInfoKHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **flags** is a bitmask of VkMemoryAllocateFlagBits controlling the allocation.
- **deviceMask** is a mask of physical devices in the logical device, indicating that memory must be allocated on each device in the mask, if VK_MEMORY_ALLOCATE_DEVICE_MASK_BIT is set in **flags**.

If VK_MEMORY_ALLOCATE_DEVICE_MASK_BIT is not set, the number of instances allocated depends on whether VK_MEMORY_HEAP_MULTI_INSTANCE_BIT is set in the memory heap. If VK_MEMORY_HEAP_MULTI_INSTANCE_BIT is set, then memory is allocated for every physical device in the logical device (as if deviceMask has bits set for all device indices). If VK_MEMORY_HEAP_MULTI_INSTANCE_BIT is not set, then a single instance of memory is allocated (as if deviceMask is set to one).

On some implementations, allocations from a multi-instance heap may consume memory on all physical devices even if the deviceMask excludes some devices. If VkPhysicalDeviceGroupProperties::subsetAllocation is VK_TRUE, then memory is only consumed for the devices in the device mask.

**Note**

In practice, most allocations on a multi-instance heap will be allocated across all physical devices. Unicast allocation support is an optional optimization for a minority of allocations.

**Valid Usage**

- If VK_MEMORY_ALLOCATE_DEVICE_MASK_BIT is set, deviceMask must be a valid device mask
- If VK_MEMORY_ALLOCATE_DEVICE_MASK_BIT is set, deviceMask must not be zero
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_MEMORY_ALLOCATE_FLAGS_INFO`
- **flags** must be a valid combination of `VkMemoryAllocateFlagBits` values

Bits which **can** be set in `VkMemoryAllocateFlagsInfo::flags`, controlling device memory allocation, are:

```c
typedef enum VkMemoryAllocateFlagBits {
    VK_MEMORY_ALLOCATE_DEVICE_MASK_BIT = 0x00000001,
    VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_BIT = 0x00000002,
    VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT = 0x00000004,
    VK_MEMORY_ALLOCATE_DEVICE_MASK_BIT_KHR = VK_MEMORY_ALLOCATE_DEVICE_MASK_BIT,
    VK_MEMORY_ALLOCATEDEVICE_ADDRESS_BIT_KHR = VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_BIT,
    VK_MEMORY_ALLOCATEDEVICE_ADDRESS_CAPTURE_REPLAY_BIT_KHR = VK_MEMORY_ALLOCATEDEVICE_ADDRESS_CAPTURE_REPLAY_BIT,
} VkMemoryAllocateFlagBits;
```

or the equivalent

```c
typedef VkMemoryAllocateFlagBits VkMemoryAllocateFlagBitsKHR;
```

- **VK_MEMORY_ALLOCATE_DEVICE_MASK_BIT** specifies that memory will be allocated for the devices in `VkMemoryAllocateFlagsInfo::deviceMask`.
- **VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_BIT** specifies that the memory **can** be attached to a buffer object created with the `VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT` bit set in `usage`, and that the memory handle **can** be used to retrieve an opaque address via `vkGetDeviceMemoryOpaqueCaptureAddress`.
- **VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT** specifies that the memory’s address **can** be saved and reused on a subsequent run (e.g. for trace capture and replay), see `VkBufferOpaqueCaptureAddressCreateInfo` for more detail.

```c
typedef VkFlags VkMemoryAllocateFlags;
```

or the equivalent

```c
typedef VkMemoryAllocateFlags VkMemoryAllocateFlagsKHR;
```

`VkMemoryAllocateFlags` is a bitmask type for setting a mask of zero or more `VkMemoryAllocateFlagBits`.

To request a specific device address for a memory allocation, add a `VkMemoryOpaqueCaptureAddressAllocateInfo` structure to the `pNext` chain of the
The `VkMemoryOpaqueCaptureAddressAllocateInfo` structure is defined as:

```c
typedef struct VkMemoryOpaqueCaptureAddressAllocateInfo {
    VkStructureType sType;
    const void* pNext;
    uint64_t opaqueCaptureAddress;
} VkMemoryOpaqueCaptureAddressAllocateInfo;
```

or the equivalent

```c
typedef VkMemoryOpaqueCaptureAddressAllocateInfo
VkMemoryOpaqueCaptureAddressAllocateInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `opaqueCaptureAddress` is the opaque capture address requested for the memory allocation.

If `opaqueCaptureAddress` is zero, no specific address is requested.

If `opaqueCaptureAddress` is not zero, it **should** be an address retrieved from `vkGetDeviceMemoryOpaqueCaptureAddress` on an identically created memory allocation on the same implementation.

**Note**

In most cases, it is expected that a non-zero `opaqueAddress` is an address retrieved from `vkGetDeviceMemoryOpaqueCaptureAddress` on an identically created memory allocation. If this is not the case, it likely that `VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS` errors will occur.

This is, however, not a strict requirement because trace capture/replay tools may need to adjust memory allocation parameters for imported memory.

If this structure is not present, it is as if `opaqueCaptureAddress` is zero.

**Valid Usage (Implicit)**

- `sType` **must** be `VK_STRUCTURE_TYPE_MEMORY_OPAQUE_CAPTURE_ADDRESS_ALLOCATE_INFO`

To free a memory object, call:
void vkFreeMemory(
  VkDevice device,  
  VkDeviceMemory memory,  
  const VkAllocationCallbacks* pAllocator);

- **device** is the logical device that owns the memory.
- **memory** is the **VkDeviceMemory** object to be freed.
- **pAllocator** controls host memory allocation as described in the **Memory Allocation** chapter.

Before freeing a memory object, an application **must** ensure the memory object is no longer in use by the device—for example by command buffers in the *pending state*. Memory **can** be freed whilst still bound to resources, but those resources **must** not be used afterwards. If there are still any bound images or buffers, the memory **may** not be immediately released by the implementation, but **must** be released by the time all bound images and buffers have been destroyed. Once memory is released, it is returned to the heap from which it was allocated.

How memory objects are bound to Images and Buffers is described in detail in the **Resource Memory Association** section.

If a memory object is mapped at the time it is freed, it is implicitly unmapped.

**Note**

As described below, host writes are not implicitly flushed when the memory object is unmapped, but the implementation **must** guarantee that writes that have not been flushed do not affect any other memory.

---

**Valid Usage**

- All submitted commands that refer to **memory** (via images or buffers) **must** have completed execution

---

**Valid Usage (Implicit)**

- **device** **must** be a valid **VkDevice** handle
- If **memory** is not **VK_NULL_HANDLE**, **memory** **must** be a valid **VkDeviceMemory** handle
- If **pAllocator** is not **NULL**, **pAllocator** **must** be a valid pointer to a valid **VkAllocationCallbacks** structure
- If **memory** is a valid handle, it **must** have been created, allocated, or retrieved from **device**

---

**Host Synchronization**

- Host access to **memory** **must** be externally synchronized
10.2.1. Host Access to Device Memory Objects

Memory objects created with `vkAllocateMemory` are not directly host accessible.

Memory objects created with the memory property `VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT` are considered mappable. Memory objects must be mappable in order to be successfully mapped on the host.

To retrieve a host virtual address pointer to a region of a mappable memory object, call:

```
VkResult vkMapMemory(
    VkDevice                                    device,  
    VkDeviceMemory                              memory,  
    VkDeviceSize                                offset,  
    VkDeviceSize                                size,   
    VkMemoryMapFlags                            flags,  
    void**                                      ppData);
```

- `device` is the logical device that owns the memory.
- `memory` is the `VkDeviceMemory` object to be mapped.
- `offset` is a zero-based byte offset from the beginning of the memory object.
- `size` is the size of the memory range to map, or `VK_WHOLE_SIZE` to map from `offset` to the end of the allocation.
- `flags` is reserved for future use.
- `pData` is a pointer to a `void *` variable in which is returned a host-accessible pointer to the beginning of the mapped range. This pointer minus `offset` must be aligned to at least `VkPhysicalDeviceLimits::minMemoryMapAlignment`.

After a successful call to `vkMapMemory` the memory object `memory` is considered to be currently host mapped.

**Note**

It is an application error to call `vkMapMemory` on a memory object that is already host mapped.

**Note**

`vkMapMemory` will fail if the implementation is unable to allocate an appropriately sized contiguous virtual address range, e.g. due to virtual address space fragmentation or platform limits. In such cases, `vkMapMemory` must return `VK_ERROR_MEMORY_MAP_FAILED`. The application can improve the likelihood of success by reducing the size of the mapped range and/or removing unneeded mappings using `vkUnmapMemory`.

`vkMapMemory` does not check whether the device memory is currently in use before returning the host-accessible pointer. The application must guarantee that any previously submitted command
that writes to this range has completed before the host reads from or writes to that range, and that any previously submitted command that reads from that range has completed before the host writes to that region (see here for details on fulfilling such a guarantee). If the device memory was allocated without the `VK_MEMORY_PROPERTY_HOST_COHERENT_BIT` set, these guarantees must be made for an extended range: the application must round down the start of the range to the nearest multiple of `VkPhysicalDeviceLimits::nonCoherentAtomSize`, and round the end of the range up to the nearest multiple of `VkPhysicalDeviceLimits::nonCoherentAtomSize`.

While a range of device memory is host mapped, the application is responsible for synchronizing both device and host access to that memory range.

Note

It is important for the application developer to become meticulously familiar with all of the mechanisms described in the chapter on Synchronization and Cache Control as they are crucial to maintaining memory access ordering.

Valid Usage

- memory must not be currently host mapped
- offset must be less than the size of memory
- If size is not equal to `VK_WHOLE_SIZE`, size must be greater than 0
- If size is not equal to `VK_WHOLE_SIZE`, size must be less than or equal to the size of the memory minus offset
- memory must have been created with a memory type that reports `VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT`
- memory must not have been allocated with multiple instances

Valid Usage (Implicit)

- device must be a valid `VkDevice` handle
- memory must be a valid `VkDeviceMemory` handle
- flags must be 0
- ppData must be a valid pointer to a pointer value
- memory must have been created, allocated, or retrieved from device

Host Synchronization

- Host access to memory must be externally synchronized
Return Codes

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_MEMORY_MAP_FAILED

```c
typedef VkFlags VkMemoryMapFlags;
```

**VkMemoryMapFlags** is a bitmask type for setting a mask, but is currently reserved for future use.

Two commands are provided to enable applications to work with non-coherent memory allocations: `vkFlushMappedMemoryRanges` and `vkInvalidateMappedMemoryRanges`.

**Note**
If the memory object was created with the `VK_MEMORY_PROPERTY_HOST_COHERENT_BIT` set, `vkFlushMappedMemoryRanges` and `vkInvalidateMappedMemoryRanges` are unnecessary and may have a performance cost. However, availability and visibility operations still need to be managed on the device. See the description of host access types for more information.

**Note**
While memory objects imported from a handle type of `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_ALLOCATION_BIT_EXT` or `VK_EXTERNAL_MEMORY_HANDLE_TYPE_HOST_MAPPED_FOREIGN_MEMORY_BIT_EXT` are inherently mapped to host address space, they are not considered to be host mapped device memory unless they are explicitly host mapped using `vkMapMemory`. That means flushing or invalidating host caches with respect to host accesses performed on such memory through the original host pointer specified at import time is the responsibility of the application and must be performed with appropriate synchronization primitives provided by the platform which are outside the scope of Vulkan. `vkFlushMappedMemoryRanges` and `vkInvalidateMappedMemoryRanges`, however, can still be used on such memory objects to synchronize host accesses performed through the host pointer of the host mapped device memory range returned by `vkMapMemory`.

To flush ranges of non-coherent memory from the host caches, call:
VkResult vkFlushMappedMemoryRanges(
    VkDevice device,
    uint32_t memoryRangeCount,
    const VkMappedMemoryRange* pMemoryRanges);

- `device` is the logical device that owns the memory ranges.
- `memoryRangeCount` is the length of the `pMemoryRanges` array.
- `pMemoryRanges` is a pointer to an array of `VkMappedMemoryRange` structures describing the memory ranges to flush.

`vkFlushMappedMemoryRanges` guarantees that host writes to the memory ranges described by `pMemoryRanges` are made available to the host memory domain, such that they can be made available to the device memory domain via memory domain operations using the `VK_ACCESS_HOST_WRITE_BIT` access type.

Within each range described by `pMemoryRanges`, each set of `nonCoherentAtomSize` bytes in that range is flushed if any byte in that set has been written by the host since it was first host mapped, or the last time it was flushed. If `pMemoryRanges` includes sets of `nonCoherentAtomSize` bytes where no bytes have been written by the host, those bytes must not be flushed.

Unmapping non-coherent memory does not implicitly flush the host mapped memory, and host writes that have not been flushed may not ever be visible to the device. However, implementations must ensure that writes that have not been flushed do not become visible to any other memory.

Note
The above guarantee avoids a potential memory corruption in scenarios where host writes to a mapped memory object have not been flushed before the memory is unmapped (or freed), and the virtual address range is subsequently reused for a different mapping (or memory allocation).

Valid Usage (Implicit)
- `device` must be a valid `VkDevice` handle
- `pMemoryRanges` must be a valid pointer to an array of `memoryRangeCount` valid `VkMappedMemoryRange` structures
- `memoryRangeCount` must be greater than 0
Return Codes

Success
- VK_SUCCESS

Failure
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

To invalidate ranges of non-coherent memory from the host caches, call:

```c
VkResult vkInvalidateMappedMemoryRanges(
    VkDevice device,                        // device
    uint32_t memoryRangeCount,              // memoryRangeCount
    const VkMappedMemoryRange* pMemoryRanges);  // pMemoryRanges
```

- `device` is the logical device that owns the memory ranges.
- `memoryRangeCount` is the length of the `pMemoryRanges` array.
- `pMemoryRanges` is a pointer to an array of `VkMappedMemoryRange` structures describing the memory ranges to invalidate.

`vkInvalidateMappedMemoryRanges` guarantees that device writes to the memory ranges described by `pMemoryRanges`, which have been made available to the host memory domain using the `VK_ACCESS_HOST_WRITE_BIT` and `VK_ACCESS_HOST_READ_BIT` access types, are made visible to the host. If a range of non-coherent memory is written by the host and then invalidated without first being flushed, its contents are undefined.

Within each range described by `pMemoryRanges`, each set of `nonCoherentAtomSize` bytes in that range is invalidated if any byte in that set has been written by the device since it was first host mapped, or the last time it was invalidated.

**Note**
Mapping non-coherent memory does not implicitly invalidate that memory.

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pMemoryRanges` must be a valid pointer to an array of `memoryRangeCount` valid `VkMappedMemoryRange` structures
- `memoryRangeCount` must be greater than 0
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

The `VkMappedMemoryRange` structure is defined as:

typedef struct VkMappedMemoryRange {
    VkStructureType sType;
    const void* pNext;
    VkDeviceMemory memory;
    VkDeviceSize offset;
    VkDeviceSize size;
} VkMappedMemoryRange;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `memory` is the memory object to which this range belongs.
- `offset` is the zero-based byte offset from the beginning of the memory object.
- `size` is either the size of range, or `VK_WHOLE_SIZE` to affect the range from `offset` to the end of the current mapping of the allocation.

Valid Usage

- `memory` must be currently host mapped
- If `size` is not equal to `VK_WHOLE_SIZE`, `offset` and `size` must specify a range contained within the currently mapped range of `memory`
- If `size` is equal to `VK_WHOLE_SIZE`, `offset` must be within the currently mapped range of `memory`
- If `size` is equal to `VK_WHOLE_SIZE`, the end of the current mapping of `memory` must be a multiple of `VkPhysicalDeviceLimits::nonCoherentAtomSize` bytes from the beginning of the memory object
- `offset` must be a multiple of `VkPhysicalDeviceLimits::nonCoherentAtomSize`
- If `size` is not equal to `VK_WHOLE_SIZE`, `size` must either be a multiple of `VkPhysicalDeviceLimits::nonCoherentAtomSize`, or `offset` plus `size` must equal the size of `memory`
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_MAPPED_MEMORY_RANGE`
- **pNext** must be `NULL`
- **memory** must be a valid `VkDeviceMemory` handle

To unmapped a memory object once host access to it is no longer needed by the application, call:

```c
void vkUnmapMemory(
    VkDevice device,        // device is the logical device that owns the memory.
    VkDeviceMemory memory); // memory is the memory object to be unmapped.
```

Valid Usage

- **memory** must be currently host mapped

Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **memory** must be a valid `VkDeviceMemory` handle
- **memory** must have been created, allocated, or retrieved from `device`

Host Synchronization

- Host access to **memory** must be externally synchronized

10.2.2. Lazily Allocated Memory

If the memory object is allocated from a heap with the `VK_MEMORY_PROPERTY_LAZILY_ALLOCATED_BIT` bit set, that object’s backing memory may be provided by the implementation lazily. The actual committed size of the memory may initially be as small as zero (or as large as the requested size), and monotonically increases as additional memory is needed.

A memory type with this flag set is only allowed to be bound to a `VkImage` whose usage flags include `VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT`. 
**Note**

Using lazily allocated memory objects for framebuffer attachments that are not needed once a render pass instance has completed may allow some implementations to never allocate memory for such attachments.

To determine the amount of lazily-allocated memory that is currently committed for a memory object, call:

```c
void vkGetDeviceMemoryCommitment(
  VkDevice device,
  VkDeviceMemory memory,
  VkDeviceSize* pCommittedMemoryInBytes);
```

- `device` is the logical device that owns the memory.
- `memory` is the memory object being queried.
- `pCommittedMemoryInBytes` is a pointer to a `VkDeviceSize` value in which the number of bytes currently committed is returned, on success.

The implementation may update the commitment at any time, and the value returned by this query may be out of date.

The implementation guarantees to allocate any committed memory from the heapIndex indicated by the memory type that the memory object was created with.

### Valid Usage

- `memory` must have been created with a memory type that reports `VK_MEMORY_PROPERTY_LAZILY_ALLOCATED_BIT`

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `memory` must be a valid `VkDeviceMemory` handle
- `pCommittedMemoryInBytes` must be a valid pointer to a `VkDeviceSize` value
- `memory` must have been created, allocated, or retrieved from `device`

### 10.2.3. External Memory Handle Types

**Android Hardware Buffer**

Android’s NDK defines `AHardwareBuffer` objects, which represent device memory that is shareable across processes and that can be accessed by a variety of media APIs and the hardware used to implement them. These Android hardware buffer objects may be imported into `VkDeviceMemory`
objects for access via Vulkan, or exported from Vulkan. An VkImage or VkBuffer can be bound to the imported or exported VkDeviceMemory object if it is created with VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID.

To remove an unnecessary compile-time dependency, an incomplete type definition of AHardwareBuffer is provided in the Vulkan headers:

```
struct AHardwareBuffer;
```

The actual AHardwareBuffer type is defined in Android NDK headers.

**Note**

The NDK format, usage, and size/dimensions of an AHardwareBuffer object can be obtained with the AHardwareBuffer_describe function. While Android hardware buffers can be imported to or exported from Vulkan without using that function, valid usage and implementation behavior is defined in terms of the AHardwareBuffer_Desc properties it returns.

Android hardware buffer objects are reference-counted using Android NDK functions outside of the scope of this specification. A VkDeviceMemory imported from an Android hardware buffer or that can be exported to an Android hardware buffer must acquire a reference to its AHardwareBuffer object, and must release this reference when the device memory is freed. During the host execution of a Vulkan command that has an Android hardware buffer as a parameter (including indirect parameters via pNext chains), the application must not decrement the Android hardware buffer's reference count to zero.

Android hardware buffers can be mapped and unmapped for CPU access using the NDK functions. These lock and unlock APIs are considered to acquire and release ownership of the Android hardware buffer, and applications must follow the rules described in External Resource Sharing to transfer ownership between the Vulkan instance and these native APIs.

Android hardware buffers can be shared with external APIs and Vulkan instances on the same device, and also with foreign devices. When transferring ownership of the Android hardware buffer, the external and foreign special queue families described in Queue Family Ownership Transfer are not identical. All APIs which produce or consume Android hardware buffers are considered to use foreign devices, except OpenGL ES contexts and Vulkan logical devices that have matching device and driver UUIDs. Implementations may treat a transfer to or from the foreign queue family as if it were a transfer to or from the external queue family when the Android hardware buffer's usage only permits it to be used on the same physical device.

**Android Hardware Buffer Optimal Usages**

Vulkan buffer and image usage flags do not correspond exactly to Android hardware buffer usage flags. When allocating Android hardware buffers with non-Vulkan APIs, if any AHARDWAREBUFFER_USAGE_GPU_* usage bits are included, by default the allocator must allocate the memory in such a way that it supports Vulkan usages and creation flags in the usage equivalence table which do not have Android hardware buffer equivalents.
An `VkAndroidHardwareBufferUsageANDROID` structure can be included in the `pNext` chain of a `VkImageFormatProperties2` instance passed to `vkGetPhysicalDeviceImageFormatProperties2` to obtain optimal Android hardware buffer usage flags for specific Vulkan resource creation parameters. Some usage flags returned by these commands are **required** based on the input parameters, but additional vendor-specific usage flags (**AHARDWAREBUFFER_USAGE_VENDOR_**) may also be returned. Any Android hardware buffer allocated with these vendor-specific usage flags and imported to Vulkan **must** only be bound to resources created with parameters that are a subset of the parameters used to obtain the Android hardware buffer usage, since the memory **may** have been allocated in a way incompatible with other parameters. If an Android hardware buffer is successfully allocated with additional non-vendor-specific usage flags in addition to the recommended usage, it **must** support being used in the same ways as an Android hardware buffer allocated with only the recommended usage, and also in ways indicated by the additional usage.

**Android Hardware Buffer External Formats**

Android hardware buffers **may** represent images using implementation-specific formats, layouts, color models, etc., which do not have Vulkan equivalents. Such **external formats** are commonly used by external image sources such as video decoders or cameras. Vulkan **can** import Android hardware buffers that have external formats, but since the image contents are in an undiscoverable and possibly proprietary representation, images with external formats **must** only be used as sampled images, **must** only be sampled with a sampler that has Y’C₆C₇C₈R conversion enabled, and **must** have optimal tiling.

Images that will be backed by an Android hardware buffer **can** use an external format by setting `VkImageCreateInfo::format` to `VK_FORMAT_UNDEFINED` and including a `VkExternalFormatANDROID` structure in the `pNext` chain. Images **can** be created with an external format even if the Android hardware buffer has a format which has an **equivalent Vulkan format** to enable consistent handling of images from sources that might use either category of format. However, all images created with an external format are subject to the valid usage requirements associated with external formats, even if the Android hardware buffer's format has a Vulkan equivalent. The external format of an Android hardware buffer **can** be obtained by passing a `VkAndroidHardwareBufferFormatPropertiesANDROID` structure to `vkGetAndroidHardwareBufferPropertiesANDROID`.

**Android Hardware Buffer Image Resources**

Android hardware buffers have intrinsic width, height, format, and usage properties, so Vulkan images bound to memory imported from an Android hardware buffer **must** use dedicated allocations: `VkMemoryDedicatedRequirements::requiresDedicatedAllocation` **must** be `VK_TRUE` for images created with `VkExternalMemoryImageCreateInfo::handleTypes` that includes `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID`. When creating an image that will be bound to an imported Android hardware buffer, the image creation parameters **must** be equivalent to the AHardwareBuffer properties as described by the valid usage of `VkMemoryAllocateInfo`. Similarly, device memory allocated for a dedicated image **must** not be exported to an Android hardware buffer until it has been bound to that image, and the implementation **must** return an Android hardware buffer with properties derived from the image:

- The `width` and `height` members of `AHardwareBuffer_Desc` **must** be the same as the `width` and `height` members of `VkImageCreateInfo::extent`, respectively.
• The `layers` member of `AHardwareBuffer_Desc` **must** be the same as the `arrayLayers` member of `VkImageCreateInfo`.

• The `format` member of `AHardwareBuffer_Desc` **must** be equivalent to `VkImageCreateInfo::format` as defined by `AHardwareBuffer Format Equivalence`.

• The `usage` member of `AHardwareBuffer_Desc` **must** include bits corresponding to bits included in `VkImageCreateInfo::usage` and `VkImageCreateInfo::flags` where such a correspondence exists according to `AHardwareBuffer Usage Equivalence`. It **may** also include additional usage bits, including vendor-specific usages. Presence of vendor usage bits **may** make the Android hardware buffer only usable in ways indicated by the image creation parameters, even when used outside Vulkan, in a similar way that allocating the Android hardware buffer with usage returned in `VkAndroidHardwareBufferUsageANDROID` does.

Implementations **may** support fewer combinations of image creation parameters for images with Android hardware buffer external handle type than for non-external images. Support for a given set of parameters **can** be determined by passing `VkExternalImageFormatProperties` to `vkGetPhysicalDeviceImageFormatProperties2` with `handleType` set to `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID`. Any Android hardware buffer successfully allocated outside Vulkan with usage that includes `AHARDWAREBUFFER_USAGE_GPU_*` **must** be supported when using equivalent Vulkan image parameters. If a given choice of image parameters are supported for import, they **can** also be used to create an image and memory that will be exported to an Android hardware buffer.

<td>VK_IMAGE_CREATE_EXTENDED_USAGE_BIT</td>
</tr>
</tbody>
</table>

1. **Vulkan does not differentiate between** AHWARDBUFFE_UR_USAGE_GPU_FRAMEBUFFER³ **and** AHWARDBUFFE_UR_USAGE_GPU_FRAMEBUFFER³ **: they both behave as** VK_FORMAT_R8G8B8A8_UNORM. **After an external entity writes to a** AHWARDBUFFE_UR_USAGE_GPU_FRAMEBUFFER³ **Android hardware buffer, the values read by Vulkan from the X/A channel are undefined. To emulate the traditional behavior of the X channel during sampling or blending, applications should use** VK_COMPONENT_SWIZZLE_ONE **in image view component mappings and** VK_BLEND_FACTOR_ONE **in color blend factors. There is no way to avoid copying these undefined values when copying from such an image to another image or buffer.**

2. **The** AHWARDBUFFE_UR_USAGE_GPU_MIPMAP_COMPLETE **flag does not correspond to a Vulkan image usage or creation flag. Instead, its presence indicates that the Android hardware buffer contains a complete mipmap chain, and its absence indicates that the Android hardware buffer contains only a single mip level.**

3. **Only image usages valid for the format are valid. It would be invalid to take a Android Hardware Buffer with a format of** AHWARDBUFFE_UR_USAGE_GPU_FRAMEBUFFER³ **that has a** AHWARDBUFFE_UR_USAGE_GPU_FRAMEBUFFER³ **usage and try to create an image with** VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT.**

**Note**
When using VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT with Android hardware buffer images, applications should use VkImageFormatListCreateInfo to inform the implementation which view formats will be used with the image. For some common sets of format, this allows some implementations to provide significantly better performance when accessing the image via Vulkan.

**Android Hardware Buffer Buffer Resources**

Android hardware buffers with a format of AHWARDBUFFE_UR_USAGE_GPU_DATA_BUFFER can be used as the backing store for VkBuffer objects. Such Android hardware buffers have a size in bytes specified by their width, height and layers are both 1.

Unlike images, buffer resources backed by Android hardware buffers do not require dedicated allocations.
Exported `AHardwareBuffer` objects that do not have dedicated images must have a format of `AHARDWAREBUFFER_FORMAT_BLOB`, usage must include `AHARDWAREBUFFER_USAGE_GPU_DATA_BUFFER`, width must equal the device memory allocation size, and height and layers must be 1.

### 10.2.4. Peer Memory Features

*Peer memory* is memory that is allocated for a given physical device and then bound to a resource and accessed by a different physical device, in a logical device that represents multiple physical devices. Some ways of reading and writing peer memory may not be supported by a device.

To determine how peer memory can be accessed, call:

```c
void vkGetDeviceGroupPeerMemoryFeaturesKHR(
    VkDevice                                    device,
    uint32_t                                    heapIndex,
    uint32_t                                    localDeviceIndex,
    uint32_t                                    remoteDeviceIndex,
    VkPeerMemoryFeatureFlags*                   pPeerMemoryFeatures);
```

- `device` is the logical device that owns the memory.
- `heapIndex` is the index of the memory heap from which the memory is allocated.
- `localDeviceIndex` is the device index of the physical device that performs the memory access.
- `remoteDeviceIndex` is the device index of the physical device that the memory is allocated for.
- `pPeerMemoryFeatures` is a pointer to a `VkPeerMemoryFeatureFlags` bitmask indicating which types of memory accesses are supported for the combination of heap, local, and remote devices.

### Valid Usage

- `heapIndex` must be less than `memoryHeapCount`
- `localDeviceIndex` must be a valid device index
- `remoteDeviceIndex` must be a valid device index
- `localDeviceIndex` must not equal `remoteDeviceIndex`

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pPeerMemoryFeatures` must be a valid pointer to a `VkPeerMemoryFeatureFlags` value

Bits which may be set in the value returned for `vkGetDeviceGroupPeerMemoryFeatures`::`pPeerMemoryFeatures`, indicating the supported peer memory features, are:
typedef enum VkPeerMemoryFeatureFlagBits {
    VK_PEER_MEMORY_FEATURE_COPY_SRC_BIT = 0x00000001,
    VK_PEER_MEMORY_FEATURE_COPY_DST_BIT = 0x00000002,
    VK_PEER_MEMORY_FEATURE_GENERIC_SRC_BIT = 0x00000004,
    VK_PEER_MEMORY_FEATURE_GENERIC_DST_BIT = 0x00000008,
    VK_PEER_MEMORY_FEATURE_COPY_SRC_BIT_KHR = VK_PEER_MEMORY_FEATURE_COPY_SRC_BIT,
    VK_PEER_MEMORY_FEATURE_COPY_DST_BIT_KHR = VK_PEER_MEMORY_FEATURE_COPY_DST_BIT,
    VK_PEER_MEMORY_FEATURE_GENERIC_SRC_BIT_KHR = VK_PEER_MEMORY_FEATURE_GENERIC_SRC_BIT,
    VK_PEER_MEMORY_FEATURE_GENERIC_DST_BIT_KHR = VK_PEER_MEMORY_FEATURE_GENERIC_DST_BIT,
} VkPeerMemoryFeatureFlagBits;

or the equivalent

typedef VkPeerMemoryFeatureFlagBits VkPeerMemoryFeatureFlagBitsKHR;

- **VK_PEER_MEMORY_FEATURE_COPY_SRC_BIT** specifies that the memory can be accessed as the source of a `vkCmdCopyBuffer`, `vkCmdCopyImage`, `vkCmdCopyBufferToImage`, or `vkCmdCopyImageToBuffer` command.

- **VK_PEER_MEMORY_FEATURE_COPY_DST_BIT** specifies that the memory can be accessed as the destination of a `vkCmdCopyBuffer`, `vkCmdCopyImage`, `vkCmdCopyBufferToImage`, or `vkCmdCopyImageToBuffer` command.

- **VK_PEER_MEMORY_FEATURE_GENERIC_SRC_BIT** specifies that the memory can be read as any memory access type.

- **VK_PEER_MEMORY_FEATURE_GENERIC_DST_BIT** specifies that the memory can be written as any memory access type. Shader atomics are considered to be writes.

> Note

The peer memory features of a memory heap also apply to any accesses that may be performed during image layout transitions.

**VK_PEER_MEMORY_FEATURE_COPY_DST_BIT** must be supported for all host local heaps and for at least one device local heap.

If a device does not support a peer memory feature, it is still valid to use a resource that includes both local and peer memory bindings with the corresponding access type as long as only the local bindings are actually accessed. For example, an application doing split-frame rendering would use framebuffer attachments that include both local and peer memory bindings, but would scissor the rendering to only update local memory.

typedef VkFlags VkPeerMemoryFeatureFlags;

or the equivalent

518 | Chapter 10. Memory Allocation
typedef VkPeerMemoryFeatureFlags VkPeerMemoryFeatureFlagsKHR;

VkPeerMemoryFeatureFlags is a bitmask type for setting a mask of zero or more VkPeerMemoryFeatureFlagBits.

To query a 64-bit opaque capture address value from a memory object, call:

```c
uint64_t vkGetDeviceMemoryOpaqueCaptureAddressKHR(
    VkDevice device,
    const VkDeviceMemoryOpaqueCaptureAddressInfo* pInfo);
```

- **device** is the logical device that the memory object was allocated on.
- **pInfo** is a pointer to a VkDeviceMemoryOpaqueCaptureAddressInfo structure specifying the memory object to retrieve an address for.

The 64-bit return value is an opaque address representing the start of pInfo->memory.

If the memory object was allocated with a non-zero value of VkMemoryOpaqueCaptureAddressAllocateInfo::opaqueCaptureAddress, the return value must be the same address.

**Note**
The expected usage for these opaque addresses is only for trace capture/replay tools to store these addresses in a trace and subsequently specify them during replay.

**Valid Usage**

- The bufferDeviceAddress feature must be enabled
- If device was created with multiple physical devices, then the bufferDeviceAddressMultiDevice feature must be enabled

**Valid Usage (Implicit)**

- **device** must be a valid VkDevice handle
- **pInfo** must be a valid pointer to a valid VkDeviceMemoryOpaqueCaptureAddressInfo structure

The VkDeviceMemoryOpaqueCaptureAddressInfo structure is defined as:
typedef struct VkDeviceMemoryOpaqueCaptureAddressInfo {
    VkStructureType    sType;
    const void*        pNext;
    VkDeviceMemory     memory;
} VkDeviceMemoryOpaqueCaptureAddressInfo;

or the equivalent

typedef VkDeviceMemoryOpaqueCaptureAddressInfo
VkDeviceMemoryOpaqueCaptureAddressInfoKHR;

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **memory** specifies the memory whose address is being queried.

**Valid Usage**

- **memory** must have been allocated with **VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_BIT**

**Valid Usage (Implicit)**

- **sType** must be **VK_STRUCTURE_TYPE_DEVICE_MEMORY_OPAQUE_CAPTURE_ADDRESS_INFO**
- **pNext** must be **NULL**
- **memory** must be a valid **VkDeviceMemory** handle
Chapter 11. Resource Creation

Vulkan supports two primary resource types: **buffers** and **images**. Resources are views of memory with associated formatting and dimensionality. Buffers are essentially unformatted arrays of bytes whereas images contain format information, can be multidimensional and may have associated metadata.

### 11.1. Buffers

Buffers represent linear arrays of data which are used for various purposes by binding them to a graphics or compute pipeline via descriptor sets or via certain commands, or by directly specifying them as parameters to certain commands.

Buffers are represented by `VkBuffer` handles:

```
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkBuffer)
```

To create buffers, call:

```c
VkResult vkCreateBuffer(
    VkDevice device,
    const VkBufferCreateInfo* pCreateInfo,
    const VkAllocationCallbacks* pAllocator,
    VkBuffer* pBuffer);
```

- **device** is the logical device that creates the buffer object.
- **pCreateInfo** is a pointer to a `VkBufferCreateInfo` structure containing parameters affecting creation of the buffer.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pBuffer** is a pointer to a `VkBuffer` handle in which the resulting buffer object is returned.

**Valid Usage**

- If the **flags** member of **pCreateInfo** includes `VK_BUFFER_CREATE_SPARSE_BINDING_BIT`, creating this `VkBuffer` must not cause the total required sparse memory for all currently valid sparse resources on the device to exceed `VkPhysicalDeviceLimits::sparseAddressSpaceSize`
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pCreateInfo** must be a valid pointer to a valid `VkBufferCreateInfo` structure
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid `VkAllocationCallbacks` structure
- **pBuffer** must be a valid pointer to a `VkBuffer` handle

Return Codes

**Success**
- **VK_SUCCESS**

**Failure**
- **VK_ERROR_OUT_OF_HOST_MEMORY**
- **VK_ERROR_OUT_OF_DEVICE_MEMORY**
- **VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS_KHR**

The `VkBufferCreateInfo` structure is defined as:

```c
typedef struct VkBufferCreateInfo {
    VkStructureType        sType;
    const void*            pNext;
    VkBufferCreateFlags    flags;
    VkDeviceSize           size;
    VkBufferUsageFlags     usage;
    VkSharingMode          sharingMode;
    uint32_t               queueFamilyIndexCount;
    const uint32_t*        pQueueFamilyIndices;
} VkBufferCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkBufferCreateFlagBits` specifying additional parameters of the buffer.
- **size** is the size in bytes of the buffer to be created.
- **usage** is a bitmask of `VkBufferUsageFlagBits` specifying allowed usages of the buffer.
- **sharingMode** is a `VkSharingMode` value specifying the sharing mode of the buffer when it will be accessed by multiple queue families.
- **queueFamilyIndexCount** is the number of entries in the **pQueueFamilyIndices** array.
- **pQueueFamilyIndices** is a list of queue families that will access this buffer (ignored if **sharingMode**
Valid Usage

- **size must** be greater than 0
- If `sharingMode` is `VK_SHARING_MODE_CONCURRENT`, `pQueueFamilyIndices` **must** be a valid pointer to an array of `queueFamilyIndexCount uint32_t` values
- If `sharingMode` is `VK_SHARING_MODE_CONCURRENT`, `queueFamilyIndexCount` **must** be greater than 1
- If `sharingMode` is `VK_SHARING_MODE_CONCURRENT`, each element of `pQueueFamilyIndices` **must** be unique and **must** be less than `pQueueFamilyPropertyCount` returned by either `vkGetPhysicalDeviceQueueFamilyProperties` or `vkGetPhysicalDeviceQueueFamilyProperties2` for the `physicalDevice` that was used to create device
- If the **sparse bindings** feature is not enabled, `flags` **must** not contain `VK_BUFFER_CREATE_SPARSE_BINDING_BIT`
- If the **sparse buffer residency** feature is not enabled, `flags` **must** not contain `VK_BUFFER_CREATE_SPARSE_RESIDENCY_BIT`
- If the **sparse aliased residency** feature is not enabled, `flags` **must** not contain `VK_BUFFER_CREATE_SPARSE_ALIASED_BIT`
- If `flags` contains `VK_BUFFER_CREATE_SPARSE_RESIDENCY_BIT` or `VK_BUFFER_CREATE_SPARSE_ALIASED_BIT`, it **must** also contain `VK_BUFFER_CREATE_SPARSE_BINDING_BIT`
- If the `pNext` chain includes a `VkExternalMemoryBufferCreateInfo` structure, its `handleTypes` member **must** only contain bits that are also in `VkExternalBufferProperties::externalMemoryProperties.compatibleHandleTypes`, as returned by `vkGetPhysicalDeviceExternalBufferProperties` with `pExternalBufferInfo->handleType` equal to any one of the handle types specified in `VkExternalMemoryBufferCreateInfo::handleTypes`
- If the `pNext` chain includes a `VkDedicatedAllocationBufferCreateInfoNV` structure, and the `dedicatedAllocation` member of the chained structure is `VK_TRUE`, then `flags` **must** not include `VK_BUFFER_CREATE_SPARSE_BINDING_BIT`, `VK_BUFFER_CREATE_SPARSE_RESIDENCY_BIT`, or `VK_BUFFER_CREATE_SPARSE_ALIASED_BIT`
- If `VkBufferDeviceAddressCreateInfoEXT::deviceAddress` is not zero, `flags` **must** include `VK_BUFFER_CREATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT`
- If `VkBufferOpaqueCaptureAddressCreateInfo::opaqueCaptureAddress` is not zero, `flags` **must** include `VK_BUFFER_CREATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT`
- If `flags` includes `VK_BUFFER_CREATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT`, the `bufferDeviceAddressCaptureReplay` or `VkPhysicalDeviceBufferDeviceAddressFeaturesEXT::bufferDeviceAddressCaptureReplay` feature **must** be enabled
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_BUFFER_CREATE_INFO`
- Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkBufferDeviceAddressCreateInfoEXT`, `VkBufferOpaqueCaptureAddressCreateInfo`, `VkDedicatedAllocationBufferCreateInfoNV`, or `VkExternalMemoryBufferCreateInfo`
- The `sType` value of each struct in the `pNext` chain must be unique
- `flags` must be a valid combination of `VkBufferCreateFlagBits` values
- `usage` must be a valid combination of `VkBufferUsageFlagBits` values
- `usage` must not be 0
- `sharingMode` must be a valid `VkSharingMode` value

Bits which **can** be set in `VkBufferCreateInfo::usage`, specifying usage behavior of a buffer, are:

```c
typedef enum VkBufferUsageFlagBits {
    VK_BUFFER_USAGE_TRANSFER_SRC_BIT = 0x00000001,
    VK_BUFFER_USAGE_TRANSFER_DST_BIT = 0x00000002,
    VK_BUFFER_USAGE_UNIFORM_TEXEL_BUFFER_BIT = 0x00000004,
    VK_BUFFER_USAGE_STORAGE_TEXEL_BUFFER_BIT = 0x00000008,
    VK_BUFFER_USAGE_UNIFORM_BUFFER_BIT = 0x00000010,
    VK_BUFFER_USAGE_STORAGE_BUFFER_BIT = 0x00000020,
    VK_BUFFER_USAGE_INDEX_BUFFER_BIT = 0x00000040,
    VK_BUFFER_USAGE_VERTEX_BUFFER_BIT = 0x00000080,
    VK_BUFFER_USAGE_INDIRECT_BUFFER_BIT = 0x00000100,
    VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT = 0x00020000,
    VK_BUFFER_USAGE_TRANSFORM_FEEDBACK_BUFFER_BIT_EXT = 0x00000800,
    VK_BUFFER_USAGE_TRANSFORM_FEEDBACK_COUNTER_BUFFER_BIT_EXT = 0x00001000,
    VK_BUFFER_USAGE_CONDITIONAL_RENDERING_BIT_EXT = 0x00000200,
    VK_BUFFER_USAGE_RAY_TRACING_BIT_KHR = 0x00000400,
    VK_BUFFER_USAGE_RAY_TRACING_BIT_NV = VK_BUFFER_USAGE_RAY_TRACING_BIT_KHR,
    VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT_EXT = VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT,
    VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT_KHR = VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT,
} VkBufferUsageFlagBits;
```

- `VK_BUFFER_USAGE_TRANSFER_SRC_BIT` specifies that the buffer **can** be used as the source of a transfer command (see the definition of `VK_PIPELINE_STAGE_TRANSFER_BIT`).
- `VK_BUFFER_USAGE_TRANSFER_DST_BIT` specifies that the buffer **can** be used as the destination of a transfer command.
- `VK_BUFFER_USAGE_UNIFORM_TEXEL_BUFFER_BIT` specifies that the buffer **can** be used to create a `VkBufferView` suitable for occupying a `VkDescriptorSet` slot of type `VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER`.

524 | Chapter 11. Resource Creation
• **VK_BUFFER_USAGE_STORAGE_TEXEL_BUFFER_BIT** specifies that the buffer can be used to create a `VkBufferView` suitable for occupying a `VkDescriptorSet` slot of type `VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER`.

• **VK_BUFFER_USAGE_UNIFORM_BUFFER_BIT** specifies that the buffer can be used in a `VkDescriptorBufferInfo` suitable for occupying a `VkDescriptorSet` slot either of type `VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER` or `VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC`.

• **VK_BUFFER_USAGE_STORAGE_BUFFER_BIT** specifies that the buffer can be used in a `VkDescriptorBufferInfo` suitable for occupying a `VkDescriptorSet` slot either of type `VK_DESCRIPTOR_TYPE_STORAGE_BUFFER` or `VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC`.

• **VK_BUFFER_USAGE_INDEX_BUFFER_BIT** specifies that the buffer is suitable for passing as the `buffer` parameter to `vkCmdBindIndexBuffer`.

• **VK_BUFFER_USAGE_VERTEX_BUFFER_BIT** specifies that the buffer is suitable for passing as an element of the `pBuffers` array to `vkCmdBindVertexBuffers`.

• **VK_BUFFER_USAGE_INDIRECT_BUFFER_BIT** specifies that the buffer is suitable for passing as the `buffer` parameter to `vkCmdDrawIndirect`, `vkCmdDrawIndexedIndirect`, `vkCmdDrawMeshTasksIndirectNV`, `vkCmdDrawMeshTasksIndirectCountNV`, or `vkCmdDispatchIndirect`. It is also suitable for passing as the `buffer` member of `VkIndirectCommandsStreamNV`, or `sequencesCountBuffer` or `sequencesIndexBuffer` or `preprocessedBuffer` member of `VkGeneratedCommandsInfoNV`.

• **VK_BUFFER_USAGE_CONDITIONAL_RENDERING_BIT_EXT** specifies that the buffer is suitable for passing as the `buffer` parameter to `vkCmdBeginConditionalRenderingEXT`.

• **VK_BUFFER_USAGE_TRANSFORM_FEEDBACK_BUFFER_BIT_EXT** specifies that the buffer is suitable for using for binding as a transform feedback buffer with `vkCmdBindTransformFeedbackBuffersEXT`.

• **VK_BUFFER_USAGE_TRANSFORM_FEEDBACK_COUNTER_BUFFER_BIT_EXT** specifies that the buffer is suitable for using as a counter buffer with `vkCmdBeginTransformFeedbackEXT` and `vkCmdEndTransformFeedbackEXT`.

• **VK_BUFFER_USAGE_RAY_TRACING_BIT_KHR** specifies that the buffer is suitable for use in `vkCmdTraceRaysKHR` and `vkCmdBuildAccelerationStructureKHR`.

• **VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT** specifies that the buffer can be used to retrieve a buffer device address via `vkGetBufferDeviceAddress` and use that address to access the buffer's memory from a shader.

```c
typedef VkFlags VkBufferUsageFlags;
```

`VkBufferUsageFlags` is a bitmask type for setting a mask of zero or more `VkBufferUsageFlagBits`.

Bits which can be set in `VkBufferCreateInfo::flags`, specifying additional parameters of a buffer, are:
typedef enum VkBufferCreateFlagBits {
    VK_BUFFER_CREATE_SPARSE_BINDING_BIT = 0x00000001,
    VK_BUFFER_CREATE_SPARSE_RESIDENCY_BIT = 0x00000002,
    VK_BUFFER_CREATE_SPARSE_ALIASED_BIT = 0x00000004,
    VK_BUFFER_CREATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT = 0x00000010,
    VK_BUFFER_CREATEDEVICEADDRESS_CAPTURE_REPLAY_BIT_EXT =
    VK_BUFFER_CREATEDEVICEADDRESS_CAPTURE_REPLAY_BIT_KHR =
    VK_BUFFER_CREATEDEVICEADDRESS_CAPTURE_REPLAY_BIT,
} VkBufferCreateFlagBits;

- **VK_BUFFER_CREATE_SPARSE_BINDING_BIT** specifies that the buffer will be backed using sparse memory binding.

- **VK_BUFFER_CREATE_SPARSE_RESIDENCY_BIT** specifies that the buffer can be partially backed using sparse memory binding. Buffers created with this flag must also be created with the **VK_BUFFER_CREATE_SPARSE_BINDING_BIT** flag.

- **VK_BUFFER_CREATE_SPARSE_ALIASED_BIT** specifies that the buffer will be backed using sparse memory binding with memory ranges that might also simultaneously be backing another buffer (or another portion of the same buffer). Buffers created with this flag must also be created with the **VK_BUFFER_CREATE_SPARSE_BINDING_BIT** flag.

- **VK_BUFFER_CREATEDEVICEADDRESS_CAPTURE_REPLAY_BIT** specifies that the buffer's address can be saved and reused on a subsequent run (e.g. for trace capture and replay), see **VkBufferOpaqueCaptureAddressCreateInfo** for more detail.

See [Sparse Resource Features](#) and [Physical Device Features](#) for details of the sparse memory features supported on a device.

typedef VkFlags VkBufferCreateFlags;

**VkBufferCreateFlags** is a bitmask type for setting a mask of zero or more **VkBufferCreateFlagBits**.

If the **pNext** chain includes a **VkDedicatedAllocationBufferCreateInfoNV** structure, then that structure includes an enable controlling whether the buffer will have a dedicated memory allocation bound to it.

The **VkDedicatedAllocationBufferCreateInfoNV** structure is defined as:

typedef struct VkDedicatedAllocationBufferCreateInfoNV {
    VkStructureType    sType;
    const void*        pNext;
    VkBool32           dedicatedAllocation;
} VkDedicatedAllocationBufferCreateInfoNV;

- **sType** is the type of this structure.

- **pNext** is **NULL** or a pointer to an extension-specific structure.
• `dedicatedAllocation` specifies whether the buffer will have a dedicated allocation bound to it.

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_DEDICATED_ALLOCATION_BUFFER_CREATE_INFO_NV`

To define a set of external memory handle types that **may** be used as backing store for a buffer, add a `VkExternalMemoryBufferCreateInfo` structure to the `pNext` chain of the `VkBufferCreateInfo` structure. The `VkExternalMemoryBufferCreateInfo` structure is defined as:

```c
typedef struct VkExternalMemoryBufferCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkExternalMemoryHandleTypeFlags handleTypes;
} VkExternalMemoryBufferCreateInfo;
```

or the equivalent

```c
typedef VkExternalMemoryBufferCreateInfo VkExternalMemoryBufferCreateInfoKHR;
```

**Note**

A `VkExternalMemoryBufferCreateInfo` structure must be included in the creation parameters for a buffer that will be bound to memory that is either exported or imported.

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **handleTypes** is a bitmask of `VkExternalMemoryHandleTypeFlagBits` specifying one or more external memory handle types.

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_EXTERNAL_MEMORY_BUFFER_CREATE_INFO`
- **handleTypes** must be a valid combination of `VkExternalMemoryHandleTypeFlagBits` values

To request a specific device address for a buffer, add a `VkBufferOpaqueCaptureAddressCreateInfo` structure to the `pNext` chain of the `VkBufferCreateInfo` structure. The `VkBufferOpaqueCaptureAddressCreateInfo` structure is defined as:
typedef struct VkBufferOpaqueCaptureAddressCreateInfo {
    VkStructureType    sType;
    const void*        pNext;
    uint64_t           opaqueCaptureAddress;
} VkBufferOpaqueCaptureAddressCreateInfo;

or the equivalent

typedef VkBufferOpaqueCaptureAddressCreateInfo
VkBufferOpaqueCaptureAddressCreateInfoKHR;

• `sType` is the type of this structure.
• `pNext` is `NULL` or a pointer to an extension-specific structure.
• `opaqueCaptureAddress` is the opaque capture address requested for the buffer.

If `opaqueCaptureAddress` is zero, no specific address is requested.

If `opaqueCaptureAddress` is not zero, then it `should` be an address retrieved from `vkGetBufferOpaqueCaptureAddress` for an identically created buffer on the same implementation.

If this structure is not present, it is as if `opaqueCaptureAddress` is zero.

Apps `should` avoid creating buffers with app-provided addresses and implementation-provided addresses in the same process, to reduce the likelihood of `VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS` errors.

`Note`

The expected usage for this is that a trace capture/replay tool will add the `VK_BUFFER_CREATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT` flag to all buffers that use `VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT`, and during capture will save the queried opaque device addresses in the trace. During replay, the buffers will be created specifying the original address so any address values stored in the trace data will remain valid.

Implementations are expected to separate such buffers in the GPU address space so normal allocations will avoid using these addresses. Apps/tools should avoid mixing app-provided and implementation-provided addresses for buffers created with `VK_BUFFER_CREATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT`, to avoid address space allocation conflicts.

`Valid Usage (Implicit)`

• `sType` `must` be `VK_STRUCTURE_TYPE_BUFFER_OPAQUE_CAPTURE_ADDRESS_CREATE_INFO`

Alternatively, to request a specific device address for a buffer, add a
VkBufferDeviceAddressCreateInfoEXT structure to the pNext chain of the VkBufferCreateInfo structure. The VkBufferDeviceAddressCreateInfoEXT structure is defined as:

```c
typedef struct VkBufferDeviceAddressCreateInfoEXT {
    VkStructureType    sType;
    const void*        pNext;
    VkDeviceAddress    deviceAddress;
} VkBufferDeviceAddressCreateInfoEXT;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **deviceAddress** is the device address requested for the buffer.

If **deviceAddress** is zero, no specific address is requested.

If **deviceAddress** is not zero, then it **must** be an address retrieved from an identically created buffer on the same implementation. The buffer **must** also be bound to an identically created VkDeviceMemory object.

If this structure is not present, it is as if **deviceAddress** is zero.

Apps **should** avoid creating buffers with app-provided addresses and implementation-provided addresses in the same process, to reduce the likelihood of VK_ERROR_INVALID_DEVICE_ADDRESS_EXT errors.

### Valid Usage (Implicit)

- **sType** must be VK_STRUCTURE_TYPE_BUFFER_DEVICE_ADDRESS_CREATE_INFO_EXT

To destroy a buffer, call:

```c
void vkDestroyBuffer(
    VkDevice                      device,
    VkBuffer                      buffer,
    const VkAllocationCallbacks* pAllocator);
```

- **device** is the logical device that destroys the buffer.
- **buffer** is the buffer to destroy.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
Valid Usage

• All submitted commands that refer to buffer, either directly or via a VkBufferView, must have completed execution

• If VkAllocationCallbacks were provided when buffer was created, a compatible set of callbacks must be provided here

• If no VkAllocationCallbacks were provided when buffer was created, pAllocator must be NULL

Valid Usage (Implicit)

• device must be a valid VkDevice handle

• If buffer is not VK_NULL_HANDLE, buffer must be a valid VkBuffer handle

• If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure

• If buffer is a valid handle, it must have been created, allocated, or retrieved from device

Host Synchronization

• Host access to buffer must be externally synchronized

11.2. Buffer Views

A buffer view represents a contiguous range of a buffer and a specific format to be used to interpret the data. Buffer views are used to enable shaders to access buffer contents interpreted as formatted data. In order to create a valid buffer view, the buffer must have been created with at least one of the following usage flags:

• VK_BUFFER_USAGE_UNIFORM_TEXEL_BUFFER_BIT
• VK_BUFFER_USAGE_STORAGE_TEXEL_BUFFER_BIT

Buffer views are represented by VkBufferView handles:

```
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkBufferView)
```

To create a buffer view, call:
VkResult vkCreateBufferView(
    VkDevice                                    device,
    const VkBufferViewCreateInfo*               pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkBufferView*                               pView);

- **device** is the logical device that creates the buffer view.
- **pCreateInfo** is a pointer to a VkBufferViewCreateInfo structure containing parameters to be used to create the buffer.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pView** is a pointer to a VkBufferView handle in which the resulting buffer view object is returned.

**Valid Usage (Implicit)**

- **device** must be a valid VkDevice handle
- **pCreateInfo** must be a valid pointer to a valid VkBufferViewCreateInfo structure
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid VkAllocationCallbacks structure
- **pView** must be a valid pointer to a VkBufferView handle

**Return Codes**

**Success**

- VK_SUCCESS

**Failure**

- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

The VkBufferViewCreateInfo structure is defined as:

```c
typedef struct VkBufferViewCreateInfo {
    VkStructureType            sType;
    const void*                pNext;
    VkBufferViewCreateFlags    flags;
    VkBuffer                   buffer;
    VkFormat                   format;
    VkDeviceSize               offset;
    VkDeviceSize               range;
} VkBufferViewCreateInfo;
```
• **sType** is the type of this structure.
• **pNext** is **NULL** or a pointer to an extension-specific structure.
• **flags** is reserved for future use.
• **buffer** is a VkBuffer on which the view will be created.
• **format** is a VkFormat describing the format of the data elements in the buffer.
• **offset** is an offset in bytes from the base address of the buffer. Accesses to the buffer view from shaders use addressing that is relative to this starting offset.
• **range** is a size in bytes of the buffer view. If **range** is equal to **VK_WHOLE_SIZE**, the range from **offset** to the end of the buffer is used. If **VK_WHOLE_SIZE** is used and the remaining size of the buffer is not a multiple of the texel block size of **format**, the nearest smaller multiple is used.
Valid Usage

- **Offset** must be less than the size of **buffer**
- If **range** is not equal to **VK_WHOLE_SIZE**, **range** must be greater than 0
- If **range** is not equal to **VK_WHOLE_SIZE**, **range** must be an integer multiple of the texel block size of **format**
- If **range** is not equal to **VK_WHOLE_SIZE**, **range** divided by the number of texels per texel block for that format (as defined in the Compatible Formats table), **must** be less than or equal to **VkPhysicalDeviceLimits::maxTexelBufferElements**
- If **range** is not equal to **VK_WHOLE_SIZE**, the sum of **offset** and **range** must be less than or equal to the size of **buffer**
- **Buffer** must have been created with a **usage** value containing at least one of **VK_BUFFER_USAGE_UNIFORM_TEXEL_BUFFER_BIT** or **VK_BUFFER_USAGE_STORAGE_TEXEL_BUFFER_BIT**
- If **buffer** was created with **usage** containing **VK_BUFFER_USAGE_UNIFORM_TEXEL_BUFFER_BIT**, **format** must be supported for uniform texel buffers, as specified by the **VK_FORMAT_FEATURE_UNIFORM_TEXEL_BUFFER_BIT** flag in **VkFormatProperties::bufferFeatures** returned by **vkGetPhysicalDeviceFormatProperties**
- If **buffer** was created with **usage** containing **VK_BUFFER_USAGE_STORAGE_TEXEL_BUFFER_BIT**, **format** must be supported for storage texel buffers, as specified by the **VK_FORMAT_FEATURE_STORAGE_TEXEL_BUFFER_BIT** flag in **VkFormatProperties::bufferFeatures** returned by **vkGetPhysicalDeviceFormatProperties**
- If **buffer** is non-sparse then it **must** be bound completely and contiguously to a single **VkDeviceMemory** object
- If the **texelBufferAlignment** feature is not enabled, **offset** must be a multiple of **VkPhysicalDeviceLimits::minTexelBufferOffsetAlignment**
- If the **texelBufferAlignment** feature is enabled and if **buffer** was created with **usage** containing **VK_BUFFER_USAGE_STORAGE_TEXEL_BUFFER_BIT**, **offset** must be a multiple of the lesser of **VkPhysicalDeviceTexelBufferAlignmentPropertiesEXT::storageTexelBufferOffsetAlignmentBytes** or, if **VkPhysicalDeviceTexelBufferAlignmentPropertiesEXT::storageTexelBufferOffsetSingleTexelAlignment** is **VK_TRUE**, the size of a texel of the requested **format**. If the size of a texel is a multiple of three bytes, then the size of a single component of **format** is used instead
- If the **texelBufferAlignment** feature is enabled and if **buffer** was created with **usage** containing **VK_BUFFER_USAGE_UNIFORM_TEXEL_BUFFER_BIT**, **offset** must be a multiple of the lesser of **VkPhysicalDeviceTexelBufferAlignmentPropertiesEXT::uniformTexelBufferOffsetAlignmentBytes** or, if **VkPhysicalDeviceTexelBufferAlignmentPropertiesEXT::uniformTexelBufferOffsetSingleTexelAlignment** is **VK_TRUE**, the size of a texel of the requested **format**. If the size of a texel is a multiple of three bytes, then the size of a single component of **format** is used instead
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_BUFFER_VIEW_CREATE_INFO`
- `pNext` must be `NULL`
- `flags` must be `0`
- `buffer` must be a valid `VkBuffer` handle
- `format` must be a valid `VkFormat` value

```plaintext
typedef VkFlags VkBufferViewCreateFlags;
```

`VkBufferViewCreateFlags` is a bitmask type for setting a mask, but is currently reserved for future use.

To destroy a buffer view, call:

```c
void vkDestroyBufferView(
    VkDevice device,          // device is the logical device that destroys the buffer view.
    VkBufferView bufferView,  // bufferView is the buffer view to destroy.
    const VkAllocationCallbacks* pAllocator);  // pAllocator controls host memory allocation as described in the Memory Allocation chapter.
```

Valid Usage

- All submitted commands that refer to `bufferView` must have completed execution
- If `VkAllocationCallbacks` were provided when `bufferView` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `bufferView` was created, `pAllocator` must be `NULL`
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle.
- If `bufferView` is not `VK_NULL_HANDLE`, `bufferView` must be a valid `VkBufferView` handle.
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure.
- If `bufferView` is a valid handle, it must have been created, allocated, or retrieved from `device`.

Host Synchronization

- Host access to `bufferView` must be externally synchronized.

11.3. Images

Images represent multidimensional - up to 3 - arrays of data which can be used for various purposes (e.g. attachments, textures), by binding them to a graphics or compute pipeline via descriptor sets, or by directly specifying them as parameters to certain commands.

Images are represented by `VkImage` handles:

```
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkImage)
```

To create images, call:

```c
VkResult vkCreateImage(
    VkDevice device,
    const VkImageCreateInfo* pCreateInfo,
    const VkAllocationCallbacks* pAllocator,
    VkImage* pImage);
```

- **device** is the logical device that creates the image.
- `pCreateInfo` is a pointer to a `VkImageCreateInfo` structure containing parameters to be used to create the image.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
- `pImage` is a pointer to a `VkImage` handle in which the resulting image object is returned.
Valid Usage

• If the flags member of pCreateInfo includes VK_IMAGE_CREATE_SPARSE_BINDING_BIT, creating this VkImage must not cause the total required sparse memory for all currently valid sparse resources on the device to exceed VkPhysicalDeviceLimits::sparseAddressSpaceSize.

Valid Usage (Implicit)

• device must be a valid VkDevice handle
• pCreateInfo must be a valid pointer to a valid VkImageCreateInfo structure
• If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure
• pImage must be a valid pointer to a VkImage handle

Return Codes

Success

• VK_SUCCESS

Failure

• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

The VkImageCreateInfo structure is defined as:

```c
typedef struct VkImageCreateInfo {
    VkStructureType          sType;
    const void*              pNext;
    VkImageCreateFlags       flags;
    VkImageType              imageType;
    VkFormat                 format;
    VkExtent3D               extent;
    uint32_t                 mipLevels;
    uint32_t                 arrayLayers;
    VkSampleCountFlagBits    samples;
    VkImageTiling            tiling;
    VkImageUsageFlags        usage;
    VkSharingMode            sharingMode;
    uint32_t                 queueFamilyIndexCount;
    const uint32_t*          pQueueFamilyIndices;
    VkImageLayout            initialLayout;
} VkImageCreateInfo;
```
- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **flags** is a bitmask of VkImageCreateFlagBits describing additional parameters of the image.
- **imageType** is a VkImageType value specifying the basic dimensionality of the image. Layers in array textures do not count as a dimension for the purposes of the image type.
- **format** is a VkFormat describing the format and type of the texel blocks that will be contained in the image.
- **extent** is a VkExtent3D describing the number of data elements in each dimension of the base level.
- **mipLevels** describes the number of levels of detail available for minified sampling of the image.
- **arrayLayers** is the number of layers in the image.
- **samples** is a VkSampleCountFlagBits specifying the number of samples per texel.
- **tiling** is a VkImageTiling value specifying the tiling arrangement of the texel blocks in memory.
- **usage** is a bitmask of VkImageUsageFlagBits describing the intended usage of the image.
- **sharingMode** is a VkSharingMode value specifying the sharing mode of the image when it will be accessed by multiple queue families.
- **queueFamilyIndexCount** is the number of entries in the pQueueFamilyIndices array.
- **pQueueFamilyIndices** is a list of queue families that will access this image (ignored if sharingMode is not VK_SHARING_MODE_CONCURRENT).
- **initialLayout** is a VkImageLayout value specifying the initial VkImageLayout of all image subresources of the image. See Image Layouts.

Images created with **tiling** equal to VK_IMAGE_TILING_LINEAR have further restrictions on their limits and capabilities compared to images created with **tiling** equal to VK_IMAGE_TILING_OPTIMAL. Creation of images with tiling VK_IMAGE_TILING_LINEAR may not be supported unless other parameters meet all of the constraints:

- **imageType** is VK_IMAGE_TYPE_2D
- **format** is not a depth/stencil format
- **mipLevels** is 1
- **arrayLayers** is 1
- **samples** is VK_SAMPLE_COUNT_1_BIT
- **usage** only includes VK_IMAGE_USAGE_TRANSFER_SRC_BIT and/or VK_IMAGE_USAGE_TRANSFER_DST_BIT

Images created with a **format** from one of those listed in Formats requiring sampler Y’CbCr conversion for VK_IMAGE_ASPECT_COLOR_BIT image views have further restrictions on their limits and capabilities compared to images created with other formats. Creation of images with a format requiring Y’CbCr conversion may not be supported unless other parameters meet all of the constraints:

- **imageType** is VK_IMAGE_TYPE_2D
mipLevels is 1
arrayLayers is 1
samples is VK_SAMPLE_COUNT_1_BIT

Implementations may support additional limits and capabilities beyond those listed above.

To determine the set of valid usage bits for a given format, call vkGetPhysicalDeviceFormatProperties.

If the size of the resultant image would exceed maxResourceSize, then vkCreateImage must fail and returnVK_ERROR_OUT_OF_DEVICE_MEMORY. This failure may occur even when all image creation parameters satisfy their valid usage requirements.

Note
For images created without VK_IMAGE_CREATE_EXTENDED_USAGE_BIT a usage bit is valid if it is supported for the format the image is created with.

For images created with VK_IMAGE_CREATE_EXTENDED_USAGE_BIT a usage bit is valid if it is supported for at least one of the formats a VkImageView created from the image can have (see Image Views for more detail).
**Image Creation Limits**

Valid values for some image creation parameters are limited by a numerical upper bound or by inclusion in a bitset. For example, `VkImageCreateInfo::arrayLayers` is limited by `imageCreateMaxArrayLayers`, defined below; and `VkImageCreateInfo::samples` is limited by `imageCreateSampleCounts`, also defined below.

Several limiting values are defined below, as well as assisting values from which the limiting values are derived. The limiting values are referenced by the relevant valid usage statements of `VkImageCreateInfo`.

- Let `uint64_t imageCreateDrmFormatModifiers[]` be the set of Linux DRM format modifiers that the resultant image may have.
  - If tiling is not `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then `imageCreateDrmFormatModifiers` is empty.
  - If `VkImageCreateInfo::pNext` contains `VkImageDrmFormatModifierExplicitCreateInfoEXT`, then `imageCreateDrmFormatModifiers` contains exactly one modifier, `VkImageDrmFormatModifierExplicitCreateInfoEXT::drmFormatModifier`.
  - If `VkImageCreateInfo::pNext` contains `VkImageDrmFormatModifierListCreateInfoEXT`, then `imageCreateDrmFormatModifiers` contains the entire array `VkImageDrmFormatModifierListCreateInfoEXT::pDrmFormatModifiers`.

- Let `VkBool32 imageCreateMaybeLinear` indicate if the resultant image may be linear.
  - If tiling is `VK_IMAGE_TILING_LINEAR`, then `imageCreateMaybeLinear` is true.
  - If tiling is `VK_IMAGE_TILING_OPTIMAL`, then `imageCreateMaybeLinear` is false.
  - If tiling is `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then `imageCreateMaybeLinear` is true if and only if `imageCreateDrmFormatModifiers` contains `DRM_FORMAT_MOD_LINEAR`.

- Let `VkFormatFeatureFlags imageCreateFormatFeatures` be the set of valid format features available during image creation.
  - If tiling is `VK_IMAGE_TILING_LINEAR`, then `imageCreateFormatFeatures` is the value of `VkImageFormatProperties::linearTilingFeatures` found by calling `vkGetPhysicalDeviceFormatProperties` with parameter `format` equal to `VkImageCreateInfo::format`.
  - If tiling is `VK_IMAGE_TILING_OPTIMAL`, and if the `pNext` chain includes no `VkExternalFormatANDROID` structure with non-zero `externalFormat`, then `imageCreateFormatFeatures` is value of `VkImageFormatProperties::optimalTilingFeatures` found by calling `vkGetPhysicalDeviceFormatProperties` with parameter `format` equal to `VkImageCreateInfo::format`.
  - If tiling is `VK_IMAGE_TILING_OPTIMAL`, and if the `pNext` chain includes a `VkExternalFormatANDROID` structure with non-zero `externalFormat`, then `imageCreateFormatFeatures` is the value of `VkAndroidHardwareBufferFormatPropertiesANDROID::formatFeatures` obtained by `vkGetAndroidHardwareBufferPropertiesANDROID` with a matching `externalFormat`.
If tiling is VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT, then the value of imageCreateFormatFeatures is found by calling vkGetPhysicalDeviceFormatProperties2 with VkImageFormatProperties::format equal to VkImageCreateInfo::format and with VkDrmFormatModifierPropertiesListEXT chained into VkImageFormatProperties2; by collecting all members of the returned array VkDrmFormatModifierPropertiesListEXT::pDrmFormatModifierProperties whose drmFormatModifier belongs to imageCreateDrmFormatModifiers; and by taking the bitwise intersection, over the collected array members, of drmFormatModifierTilingFeatures. (The resultant imageCreateFormatFeatures may be empty).

Let VkImageFormatProperties2 imageCreateImageFormatPropertiesList[] be defined as follows.

- If VkImageCreateInfo::pNext contains no VkExternalFormatANDROID structure with non-zero externalFormat, then imageCreateImageFormatPropertiesList is the list of structures obtained by calling vkGetPhysicalDeviceImageFormatProperties2, possibly multiple times, as follows:
  - The parameters VkPhysicalDeviceImageFormatInfo2::format, imageType, tiling, usage, and flags must be equal to those in VkImageCreateInfo.
  - If VkImageCreateInfo::pNext contains a VkExternalMemoryImageCreateInfo structure whose handleTypes is not 0, then VkPhysicalDeviceImageFormatInfo2 ::pNext must contain a VkPhysicalDeviceExternalImageFormatInfo structure whose handleType is not 0; and vkGetPhysicalDeviceImageFormatProperties2 must be called for each handle type in VkExternalMemoryImageCreateInfo::handleTypes, successively setting VkPhysicalDeviceExternalImageFormatInfo::handleType on each call.
  - If VkImageCreateInfo::pNext contains no VkExternalMemoryImageCreateInfo structure, or contains a structure whose handleTypes is 0, then VkPhysicalDeviceImageFormatInfo2 ::pNext must either contain no VkPhysicalDeviceExternalImageFormatInfo structure, or contain a structure whose handleType is 0.
  - If tiling is VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT, then VkPhysicalDeviceImageFormatInfo2::pNext must contain a VkPhysicalDeviceImageDrmFormatModifierInfoEXT structure where sharingMode is equal to VkImageCreateInfo::sharingMode; and, if sharingMode is VK_SHARING_MODE_CONCURRENT, then queueFamilyIndexCount and pQueueFamilyIndices must be equal to those in VkImageCreateInfo; and, if flags contains VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT, then the VkImageFormatListCreateInfo structure included in the pNext chain of VkPhysicalDeviceImageFormatInfo2 must be equivalent to the one included in the pNext chain of VkImageCreateInfo; and vkGetPhysicalDeviceImageFormatProperties2 must be called for each modifier in imageCreateDrmFormatModifiers, successively setting VkPhysicalDeviceImageDrmFormatModifierInfoEXT::drmFormatModifier on each call.
  - If tiling is not VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT, then VkPhysicalDeviceImageFormatInfo2::pNext must contain no
If any call to `vkGetPhysicalDeviceImageFormatProperties2` returns an error, then `imageCreateImageFormatPropertiesList` is defined to be the empty list.

- If `VkImageCreateInfo::pNext` contains a `VkExternalFormatANDROID` structure with non-zero `externalFormat`, then `imageCreateImageFormatPropertiesList` contains a single element where:
  - `VkImageFormatProperties::maxMipLevels` is $\lceil \log_2(\max(\text{extent.width, extent.height, extent.depth})) \rceil + 1$.
  - `VkImageFormatProperties::maxArrayLayers` is `VkPhysicalDeviceLimits::maxImageArrayLayers`.
  - Each component of `VkImageFormatProperties::maxExtent` is `VkPhysicalDeviceLimits::maxImageDimension2D`.
  - `VkImageFormatProperties::sampleCounts` contains exactly `VK_SAMPLE_COUNT_1_BIT`.

- Let `uint32_t imageCreateMaxMipLevels` be the minimum value of `VkImageFormatProperties::maxMipLevels` in `imageCreateImageFormatPropertiesList`. The value is undefined if `imageCreateImageFormatPropertiesList` is empty.
- Let `uint32_t imageCreateMaxArrayLayers` be the minimum value of `VkImageFormatProperties::maxArrayLayers` in `imageCreateImageFormatPropertiesList`. The value is undefined if `imageCreateImageFormatPropertiesList` is empty.
- Let `VkExtent3D imageCreateMaxExtent` be the component-wise minimum over all `VkImageFormatProperties::maxExtent` values in `imageCreateImageFormatPropertiesList`. The value is undefined if `imageCreateImageFormatPropertiesList` is empty.
- Let `VkSampleCountFlags imageCreateSampleCounts` be the intersection of each `VkImageFormatProperties::sampleCounts` in `imageCreateImageFormatPropertiesList`. The value is undefined if `imageCreateImageFormatPropertiesList` is empty.
Valid Usage

• Each of the following values (as described in Image Creation Limits) must not be undefined: `imageCreateMaxMipLevels`, `imageCreateMaxArrayLayers`, `imageCreateMaxExtent`, and `imageCreateSampleCounts`.

• If `sharingMode` is `VK_SHARING_MODE_CONCURRENT`, `pQueueFamilyIndices` must be a valid pointer to an array of `queueFamilyIndexCount uint32_t` values.

• If `sharingMode` is `VK_SHARING_MODE_CONCURRENT`, `queueFamilyIndexCount` must be greater than 1.

• If `sharingMode` is `VK_SHARING_MODE_CONCURRENT`, each element of `pQueueFamilyIndices` must be unique and must be less than `pQueueFamilyPropertyCount` returned by either `vkGetPhysicalDeviceQueueFamilyProperties` or `vkGetPhysicalDeviceQueueFamilyProperties2` for the `physicalDevice` that was used to create `device`.

• If the `pNext` chain includes a `VkExternalFormatANDROID` structure, and its `externalFormat` member is non-zero, the `format` must be `VK_FORMAT_UNDEFINED`.

• If the `pNext` chain does not include a `VkExternalFormatANDROID` structure, or does and its `externalFormat` member is 0, the `format` must not be `VK_FORMAT_UNDEFINED`.

• `extent.width` must be greater than 0.

• `extent.height` must be greater than 0.

• `extent.depth` must be greater than 0.

• `mipLevels` must be greater than 0.

• `arrayLayers` must be greater than 0.

• If `flags` contains `VK_IMAGE_CREATE_CUBE_COMPATIBLE_BIT`, `imageType` must be `VK_IMAGE_TYPE_2D`.

• If `flags` contains `VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_EXT`, `imageType` must be `VK_IMAGE_TYPE_2D`.

• If `flags` contains `VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT`, `imageType` must be `VK_IMAGE_TYPE_3D`.

• `extent.width` must be less than or equal to `imageCreateMaxExtent.width` (as defined in Image Creation Limits).

• `extent.height` must be less than or equal to `imageCreateMaxExtent.height` (as defined in Image Creation Limits).

• `extent.depth` must be less than or equal to `imageCreateMaxExtent.depth` (as defined in Image Creation Limits).

• If `imageType` is `VK_IMAGE_TYPE_2D` and `flags` contains `VK_IMAGE_CREATE_CUBE_COMPATIBLE_BIT`, `extent.width` and `extent.height` must be equal and `arrayLayers` must be greater than or equal to 6.

• If `imageType` is `VK_IMAGE_TYPE_1D`, both `extent.height` and `extent.depth` must be 1.

• If `imageType` is `VK_IMAGE_TYPE_2D`, `extent.depth` must be 1.

• `mipLevels` must be less than or equal to the number of levels in the complete mipmap.
chain based on extent.width, extent.height, and extent.depth

- **mipLevels** must be less than or equal to `imageCreateMaxMipLevels` (as defined in Image Creation Limits)

- **arrayLayers** must be less than or equal to `imageCreateMaxArrayLayers` (as defined in Image Creation Limits)

- If `imageType` is `VK_IMAGE_TYPE_3D`, `arrayLayers` must be 1

- If `samples` is not `VK_SAMPLE_COUNT_1_BIT`, then `imageType` must be `VK_IMAGE_TYPE_2D`, `flags` must not contain `VK_IMAGE_CREATE_CUBE_COMPATIBLE_BIT`, `mipLevels` must be equal to 1, and `imageCreateMaybeLinear` (as defined in Image Creation Limits) must be false,

- If `samples` is not `VK_SAMPLE_COUNT_1_BIT`, `usage` must not contain `VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_EXT`

- If `usage` includes `VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT`, then bits other than `VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT`, `VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT`, and `VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT` must not be set

- If `usage` includes `VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT`, `VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT`, or `VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT`, `extent.width` must be less than or equal to `VkPhysicalDeviceLimits::maxFramebufferWidth`

- If `usage` includes `VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT`, `VK_IMAGEUSAGE_DEPTH_STENCIL_ATTACHMENT_BIT`, or `VK_IMAGE USAGE_INPUT_ATTACHMENT_BIT`, `extent.height` must be less than or equal to `VkPhysicalDeviceLimits::maxFramebufferHeight`

- If `usage` includes `VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_EXT`, `extent.width` must be less than or equal to `\frac{maxFramebufferWidth}{minFragmentDensityTexelSize.width}`

- If `usage` includes `VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_EXT`, `extent.height` must be less than or equal to `\frac{maxFramebufferHeight}{minFragmentDensityTexelSize.height}`

- If `usage` includes `VK_IMAGEUSAGE_TRANSIENT_ATTACHMENT_BIT`, `usage` must also contain at least one of `VK_IMAGEUSAGE_COLOR_ATTACHMENT_BIT`, `VK_IMAGEUSAGE_DEPTH_STENCIL_ATTACHMENT_BIT`, or `VK_IMAGEUSAGE_INPUT_ATTACHMENT_BIT`

- `samples` must be a bit value that is set in `imageCreateSampleCounts` (as defined in Image Creation Limits)

- If the multisampled storage images feature is not enabled, and `usage` contains `VK_IMAGEUSAGE_STORAGE_BIT`, `samples` must be `VK_SAMPLE_COUNT_1_BIT`

- If the sparse bindings feature is not enabled, `flags` must not contain `VK_IMAGE_CREATE_SPARSE_BINDING_BIT`

- If the sparse aliased residency feature is not enabled, `flags` must not contain `VK_IMAGE_CREATE_SPARSE_ALIASED_BIT`

- If `imageType` is `VK_IMAGE_TYPE_1D`, `flags` must not contain `VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT`

- If the sparse residency for 2D images feature is not enabled, and `imageType` is `VK_IMAGE_TYPE_2D`, `flags` must not contain `VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT`

- If the sparse residency for 3D images feature is not enabled, and `imageType` is...
• If the sparse residency for images with 2 samples feature is not enabled, `imageType` is `VK_IMAGE_TYPE_2D`, and `samples` is `VK_SAMPLE_COUNT_2_BIT`, `flags` must not contain `VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT`.

• If the sparse residency for images with 4 samples feature is not enabled, `imageType` is `VK_IMAGE_TYPE_2D`, and `samples` is `VK_SAMPLE_COUNT_4_BIT`, `flags` must not contain `VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT`.

• If the sparse residency for images with 8 samples feature is not enabled, `imageType` is `VK_IMAGE_TYPE_2D`, and `samples` is `VK_SAMPLE_COUNT_8_BIT`, `flags` must not contain `VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT`.

• If the sparse residency for images with 16 samples feature is not enabled, `imageType` is `VK_IMAGE_TYPE_2D`, and `samples` is `VK_SAMPLE_COUNT_16_BIT`, `flags` must not contain `VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT`.

• If `flags` contains `VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT` or `VK_IMAGE_CREATE_SPARSE_ALIASED_BIT`, it must also contain `VK_IMAGE_CREATE_SPARSE_BINDING_BIT`.

• If any of the bits `VK_IMAGE_CREATE_SPARSE_BINDING_BIT`, `VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT`, or `VK_IMAGE_CREATE_SPARSE_ALIASED_BIT` are set, `VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT` must not also be set.

• If the `pNext` chain includes a `VkExternalMemoryImageCreateInfoNV` structure, it must not contain a `VkExternalMemoryImageCreateInfo` structure.

• If the `pNext` chain includes a `VkExternalMemoryImageCreateInfo` structure, its `handleTypes` member must only contain bits that are also in `VkExternalImageFormatProperties::externalMemoryProperties.compatibleHandleTypes`, as returned by `vkGetPhysicalDeviceImageFormatProperties2` with `format`, `imageType`, `tiling`, `usage`, and `flags` equal to those in this structure, and with a `VkPhysicalDeviceExternalImageFormatInfo` structure included in the `pNext` chain, with a `handleType` equal to any one of the handle types specified in `VkExternalMemoryImageCreateInfo::handleTypes`.

• If the `pNext` chain includes a `VkExternalMemoryImageCreateInfoNV` structure, its `handleTypes` member must only contain bits that are also in `VkExternalImageFormatPropertiesNV::externalMemoryProperties.compatibleHandleTypes`, as returned by `vkGetPhysicalDeviceExternalImageFormatPropertiesNV` with `format`, `imageType`, `tiling`, `usage`, and `flags` equal to those in this structure, and with `externalHandleType` equal to any one of the handle types specified in `VkExternalMemoryImageCreateInfoNV::handleTypes`.

• If the logical device was created with `VkDeviceGroupDeviceCreateInfo::physicalDeviceCount` equal to 1, `flags` must not contain `VK_IMAGE_CREATE_SPLIT_INSTANCE_BIND_REGIONS_BIT`.

• If `flags` contains `VK_IMAGE_CREATE_SPLIT_INSTANCE_BIND_REGIONS_BIT`, then `mipLevels` must be one, `arrayLayers` must be one, `imageType` must be `VK_IMAGE_TYPE_2D`, and `imageCreateMaybeLinear` (as defined in Image Creation Limits) must be false.

• If `flags` contains `VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT`, then `format` must be a block-compressed image format, an ETC compressed image format, or an ASTC compressed image format.
• If flags contains `VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT`, then flags **must** also contain `VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT`.

• `initialLayout` **must** be `VK_IMAGE_LAYOUT_UNDEFINED` or `VK_IMAGE_LAYOUT_PREINITIALIZED`.

• If the `pNext` chain includes a `VkExternalMemoryImageCreateInfo` or `VkExternalMemoryImageCreateInfoNV` structure whose `handleTypes` member is not **0**, `initialLayout` **must** be `VK_IMAGE_LAYOUT_UNDEFINED`.

• If the image format is one of those listed in Formats requiring sampler Y’C_bC_R conversion for `VK_IMAGE_ASPECT_COLOR_BIT` image views, then `mipLevels` **must** be 1.

• If the image format is one of those listed in Formats requiring sampler Y’C_bC_R conversion for `VK_IMAGE_ASPECT_COLOR_BIT` image views, samples **must** be `VK_SAMPLE_COUNT_1_BIT`.

• If the image format is one of those listed in Formats requiring sampler Y’C_bC_R conversion for `VK_IMAGE_ASPECT_COLOR_BIT` image views, and the ycbcrImageArrays feature is not enabled, `arrayLayers` **must** be 1.

• If format is a multi-planar format, and if `imageCreateFormatFeatures` (as defined in Image Creation Limits) does not contain `VK_FORMAT_FEATURE_DISJOINT_BIT`, then flags **must** not contain `VK_IMAGE_CREATE_DISJOINT_BIT`.

• If format is not a multi-planar format, and flags does not include `VK_IMAGE_CREATE_ALIAS_BIT`, flags **must** not contain `VK_IMAGE_CREATE_DISJOINT_BIT`.

• If tiling is `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then the `pNext` chain **must** include exactly one of `VkImageDrmFormatModifierListCreateInfoEXT` or `VkImageDrmFormatModifierExplicitCreateInfoEXT` structures.

• If the `pNext` chain includes a `VkImageDrmFormatModifierListCreateInfoEXT` or `VkImageDrmFormatModifierExplicitCreateInfoEXT` structure, then tiling **must** be `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`.

• If tiling is `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT` and flags contains `VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT`, then the `pNext` chain **must** include a `VkImageFormatListCreateInfo` structure with non-zero `viewFormatCount`.

• If flags contains `VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT` format **must** be a depth or depth/stencil format.

• If the `pNext` chain includes a `VkExternalMemoryImageCreateInfo` structure whose `handleTypes` member includes `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID`, `imageType` **must** be `VK_IMAGE_TYPE_2D`.

• If the `pNext` chain includes a `VkExternalMemoryImageCreateInfo` structure whose `handleTypes` member includes `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID`, `mipLevels` **must** either be 1 or equal to the number of levels in the complete mipmap chain based on `extent.width`, `extent.height`, and `extent.depth`.

• If the `pNext` chain includes a `VkExternalFormatANDROID` structure whose `externalFormat` member is not **0**, flags **must** not include `VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT`.
• If the pNext chain includes a VkExternalFormatANDROID structure whose externalFormat member is not 0, usage must not include any usages except VK_IMAGE_USAGE_SAMPLED_BIT.

• If the pNext chain includes a VkExternalFormatANDROID structure whose externalFormat member is not 0, tiling must be VK_IMAGE_TILING_OPTIMAL.

• If format is a depth-stencil format, usage includes VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT, and the pNext chain includes a VkImageStencilUsageCreateInfo structure, then its VkImageStencilUsageCreateInfo::stencilUsage member must also include VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT.

• If format is a depth-stencil format, usage does not include VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT, and the pNext chain includes a VkImageStencilUsageCreateInfo structure, then its VkImageStencilUsageCreateInfo::stencilUsage member must also not include VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT.

• If format is a depth-stencil format, usage includes VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT, and the pNext chain includes a VkImageStencilUsageCreateInfo structure, then its VkImageStencilUsageCreateInfo::stencilUsage member must also include VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT.

• If format is a depth-stencil format, usage does not include VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT, and the pNext chain includes a VkImageStencilUsageCreateInfo structure, then its VkImageStencilUsageCreateInfo::stencilUsage member must also not include VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT.

• If format is a depth-stencil format and the pNext chain includes a VkImageStencilUsageCreateInfo structure with its stencilUsage member including VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT, extent.width must be less than or equal to VkPhysicalDeviceLimits::maxFramebufferWidth.

• If format is a depth-stencil format and the pNext chain includes a VkImageStencilUsageCreateInfo structure with its stencilUsage member including VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT, extent.height must be less than or equal to VkPhysicalDeviceLimits::maxFramebufferHeight.

• If the multisampled storage images feature is not enabled, format is a depth-stencil format and the pNext chain includes a VkImageStencilUsageCreateInfo structure with its stencilUsage member including VK_IMAGE_USAGE_STORAGE_BIT, samples must be VK_SAMPLE_COUNT_1_BIT.

• If flags contains VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV, imageType must be VK_IMAGE_TYPE_2D or VK_IMAGE_TYPE_3D.

• If flags contains VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV, it must not contain VK_IMAGE_CREATE_CUBE_COMPATIBLE_BIT and the format must not be a depth/stencil format.

• If flags contains VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV and imageType is VK_IMAGE_TYPE_2D, extent.width and extent.height must be greater than 1.

• If flags contains VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV and imageType is VK_IMAGE_TYPE_3D, extent.width, extent.height, and extent.depth must be greater than 1.

• If usage includes VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV, imageType must be VK_IMAGE_TYPE_2D.
• If usage includes `VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV`, samples must be `VK_SAMPLE_COUNT_1_BIT`

• If usage includes `VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV`, tiling must be `VK_IMAGE_TILING_OPTIMAL`

• If flags contains `VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT`, tiling must be `VK_IMAGE_TILING_OPTIMAL`

• If flags contains `VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT`, `imageType` must be `VK_IMAGE_TYPE_2D`

• If flags contains `VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT`, flags must not contain `VK_IMAGE_CREATE_CUBE_COMPATIBLE_BIT`

• If flags contains `VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT`, `mipLevels` must be 1

---

**Valid Usage (Implicit)**

- **sType** must be `VK_STRUCTURE_TYPE_IMAGE_CREATE_INFO`

- Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkDedicatedAllocationImageCreateInfoNV`, `VkExternalFormatANDROID`, `VkExternalMemoryImageCreateInfo`, `VkImageDrmFormatModifierExplicitCreateInfoEXT`, `VkImageDrmFormatModifierListCreateInfoEXT`, `VkImageFormatListCreateInfo`, `VkImageStencilUsageCreateInfo`, or `VkImageSwapchainCreateInfoKHR`

- The `sType` value of each struct in the `pNext` chain must be unique

- **flags** must be a valid combination of `VkImageCreateFlagBits` values

- **imageType** must be a valid `VkImageType` value

- **format** must be a valid `VkFormat` value

- **samples** must be a valid `VkSampleCountFlagBits` value

- **tiling** must be a valid `VkImageTiling` value

- **usage** must be a valid combination of `VkImageUsageFlagBits` values

- **usage** must not be 0

- **sharingMode** must be a valid `VkSharingMode` value

- **initialLayout** must be a valid `VkImageLayout` value

---

The `VkImageStencilUsageCreateInfo` structure is defined as:

```c
typedef struct VkImageStencilUsageCreateInfo {
    VkStructureType      sType;
    const void*          pNext;
    VkImageUsageFlags    stencilUsage;
} VkImageStencilUsageCreateInfo;
```
or the equivalent

```c
typedef VkImageStencilUsageCreateInfo VkImageStencilUsageCreateInfoEXT;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `stencilUsage` is a bitmask of `VkImageUsageFlagBits` describing the intended usage of the stencil aspect of the image.

If the `pNext` chain of `VkImageCreateInfo` includes a `VkImageStencilUsageCreateInfo` structure, then that structure includes the usage flags specific to the stencil aspect of the image for an image with a depth-stencil format.

This structure specifies image usages which only apply to the stencil aspect of a depth/stencil format image. When this structure is included in the `pNext` chain of `VkImageCreateInfo`, the stencil aspect of the image **must** only be used as specified by `stencilUsage`. When this structure is not included in the `pNext` chain of `VkImageCreateInfo`, the stencil aspect of an image **must** only be used as specified `VkImageCreateInfo::usage`. Use of other aspects of an image are unaffected by this structure.

This structure **can** also be included in the `pNext` chain of `VkPhysicalDeviceImageFormatInfo2` to query additional capabilities specific to image creation parameter combinations including a separate set of usage flags for the stencil aspect of the image using `vkGetPhysicalDeviceImageFormatProperties2`. When this structure is not included in the `pNext` chain of `VkPhysicalDeviceImageFormatInfo2` then the implicit value of `stencilUsage` matches that of `VkPhysicalDeviceImageFormatInfo2::usage`.

### Valid Usage

- If `stencilUsage` includes `VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT`, it **must** not include bits other than `VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT` or `VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT`

### Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_IMAGE_STENCIL_USAGE_CREATE_INFO`
- `stencilUsage` **must** be a valid combination of `VkImageUsageFlagBits` values
- `stencilUsage` **must** not be 0

If the `pNext` chain includes a `VkDedicatedAllocationImageCreateInfoNV` structure, then that structure includes an enable controlling whether the image will have a dedicated memory allocation bound to it.

The `VkDedicatedAllocationImageCreateInfoNV` structure is defined as:
typedef struct VkDedicatedAllocationImageCreateInfoNV {
    VkStructureType sType;
    const void* pNext;
    VkBool32 dedicatedAllocation;
} VkDedicatedAllocationImageCreateInfoNV;

• **sType** is the type of this structure.
• **pNext** is NULL or a pointer to an extension-specific structure.
• **dedicatedAllocation** specifies whether the image will have a dedicated allocation bound to it.

**Note**
Using a dedicated allocation for color and depth/stencil attachments or other large images **may** improve performance on some devices.

**Valid Usage**

• If **dedicatedAllocation** is **VK_TRUE**, `VkImageCreateInfo::flags` must not include `VK_IMAGE_CREATE_SPARSE_BINDING_BIT`, `VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT`, or `VK_IMAGE_CREATE_SPARSE_ALIASED_BIT`.

**Valid Usage (Implicit)**

• **sType** must be `VK_STRUCTURE_TYPE_DEDICATED_ALLOCATION_IMAGE_CREATE_INFO_NV`.

To define a set of external memory handle types that **may** be used as backing store for an image, add a `VkExternalMemoryImageCreateInfo` structure to the `pNext` chain of the `VkImageCreateInfo` structure. The `VkExternalMemoryImageCreateInfo` structure is defined as:

typedef struct VkExternalMemoryImageCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkExternalMemoryHandleTypeFlags handleTypes;
} VkExternalMemoryImageCreateInfo;

or the equivalent

typedef VkExternalMemoryImageCreateInfo VkExternalMemoryImageCreateInfoKHR;

**Note**
A `VkExternalMemoryImageCreateInfo` structure must be included in the creation parameters for an image that will be bound to memory that is either exported or imported.

Chapter 11. Resource Creation | 549
• **sType** is the type of this structure.

• **pNext** is NULL or a pointer to an extension-specific structure.

• **handleTypes** is a bitmask of `VkExternalMemoryHandleTypeFlagBits` specifying one or more external memory handle types.

### Valid Usage (Implicit)

- **sType must** be `VK_STRUCTURE_TYPE_EXTERNAL_MEMORY_IMAGE_CREATE_INFO`
- **handleTypes must** be a valid combination of `VkExternalMemoryHandleTypeFlagBits` values
- **handleTypes must** not be 0

If the `pNext` chain includes a `VkExternalMemoryImageCreateInfoNV` structure, then that structure defines a set of external memory handle types that **may** be used as backing store for the image.

The `VkExternalMemoryImageCreateInfoNV` structure is defined as:

```c
typedef struct VkExternalMemoryImageCreateInfoNV {
    VkStructureType                      sType;
    const void*                          pNext;
    VkExternalMemoryHandleTypeFlagsNV    handleTypes;
} VkExternalMemoryImageCreateInfoNV;
```

• **sType** is the type of this structure.

• **pNext** is NULL or a pointer to an extension-specific structure.

• **handleTypes** is a bitmask of `VkExternalMemoryHandleTypeFlagBitsNV` specifying one or more external memory handle types.

### Valid Usage (Implicit)

- **sType must** be `VK_STRUCTURE_TYPE_EXTERNAL_MEMORY_IMAGE_CREATE_INFO_NV`
- **handleTypes must** be a valid combination of `VkExternalMemoryHandleTypeFlagBitsNV` values

To create an image with an external format, add a `VkExternalFormatANDROID` structure in the `pNext` chain of `VkImageCreateInfo`. `VkExternalFormatANDROID` is defined as:

```c
typedef struct VkExternalFormatANDROID {
    VkStructureType    sType;
    void*              pNext;
    uint64_t           externalFormat;
} VkExternalFormatANDROID;
```
• sType is the type of this structure.

• pNext is NULL or a pointer to an extension-specific structure.

• externalFormat is an implementation-defined identifier for the external format

If externalFormat is zero, the effect is as if the VkExternalFormatANDROID structure was not present. Otherwise, the image will have the specified external format.

Valid Usage

• externalFormat must be 0 or a value returned in the externalFormat member of VkAndroidHardwareBufferFormatPropertiesANDROID by an earlier call to vkGetAndroidHardwareBufferPropertiesANDROID

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_EXTERNAL_FORMAT_ANDROID

If the pNext chain of VkImageCreateInfo includes a VkImageSwapchainCreateInfoKHR structure, then that structure includes a swapchain handle indicating that the image will be bound to memory from that swapchain.

The VkImageSwapchainCreateInfoKHR structure is defined as:

```c
typedef struct VkImageSwapchainCreateInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkSwapchainKHR swapchain;
} VkImageSwapchainCreateInfoKHR;
```

• sType is the type of this structure.

• pNext is NULL or a pointer to an extension-specific structure.

• swapchain is VK_NULL_HANDLE or a handle of a swapchain that the image will be bound to.

Valid Usage

• If swapchain is not VK_NULL_HANDLE, the fields of VkImageCreateInfo must match the implied image creation parameters of the swapchain
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_IMAGE_SWAPCHAIN_CREATE_INFO_KHR`
- If `swapchain` is not `VK_NULL_HANDLE`, `swapchain` must be a valid `VkSwapchainKHR` handle

If the `pNext` list of `VkImageCreateInfo` includes a `VkImageFormatListCreateInfo` structure, then that structure contains a list of all formats that can be used when creating views of this image.

The `VkImageFormatListCreateInfo` structure is defined as:

```c
typedef struct VkImageFormatListCreateInfo {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           viewFormatCount;
    const VkFormat*    pViewFormats;
} VkImageFormatListCreateInfo;
```

or the equivalent

```c
typedef VkImageFormatListCreateInfo VkImageFormatListCreateInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `viewFormatCount` is the number of entries in the `pViewFormats` array.
- `pViewFormats` is an array which lists of all formats which can be used when creating views of this image.

If `viewFormatCount` is zero, `pViewFormats` is ignored and the image is created as if the `VkImageFormatListCreateInfo` structure were not included in the `pNext` list of `VkImageCreateInfo`.

Valid Usage

- If `viewFormatCount` is not 0, all of the formats in the `pViewFormats` array must be compatible with the format specified in the `format` field of `VkImageCreateInfo`, as described in the compatibility table.
- If `VkImageCreateInfo::flags` does not contain `VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT`, `viewFormatCount` must be 0 or 1.
- If `viewFormatCount` is not 0, `VkImageCreateInfo::format` must be in `pViewFormats`.
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_IMAGE_FORMAT_LIST_CREATE_INFO`
- If `viewFormatCount` is not 0, `pViewFormats` must be a valid pointer to an array of `viewFormatCount` valid `VkFormat` values.

If the `pNext` chain of `VkImageCreateInfo` includes a `VkImageDrmFormatModifierListCreateInfoEXT` structure, then the image will be created with one of the Linux DRM format modifiers listed in the structure. The choice of modifier is implementation-dependent.

The `VkImageDrmFormatModifierListCreateInfoEXT` structure is defined as:

```c
typedef struct VkImageDrmFormatModifierListCreateInfoEXT {
    VkStructureType sType;
    const void* pNext;
    uint32_t drmFormatModifierCount;
    const uint64_t* pDrmFormatModifiers;
} VkImageDrmFormatModifierListCreateInfoEXT;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **drmFormatModifierCount** is the length of the `pDrmFormatModifiers` array.
- **pDrmFormatModifiers** is a pointer to an array of Linux DRM format modifiers.

Valid Usage

- Each modifier in `pDrmFormatModifiers` must be compatible with the parameters in `VkImageCreateInfo` and its `pNext` chain, as determined by querying `VkPhysicalDeviceImageFormatInfo2` extended with `VkPhysicalDeviceImageDrmFormatModifierInfoEXT`.

Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_IMAGE_DRM_FORMAT_MODIFIER_LIST_CREATE_INFO_EXT`
- `pDrmFormatModifiers` must be a valid pointer to an array of `drmFormatModifierCount uint64_t` values.
- `drmFormatModifierCount` must be greater than 0.

If the `pNext` chain of `VkImageCreateInfo` includes a `VkImageDrmFormatModifierExplicitCreateInfoEXT` structure, then the image will be created with the Linux DRM format modifier and memory layout defined by the structure.
The `VkImageDrmFormatModifierExplicitCreateInfoEXT` structure is defined as:

```c
typedef struct VkImageDrmFormatModifierExplicitCreateInfoEXT {
    VkStructureType sType;
    const void* pNext;
    uint64_t drmFormatModifier;
    uint32_t drmFormatModifierPlaneCount;
    const VkSubresourceLayout* pPlaneLayouts;
} VkImageDrmFormatModifierExplicitCreateInfoEXT;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `drmFormatModifier` is the Linux DRM format modifier with which the image will be created.
- `drmFormatModifierPlaneCount` is the number of memory planes in the image (as reported by `VkDrmFormatModifierPropertiesEXT`) as well as the length of the `pPlaneLayouts` array.
- `pPlaneLayouts` is a pointer to an array of `VkSubresourceLayout` structures describing the image's memory planes.

The \(i\)th member of `pPlaneLayouts` describes the layout of the image's \(i\)th memory plane (that is, `VK_IMAGE_ASPECT_MEMORY_PLANE_i_BIT_EXT`). In each element of `pPlaneLayouts`, the implementation must ignore size. The implementation calculates the size of each plane, which the application can query with `vkGetImageSubresourceLayout`.

When creating an image with `VkImageDrmFormatModifierExplicitCreateInfoEXT`, it is the application's responsibility to satisfy all valid usage requirements. However, the implementation must validate that the provided `pPlaneLayouts`, when combined with the provided `drmFormatModifier` and other creation parameters in `VkImageCreateInfo` and its `pNext` chain, produce a valid image. (This validation is necessarily implementation-dependent and outside the scope of Vulkan, and therefore not described by valid usage requirements). If this validation fails, then `vkCreateImage` returns `VK_ERROR_INVALID_DRM_FORMAT_MODIFIER_PLANE_LAYOUT_EXT`. 
Valid Usage

• **drmFormatModifier** must be compatible with the parameters in `VkImageCreateInfo` and its `pNext` chain, as determined by querying `VkPhysicalDeviceImageFormatInfo2` extended with `VkPhysicalDeviceImageDrmFormatModifierInfoEXT`.

• **drmFormatModifierPlaneCount** must be equal to the `VkDrmFormatModifierPropertiesEXT::drmFormatModifierPlaneCount` associated with `VkImageCreateInfo::format` and `drmFormatModifier`, as found by querying `VkDrmFormatModifierPropertiesListEXT`.

• For each element of `pPlaneLayouts`, `size` must be 0.

• For each element of `pPlaneLayouts`, `arrayPitch` must be 0 if `VkImageCreateInfo::arrayLayers` is 1.

• For each element of `pPlaneLayouts`, `depthPitch` must be 0 if `VkImageCreateInfo::extent.depth` is 1.

Valid Usage (Implicit)

• **sType** must be `VK_STRUCTURE_TYPE_IMAGE_DRM_FORMAT_MODIFIER_EXPLICIT_CREATE_INFO_EXT`.

• If `drmFormatModifierPlaneCount` is not 0, `pPlaneLayouts` must be a valid pointer to an array of `drmFormatModifierPlaneCount` `VkSubresourceLayout` structures.

Bits which can be set in `VkImageCreateInfo::usage`, specifying intended usage of an image, are:

```c
typedef enum VkImageUsageFlagBits {
    VK_IMAGE_USAGE_TRANSFER_SRC_BIT = 0x00000001,
    VK_IMAGE_USAGE_TRANSFER_DST_BIT = 0x00000002,
    VK_IMAGE_USAGE_SAMPLED_BIT = 0x00000004,
    VK_IMAGE_USAGE_STORAGE_BIT = 0x00000008,
    VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT = 0x00000010,
    VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT = 0x00000020,
    VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT = 0x00000040,
    VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT = 0x00000080,
    VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV = 0x00000100,
    VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_EXT = 0x00000200,
    VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT_EXT = 0x00000400,
    VK_IMAGE_USAGE_SHADER_READ_ONLY_OPAQUE_ATTACHMENT_BIT_EXT = 0x00000800,
    VK_IMAGE_USAGE_DEPTH_STENCIL_READ_ONLY_ATTACHMENT_BIT_EXT = 0x00001000,
    VK_IMAGE_USAGE_FRAGMENT_DENSITY_ATTACHMENT_BIT_EXT = 0x00002000,
    VK_IMAGE_USAGE_GLSL_FRAGMENT_DENSITY_ATTACHMENT_BIT_NV = 0x00004000
} VkImageUsageFlagBits;
```

- **VK_IMAGE_USAGE_TRANSFER_SRC_BIT** specifies that the image can be used as the source of a transfer command.
- **VK_IMAGE_USAGE_TRANSFER_DST_BIT** specifies that the image can be used as the destination of a transfer command.
- **VK_IMAGE_USAGE_SAMPLED_BIT** specifies that the image can be used to create a `VkImageView` suitable for occupying a `VkDescriptorSet` slot either of type `VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE` or `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`, and be sampled by a shader.
• **VK_IMAGE_USAGE_STORAGE_BIT** specifies that the image can be used to create a *VkImageView* suitable for occupying a *VkDescriptorSet* slot of type **VK_DESCRIPTOR_TYPE_STORAGE_IMAGE**.

• **VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT** specifies that the image can be used to create a *VkImageView* suitable for use as a color or resolve attachment in a *VkFramebuffer*.

• **VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT** specifies that the image can be used to create a *VkImageView* suitable for use as a depth/stencil or depth/stencil resolve attachment in a *VkFramebuffer*.

• **VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT** specifies that the memory bound to this image will have been allocated with the **VK_MEMORY_PROPERTY_LAZILY_ALLOCATED_BIT** (see Memory Allocation for more detail). This bit can be set for any image that can be used to create a *VkImageView* suitable for use as a color, resolve, depth/stencil, or input attachment.

• **VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT** specifies that the image can be used to create a *VkImageView* suitable for occupying *VkDescriptorSet* slot of type **VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT**; be read from a shader as an input attachment; and be used as an input attachment in a framebuffer.

• **VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV** specifies that the image can be used to create a *VkImageView* suitable for use as a shading rate image.

• **VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_EXT** specifies that the image can be used to create a *VkImageView* suitable for use as a fragment density map image.

typedef VkFlags VkImageUsageFlags;

*VkImageUsageFlags* is a bitmask type for setting a mask of zero or more *VkImageUsageFlagBits*.

Bits which can be set in *VkImageCreateInfo::flags*, specifying additional parameters of an image, are:
typedef enum VkImageCreateFlagBits {
    VK_IMAGE_CREATE_SPARSE_BINDING_BIT = 0x00000001,
    VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT = 0x00000002,
    VK_IMAGE_CREATE_SPARSE_ALIASED_BIT = 0x00000004,
    VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT = 0x00000008,
    VK_IMAGE_CREATE_CUBE_COMPATIBLE_BIT = 0x00000010,
    VK_IMAGE_CREATE_ALIAS_BIT = 0x00000400,
    VK_IMAGE_CREATE_SPLIT_INSTANCE_BIND_REGIONS_BIT = 0x00000040,
    VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT = 0x00000020,
    VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT = 0x00000080,
    VK_IMAGE_CREATE_EXTENDED_USAGE_BIT = 0x00000100,
    VK_IMAGE_CREATE_DISJOINT_BIT = 0x00000200,
    VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV = 0x00002000,
    VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT = 0x00001000,
    VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT = 0x00004000,
    VK_IMAGE_CREATE_SPLIT_INSTANCE_BIND_REGIONS_BIT_KHR = VK_IMAGE_CREATE_SPLIT_INSTANCE_BIND_REGIONS_BIT,
    VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT_KHR = VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT,
    VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT_KHR = VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT,
    VK_IMAGE_CREATE_EXTENDED_USAGE_BIT_KHR = VK_IMAGE_CREATE_EXTENDED_USAGE_BIT,
    VK_IMAGE_CREATE_DISJOINT_BIT_KHR = VK_IMAGE_CREATE_DISJOINT_BIT,
    VK_IMAGE_CREATE_ALIAS_BIT_KHR = VK_IMAGE_CREATE_ALIAS_BIT,
} VkImageCreateFlagBits;

• **VK_IMAGE_CREATE_SPARSE_BINDING_BIT** specifies that the image will be backed using sparse memory binding.

• **VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT** specifies that the image can be partially backed using sparse memory binding. Images created with this flag must also be created with the **VK_IMAGE_CREATE_SPARSE_BINDING_BIT** flag.

• **VK_IMAGE_CREATE_SPARSE_ALIASED_BIT** specifies that the image will be backed using sparse memory binding with memory ranges that might also simultaneously be backing another image (or another portion of the same image). Images created with this flag must also be created with the **VK_IMAGE_CREATE_SPARSE_BINDING_BIT** flag.

• **VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT** specifies that the image can be used to create a `VkImageView` with a different format from the image. For multi-planar formats, **VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT** specifies that a `VkImageView` can be created of a *plane* of the image.

• **VK_IMAGE_CREATE_CUBE_COMPATIBLE_BIT** specifies that the image can be used to create a `VkImageView` of type `VK_IMAGE_VIEW_TYPE_CUBE` or `VK_IMAGE_VIEW_TYPE_CUBE_ARRAY`.

• **VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT** specifies that the image can be used to create a `VkImageView` of type `VK_IMAGE_VIEW_TYPE_2D` or `VK_IMAGE_VIEW_TYPE_2D_ARRAY`.

• **VK_IMAGE_CREATE_SPLIT_INSTANCE_BIND_REGIONS_BIT** specifies that the image can be used with a non-zero value of the `splitInstanceBindRegionCount` member of a `VkBindImageMemoryDeviceGroupInfo` structure passed into `vkBindImageMemory2`. This flag
also has the effect of making the image use the standard sparse image block dimensions.

- **VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT** specifies that the image having a compressed format **can** be used to create a *VkImageView* with an uncompressed format where each texel in the image view corresponds to a compressed texel block of the image.

- **VK_IMAGE_CREATE_EXTENDED_USAGE_BIT** specifies that the image **can** be created with usage flags that are not supported for the format the image is created with but are supported for at least one format a *VkImageView* created from the image **can** have.

- **VK_IMAGE_CREATE_DISJOINT_BIT** specifies that an image with a multi-planar format **must** have each plane separately bound to memory, rather than having a single memory binding for the whole image; the presence of this bit distinguishes a **disjoint image** from an image without this bit set.

- **VK_IMAGE_CREATE_ALIAS_BIT** specifies that two images created with the same creation parameters and aliased to the same memory **can** interpret the contents of the memory consistently with each other, subject to the rules described in the Memory Aliasing section. This flag further specifies that each plane of a **disjoint** image **can** share an in-memory non-linear representation with single-plane images, and that a single-plane image **can** share an in-memory non-linear representation with a plane of a multi-planar disjoint image, according to the rules in Compatible formats of planes of multi-planar formats. If the pNext chain includes a *VkExternalMemoryImageCreateInfo* or *VkExternalMemoryImageCreateInfoNV* structure whose handleTypes member is not 0, it is as if **VK_IMAGE_CREATE_ALIAS_BIT** is set.

- **VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT** specifies that an image with a depth or depth/stencil format **can** be used with custom sample locations when used as a depth/stencil attachment.

- **VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV** specifies that the image is a **corner-sampled image**.

- **VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT** specifies that an image **can** be in a subsampled format which **may** be more optimal when written as an attachment by a render pass that has a fragment density map attachment. Accessing a subsampled image has additional considerations:
  
  - Image data read as an image sampler is undefined if the sampler was not created with **flags** containing **VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT** or was not sampled through the use of a combined image sampler with an immutable sampler in *VkDescriptorSetLayoutBinding*.
  
  - Image data read with an input attachment is undefined if the contents were not written as an attachment in an earlier subpass of the same render pass.
  
  - Image data read with load operations **may** be resampled to the fragment density of the render pass.
  
  - Image contents outside of the render area become undefined if the image is stored as a render pass attachment.

See **Sparse Resource Features** and **Sparse Physical Device Features** for more details.

```c
typedef VkFlags VkImageCreateFlags;
```

**VkImageCreateFlags** is a bitmask type for setting a mask of zero or more **VkImageCreateFlagBits**.

558 | Chapter 11. Resource Creation
Possible values of `VkImageCreateInfo::imageType`, specifying the basic dimensionality of an image, are:

```c
typedef enum VkImageType {
    VK_IMAGE_TYPE_1D = 0,
    VK_IMAGE_TYPE_2D = 1,
    VK_IMAGE_TYPE_3D = 2,
} VkImageType;
```

- `VK_IMAGE_TYPE_1D` specifies a one-dimensional image.
- `VK_IMAGE_TYPE_2D` specifies a two-dimensional image.
- `VK_IMAGE_TYPE_3D` specifies a three-dimensional image.

Possible values of `VkImageCreateInfo::tiling`, specifying the tiling arrangement of texel blocks in an image, are:

```c
typedef enum VkImageTiling {
    VK_IMAGE_TILING_OPTIMAL = 0,
    VK_IMAGE_TILING_LINEAR = 1,
    VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT = 1000158000,
} VkImageTiling;
```

- `VK_IMAGE_TILING_OPTIMAL` specifies optimal tiling (texels are laid out in an implementation-dependent arrangement, for more optimal memory access).
- `VK_IMAGE_TILING_LINEAR` specifies linear tiling (texels are laid out in memory in row-major order, possibly with some padding on each row).
- `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT` indicates that the image's tiling is defined by a Linux DRM format modifier. The modifier is specified at image creation with `VkImageDrmFormatModifierListCreateInfoEXT` or `VkImageDrmFormatModifierExplicitCreateInfoEXT`, and can be queried with `vkGetImageDrmFormatModifierPropertiesEXT`.

To query the memory layout of an image subresource, call:

```c
void vkGetImageSubresourceLayout(
    VkDevice device,                        // device,
    VkImage image,                         // image,
    const VkImageSubresource* pSubresource, // pSubresource,
    VkSubresourceLayout* pLayout);         // pLayout);
```

- `device` is the logical device that owns the image.
- `image` is the image whose layout is being queried.
- `pSubresource` is a pointer to a `VkImageSubresource` structure selecting a specific image for the image subresource.
• `pLayout` is a pointer to a `VkSubresourceLayout` structure in which the layout is returned.

If the image is **linear**, then the returned layout is valid for **host access**.

If the image's tiling is `VK_IMAGE_TILING_LINEAR` and its format is a **multi-planar format**, then `vkGetImageSubresourceLayout` describes one **format plane** of the image. If the image's tiling is `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then `vkGetImageSubresourceLayout` describes one **memory plane** of the image. If the image's tiling is `VK_IMAGE_TILING_LINEAR` and its format is a **multi-planar format** with two planes, the **aspectMask** member of `pSubresource` **must** be `VK_IMAGE_ASPECT_PLANE_0_BIT` or `VK_IMAGE_ASPECT_PLANE_1_BIT`. If the image's tiling is `VK_IMAGE_TILING_LINEAR` and its format is a **multi-planar format** with three planes, the **aspectMask** member of `pSubresource` **must** be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT` or `VK_IMAGE_ASPECT_PLANE_2_BIT`. If `image` was created with the `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID` external memory handle type, then `image` **must** be bound to memory.

`vkGetImageSubresourceLayout` is invariant for the lifetime of a single image. However, the subresource layout of images in Android hardware buffer external memory is not known until the image has been bound to memory, so applications **must** not call `vkGetImageSubresourceLayout` for such an image before it has been bound.

### Valid Usage

- `image` **must** have been created with **tiling** equal to `VK_IMAGE_TILING_LINEAR` or `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`
- The **aspectMask** member of `pSubresource` **must** only have a single bit set
- The **mipLevel** member of `pSubresource` **must** be less than the **mipLevels** specified in `VkImageCreateInfo` when `image` was created
- The **arrayLayer** member of `pSubresource` **must** be less than the **arrayLayers** specified in `VkImageCreateInfo` when `image` was created
- If the **tiling** of the `image` is `VK_IMAGE_TILING_LINEAR` and its **format** is a **multi-planar format** with two planes, the **aspectMask** member of `pSubresource` **must** be `VK_IMAGE_ASPECT_PLANE_0_BIT` or `VK_IMAGE_ASPECT_PLANE_1_BIT`
- If the **tiling** of the `image` is `VK_IMAGE_TILING_LINEAR` and its **format** is a **multi-planar format** with three planes, the **aspectMask** member of `pSubresource` **must** be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT` or `VK_IMAGE_ASPECT_PLANE_2_BIT`
- If `image` was created with the `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID` external memory handle type, then `image` **must** be bound to memory
- If the **tiling** of the `image` is `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then the **aspectMask** member of `pSubresource` **must** be `VK_IMAGE_ASPECT_MEMORY_PLANE_i_BIT_EXT` and the index `i` **must** be less than the `VkDrmFormatModifierPropertiesEXT::drmFormatModifierPlaneCount` associated with the image’s **format** and `VkImageDrmFormatModifierPropertiesEXT::drmFormatModifier`
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **image** must be a valid `VkImage` handle
- **pSubresource** must be a valid pointer to a valid `VkImageSubresource` structure
- **pLayout** must be a valid pointer to a `VkSubresourceLayout` structure
- **image** must have been created, allocated, or retrieved from **device**

The `VkImageSubresource` structure is defined as:

```c
typedef struct VkImageSubresource {
    VkImageAspectFlags aspectMask;
    uint32_t mipLevel;
    uint32_t arrayLayer;
} VkImageSubresource;
```

- **aspectMask** is a `VkImageAspectFlags` selecting the image **aspect**.
- **mipLevel** selects the mipmap level.
- **arrayLayer** selects the array layer.

Valid Usage (Implicit)

- **aspectMask** must be a valid combination of `VkImageAspectFlagBits` values
- **aspectMask** must not be 0

Information about the layout of the image subresource is returned in a `VkSubresourceLayout` structure:

```c
typedef struct VkSubresourceLayout {
    VkDeviceSize offset;
    VkDeviceSize size;
    VkDeviceSize rowPitch;
    VkDeviceSize arrayPitch;
    VkDeviceSize depthPitch;
} VkSubresourceLayout;
```

- **offset** is the byte offset from the start of the image or the plane where the image subresource begins.
- **size** is the size in bytes of the image subresource. **size** includes any extra memory that is required based on **rowPitch**.
- **rowPitch** describes the number of bytes between each row of texels in an image.
- `arrayPitch` describes the number of bytes between each array layer of an image.
- `depthPitch` describes the number of bytes between each slice of a 3D image.

If the image is linear, then `rowPitch`, `arrayPitch` and `depthPitch` describe the layout of the image subresource in linear memory. For uncompressed formats, `rowPitch` is the number of bytes between texels with the same x coordinate in adjacent rows (y coordinates differ by one). `arrayPitch` is the number of bytes between texels with the same x and y coordinate in adjacent array layers of the image (array layer values differ by one). `depthPitch` is the number of bytes between texels with the same x and y coordinate in adjacent slices of a 3D image (z coordinates differ by one). Expressed as an addressing formula, the starting byte of a texel in the image subresource has address:

```plaintext
// (x,y,z,layer) are in texel coordinates
address(x,y,z,layer) = layer*arrayPitch + z*depthPitch + y*rowPitch + x*elementSize + offset
```

For compressed formats, the `rowPitch` is the number of bytes between compressed texel blocks in adjacent rows. `arrayPitch` is the number of bytes between compressed texel blocks in adjacent array layers. `depthPitch` is the number of bytes between compressed texel blocks in adjacent slices of a 3D image.

```plaintext
// (x,y,z,layer) are in compressed texel block coordinates
address(x,y,z,layer) = layer*arrayPitch + z*depthPitch + y*rowPitch + x *compressedTexelBlockByteSize + offset;
```

The value of `arrayPitch` is undefined for images that were not created as arrays. `depthPitch` is defined only for 3D images.

If the image has a single-plane color format and its tiling is `VK_IMAGE_TILING_LINEAR`, then the `aspectMask` member of `VkImageSubresource` must be `VK_IMAGE_ASPECT_COLOR_BIT`.

If the image has a depth/stencil format and its tiling is `VK_IMAGE_TILING_LINEAR`, then `aspectMask` must be either `VK_IMAGE_ASPECT_DEPTH_BIT` or `VK_IMAGE_ASPECT_STENCIL_BIT`. On implementations that store depth and stencil aspects separately, querying each of these image subresource layouts will return a different `offset` and `size` representing the region of memory used for that aspect. On implementations that store depth and stencil aspects interleaved, the same `offset` and `size` are returned and represent the interleaved memory allocation.

If the image has a multi-planar format and its tiling is `VK_IMAGE_TILING_LINEAR`, then the `aspectMask` member of `VkImageSubresource` must be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT`, or (for 3-plane formats only) `VK_IMAGE_ASPECT_PLANE_2_BIT`. Querying each of these image subresource layouts will return a different `offset` and `size` representing the region of memory used for that plane. If the image is `disjoint`, then the `offset` is relative to the base address of the plane. If the image is `non-disjoint`, then the `offset` is relative to the base address of the image.

If the image's tiling is `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then the `aspectMask` member of `VkImageSubresource` must be one of `VK_IMAGE_ASPECT_MEMORY_PLANE_i_BIT_EXT`, where the maximum allowed plane index `i` is defined by the `VkDrmFormatModifierPropertiesEXT`
::drmFormatModifierPlaneCount associated with the image's VkImageCreateInfo::format and modifier. The memory range used by the subresource is described by offset and size. If the image is disjoint, then the offset is relative to the base address of the memory plane. If the image is non-disjoint, then the offset is relative to the base address of the image. If the image is non-linear, then rowPitch, arrayPitch, and depthPitch have an implementation-dependent meaning.

If an image was created with VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT, then the image has a Linux DRM format modifier. To query the modifier, call:

```c
VkResult vkGetImageDrmFormatModifierPropertiesEXT(
    VkDevice device,        // Logical device that owns the image.
    VkImage image,          // Image to query.
    VkImageDrmFormatModifierPropertiesEXT* pProperties);    // Pointer to properties of the image's DRM format modifier.
```

- **device** is the logical device that owns the image.
- **image** is the queried image.
- **pProperties** will return properties of the image's DRM format modifier.

### Valid Usage

- **image** must have been created with tiling equal to VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT.

### Valid Usage (Implicit)

- **device** must be a valid VkDevice handle.
- **image** must be a valid VkImage handle.
- **pProperties** must be a valid pointer to a VkImageDrmFormatModifierPropertiesEXT structure.
- **image** must have been created, allocated, or retrieved from device.

### Return Codes

**Success**
- VK_SUCCESS

The VkImageDrmFormatModifierPropertiesEXT structure is defined as:
typedef struct VkImageDrmFormatModifierPropertiesEXT {
    VkStructureType    sType;
    void*              pNext;
    uint64_t           drmFormatModifier;
} VkImageDrmFormatModifierPropertiesEXT;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `drmFormatModifier` returns the image's **Linux DRM format modifier**.

If the image was created with `VkImageDrmFormatModifierListCreateInfoEXT`, then the returned `drmFormatModifier` must belong to the list of modifiers provided at time of image creation in `VkImageDrmFormatModifierListCreateInfoEXT::pDrmFormatModifiers`. If the image was created with `VkImageDrmFormatModifierExplicitCreateInfoEXT`, then the returned `drmFormatModifier` must be the modifier provided at time of image creation in `VkImageDrmFormatModifierExplicitCreateInfoEXT::drmFormatModifier`.

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_IMAGE_DRM_FORMAT_MODIFIER_PROPERTIES_EXT`
- `pNext` must be `NULL`

To destroy an image, call:

```c
void vkDestroyImage(
    VkDevice device,
    VkImage image,
    const VkAllocationCallbacks* pAllocator);
```

- `device` is the logical device that destroys the image.
- `image` is the image to destroy.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

### Valid Usage

- All submitted commands that refer to `image`, either directly or via a `VkImageView`, must have completed execution
- If `VkAllocationCallbacks` were provided when `image` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `image` was created, `pAllocator` must be `NULL`
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- If **image** is not `VK_NULL_HANDLE`, **image** must be a valid `VkImage` handle
- If **pAllocator** is not `NULL`, **pAllocator** must be a valid pointer to a valid `VkAllocationCallbacks` structure
- If **image** is a valid handle, it must have been created, allocated, or retrieved from **device**

Host Synchronization

- Host access to **image** must be externally synchronized

11.3.1. Image Format Features

Valid uses of a `VkImage` may depend on the image's `format features`, defined below. Such constraints are documented in the affected valid usage statement.

- If the image was created with `VK_IMAGE_TILING_LINEAR`, then its set of `format features` is the value of `VkFormatProperties::linearTilingFeatures` found by calling `vkGetPhysicalDeviceFormatProperties` on the same `format` as `VkImageCreateInfo::format`.

- If the image was created with `VK_IMAGE_TILING_OPTIMAL`, but without an Android hardware buffer external format, then its set of `format features` is the value of `VkFormatProperties::optimalTilingFeatures` found by calling `vkGetPhysicalDeviceFormatProperties` on the same `format` as `VkImageCreateInfo::format`.

- If the image was created with an Android hardware buffer external format, then its set of `format features` is the value of `VkAndroidHardwareBufferFormatPropertiesANDROID::formatFeatures` found by calling `vkGetAndroidHardwareBufferPropertiesANDROID` on the Android hardware buffer that was imported to the `VkDeviceMemory` to which the image is bound.

- If the image was created with `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then:
  - The image's DRM format modifier is the value of `VkImageDrmFormatModifierListCreateInfoEXT::drmFormatModifier` found by calling `vkGetImageDrmFormatModifierPropertiesEXT`.
  - Let `VkDrmFormatModifierPropertiesListEXT::pDrmFormatModifierProperties` be the array found by calling `vkGetPhysicalDeviceFormatProperties2` on the same `format` as `VkImageCreateInfo::format`.
  - Let `VkDrmFormatModifierPropertiesEXT prop` be an array element whose `drmFormatModifier` member is the value of the image's DRM format modifier.
  - Then the image set of `format features` is the value of taking the bitwise intersection over the collected `prop::drmFormatModifierTilingFeatures`. 

11.3.2. Corner-Sampled Images

A *corner-sampled image* is an image where unnormalized texel coordinates are centered on integer values rather than half-integer values.

A corner-sampled image has a number of differences compared to conventional texture image:

- Texels are centered on integer coordinates. See [Unnormalized Texel Coordinate Operations](#).
- Normalized coordinates are scaled using $\text{coord} \times (\text{dim} - 1)$ rather than $\text{coord} \times \text{dim}$, where $\text{dim}$ is the size of one dimension of the image. See [normalized texel coordinate transform](#).
- Partial derivatives are scaled using $\text{coord} \times (\text{dim} - 1)$ rather than $\text{coord} \times \text{dim}$. See [Scale Factor Operation](#).
- Calculation of the next higher lod size goes according to $\lceil \text{dim} / 2 \rceil$ rather than $\lfloor \text{dim} / 2 \rfloor$. See [Image Miplevel Sizing](#).
- The minimum level size is 2x2 for 2D images and 2x2x2 for 3D images. See [Image Miplevel Sizing](#).

Corner-sampling is only supported for 2D and 3D images. When sampling a corner-sampled image, the sampler addressing mode **must** be [VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE](#). Corner-sampled images are not supported as cubemaps or depth/stencil images.

11.3.3. Image Miplevel Sizing

A *complete mipmap chain* is the full set of miplevels, from the largest miplevel provided, down to the *minimum mipmap size*.

**Conventional Images**

For conventional images, the dimensions of each successive mipmap level, $n+1$, are:

$$
\text{width}_{n+1} = \max(\lfloor \text{width}_n / 2 \rfloor , 1)
$$

$$
\text{height}_{n+1} = \max(\lfloor \text{height}_n / 2 \rfloor , 1)
$$

$$
\text{depth}_{n+1} = \max(\lfloor \text{depth}_n / 2 \rfloor , 1)
$$

where $\text{width}_n$, $\text{height}_n$, and $\text{depth}_n$ are the dimensions of the next larger mipmap level, $n$.

The minimum mipmap size is:

- 1 for one-dimensional images,
- 1x1 for two-dimensional images, and
- 1x1x1 for three-dimensional images.

The number of levels in a complete mipmap chain is:
\[ \lceil \log_2 (\max(\text{width}_0, \text{height}_0, \text{depth}_0)) \rceil + 1 \]

where \( \text{width}_0, \text{height}_0, \) and \( \text{depth}_0 \) are the dimensions of the largest (most detailed) mipmap level, \( 0 \).

**Corner-Sampled Images**

For corner-sampled images, the dimensions of each successive mipmap level, \( n+1 \), are:

\[
\begin{align*}
\text{width}_{n+1} &= \max(\lceil \text{width}_n/2 \rceil, 2) \\
\text{height}_{n+1} &= \max(\lceil \text{height}_n/2 \rceil, 2) \\
\text{depth}_{n+1} &= \max(\lceil \text{depth}_n/2 \rceil, 2)
\end{align*}
\]

where \( \text{width}_n, \text{height}_n, \) and \( \text{depth}_n \) are the dimensions of the next larger mipmap level, \( n \).

The minimum mipmap size is:

- 2x2 for two-dimensional images, and
- 2x2x2 for three-dimensional images.

The number of levels in a complete mipmap chain is:

\[ \lceil \log_2 (\max(\text{width}_0, \text{height}_0, \text{depth}_0)) \rceil \]

where \( \text{width}_0, \text{height}_0, \) and \( \text{depth}_0 \) are the dimensions of the largest (most detailed) mipmap level, \( 0 \).

### 11.4. Image Layouts

Images are stored in implementation-dependent opaque layouts in memory. Each layout has limitations on what kinds of operations are supported for image subresources using the layout. At any given time, the data representing an image subresource in memory exists in a particular layout which is determined by the most recent layout transition that was performed on that image subresource. Applications have control over which layout each image subresource uses, and they can transition an image subresource from one layout to another. Transitions can happen with an image memory barrier, included as part of a `vkCmd_pipelineBarrier` or a `vkCmdWaitEvents` command buffer command (see [Image Memory Barriers](#)), or as part of a subpass dependency within a render pass (see [VkSubpassDependency](#)). The image layout is per-image subresource, and separate image subresources of the same image can be in different layouts at the same time with one exception - depth and stencil aspects of a given image subresource must always be in the same layout.
Note

Each layout may offer optimal performance for a specific usage of image memory. For example, an image with a layout of VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL may provide optimal performance for use as a color attachment, but be unsupported for use in transfer commands. Applications can transition an image subresource from one layout to another in order to achieve optimal performance when the image subresource is used for multiple kinds of operations. After initialization, applications need not use any layout other than the general layout, though this may produce suboptimal performance on some implementations.

Upon creation, all image subresources of an image are initially in the same layout, where that layout is selected by the VkImageCreateInfo::initialLayout member. The initialLayout must be either VK_IMAGE_LAYOUT_UNDEFINED or VK_IMAGE_LAYOUT_PREINITIALIZED. If it is VK_IMAGE_LAYOUT_PREINITIALIZED, then the image data can be preinitialized by the host while using this layout, and the transition away from this layout will preserve that data. If it is VK_IMAGE_LAYOUT_UNDEFINED, then the contents of the data are considered to be undefined, and the transition away from this layout is not guaranteed to preserve that data. For either of these initial layouts, any image subresources must be transitioned to another layout before they are accessed by the device.

Host access to image memory is only well-defined for linear images and for image subresources of those images which are currently in either the VK_IMAGE_LAYOUT_PREINITIALIZED or VK_IMAGE_LAYOUT_GENERAL layout. Calling vkGetImageSubresourceLayout for a linear image returns a subresource layout mapping that is valid for either of those image layouts.

The set of image layouts consists of:
typedef enum VkImageLayout {
    VK_IMAGE_LAYOUT_UNDEFINED = 0,
    VK_IMAGE_LAYOUT_GENERAL = 1,
    VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL = 2,
    VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL = 3,
    VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL = 4,
    VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL = 5,
    VK_IMAGE_LAYOUT_TRANSFER_SRC_OPTIMAL = 6,
    VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL = 7,
    VK_IMAGE_LAYOUT_PREINITIALIZED = 8,
    VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL_KHR = 1000117000,
    VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL_KHR = 1000117000,
    VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL_KHR = 1000117001,
    VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL_KHR = 1000117001,
    VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL_KHR = 1000241000,
    VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL_KHR = 1000241001,
    VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL_KHR = 1000241002,
    VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL_KHR = 1000241003,
    VK_IMAGE_LAYOUT_PRESENT_SRC_KHR = 1000001002,
    VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR = 1000111000,
    VK_IMAGE_LAYOUT_SHADING_RATE_OPTIMAL_NV = 1000164003,
    VK_IMAGE_LAYOUT_FRAGMENT_DENSITY_MAP_OPTIMAL_EXT = 1000218000,
    VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL,
    VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL,
    VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL,
    VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL,
    VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL_KHR = VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL,
    VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL_KHR = VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL,
    VK_IMAGE_LAYOUT_PRESENT_SRC_KHR = VK_IMAGE_LAYOUT_PRESENT_SRC_KHR,
    VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR = VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR,
    VK_IMAGE_LAYOUT_SHADING_RATE_OPTIMAL_NV = VK_IMAGE_LAYOUT_SHADING_RATE_OPTIMAL_NV,
    VK_IMAGE_LAYOUT_FRAGMENT_DENSITY_MAP_OPTIMAL_EXT = VK_IMAGE_LAYOUT_FRAGMENT_DENSITY_MAP_OPTIMAL_EXT,
    VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL_KHR = VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL_KHR = VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_PRESENT_SRC_KHR = VK_IMAGE_LAYOUT_PRESENT_SRC_KHR,
    VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR = VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR,
    VK_IMAGE_LAYOUT_SHADING_RATE_OPTIMAL_NV = VK_IMAGE_LAYOUT_SHADING_RATE_OPTIMAL_NV,
    VK_IMAGE_LAYOUT_FRAGMENT_DENSITY_MAP_OPTIMAL_EXT = VK_IMAGE_LAYOUT_FRAGMENT_DENSITY_MAP_OPTIMAL_EXT,
    VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL_KHR = VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL_KHR = VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL_KHR = VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL_KHR,
    VK_IMAGE_LAYOUT_PRESENT_SRC_KHR = VK_IMAGE_LAYOUT_PRESENT_SRC_KHR,
} VkImageLayout;

The type(s) of device access supported by each layout are:

- **VK_IMAGE_LAYOUT_UNDEFINED** does not support device access. This layout must only be used as the initialLayout member of VkImageCreateInfo or VkAttachmentDescription, or as the oldLayout in an image transition. When transitioning out of this layout, the contents of the memory are not guaranteed to be preserved.

- **VK_IMAGE_LAYOUT_PREINITIALIZED** does not support device access. This layout must only be used as the initialLayout member of VkImageCreateInfo or VkAttachmentDescription, or as the oldLayout in an image transition. When transitioning out of this layout, the contents of the memory are preserved. This layout is intended to be used as the initial layout for an image whose contents are written by the host, and hence the data can be written to memory immediately, without first executing a layout transition. Currently, VK_IMAGE_LAYOUT_PREINITIALIZED is only useful with linear images because there is not a standard layout defined for VK_IMAGE_TILING_OPTIMAL images.
• **VK_IMAGE_LAYOUT_GENERAL** supports all types of device access.

• **VK_IMAGE_LAYOUT_COLOR_ATTACHMENT_OPTIMAL** must only be used as a color or resolve attachment in a VkFramebuffer. This layout is valid only for image subresources of images created with the **VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT** usage bit enabled.

• **VK_IMAGE_LAYOUT_DEPTH_STENCIL_ATTACHMENT_OPTIMAL** specifies a layout for both the depth and stencil aspects of a depth/stencil format image allowing read and write access as a depth/stencil attachment. It is equivalent to **VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_OPTIMAL** and **VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL**.

• **VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL** specifies a layout for both the depth and stencil aspects of a depth/stencil format image allowing read only access as a depth/stencil attachment or in shaders. It is equivalent to **VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL** and **VK_IMAGE_LAYOUT_STENCIL_READ_ONLY_OPTIMAL**.

• **VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL** specifies a layout for depth/stencil format images allowing read and write access to the stencil aspect as a stencil attachment, and read only access to the depth aspect as a depth attachment or in shaders. It is equivalent to **VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_OPTIMAL** and **VK_IMAGE_LAYOUT_STENCIL_ATTACHMENT_OPTIMAL**.

• **VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL** specifies a layout for depth/stencil format images allowing read only access as a depth attachment or in shaders. This layout is valid only for image subresources of images created with the **VK_IMAGE_USAGE_SAMPLED_BIT** or **VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT** usage bit enabled.

• **VK_IMAGE_LAYOUT_TRANSFER_SRC_OPTIMAL** must only be used as a source image of a transfer command (see the definition of **VK_PIPELINE_STAGE_TRANSFER_BIT**). This layout is valid only for image subresources of images created with the **VK_IMAGE_USAGE_TRANSFER_SRC_BIT** usage bit enabled.

• **VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL** must only be used as a destination image of a transfer command. This layout is valid only for image subresources of images created with the **VK_IMAGE_USAGE_TRANSFER_DST_BIT** usage bit enabled.

• **VK_IMAGE_LAYOUT_PRESENT_SRC_KHR** must only be used for presenting a presentable image for display. A swapchain’s image must be transitioned to this layout before calling **vkQueuePresentKHR**, and must be transitioned away from this layout after calling **vkAcquireNextImageKHR**.
• **VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR** is valid only for shared presentable images, and **must** be used for any usage the image supports.

• **VK_IMAGE_LAYOUT_SHADING_RATE_OPTIMAL_NV** **must** only be used as a read-only shading-rate-image. This layout is valid only for image subresources of images created with the **VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV** usage bit enabled.

• **VK_IMAGE_LAYOUT_FRAGMENT_DENSITY_MAP_OPTIMAL_EXT** **must** only be used as a fragment density map attachment in a **VkRenderPass**. This layout is valid only for image subresources of images created with the **VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_EXT** usage bit enabled.

The layout of each image subresource is not a state of the image subresource itself, but is rather a property of how the data in memory is organized, and thus for each mechanism of accessing an image in the API the application **must** specify a parameter or structure member that indicates which image layout the image subresource(s) are considered to be in when the image will be accessed. For transfer commands, this is a parameter to the command (see **Clear Commands** and **Copy Commands**). For use as a framebuffer attachment, this is a member in the substructures of the **VkRenderPassCreateInfo** (see **Render Pass**). For use in a descriptor set, this is a member in the **VkDescriptorImageInfo** structure (see **Descriptor Set Updates**).

### 11.4.1. Image Layout Matching Rules

At the time that any command buffer command accessing an image executes on any queue, the layouts of the image subresources that are accessed **must** all match exactly the layout specified via the API controlling those accesses, except in case of accesses to an image with a depth/stencil format performed through descriptors referring to only a single aspect of the image, where the following relaxed matching rules apply:

- Descriptors referring just to the depth aspect of a depth/stencil image only need to match in the image layout of the depth aspect, thus **VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL** and **VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL** are considered to match.

- Descriptors referring just to the stencil aspect of a depth/stencil image only need to match in the image layout of the stencil aspect, thus **VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL** and **VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL** are considered to match.

When performing a layout transition on an image subresource, the old layout value **must** either equal the current layout of the image subresource (at the time the transition executes), or else **VK_IMAGE_LAYOUT_UNDEFINED** (implying that the contents of the image subresource need not be preserved). The new layout used in a transition **must** not be **VK_IMAGE_LAYOUT_UNDEFINED** or **VK_IMAGE_LAYOUT_PREINITIALIZED**.

The image layout of each image subresource of a depth/stencil image created with **VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT** is dependent on the last sample locations used to render to the image subresource as a depth/stencil attachment, thus applications **must** provide the same sample locations that were last used to render to the given image subresource whenever a layout transition of the image subresource happens, otherwise the contents of the depth aspect of the image subresource become undefined.

In addition, depth reads from a depth/stencil attachment referring to an image subresource range of a depth/stencil image created with **VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT**
using different sample locations than what have been last used to perform depth writes to the image subresources of the same image subresource range return undefined values.

Similarly, depth writes to a depth/stencil attachment referring to an image subresource range of a depth/stencil image created with \texttt{VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT} using different sample locations than what have been last used to perform depth writes to the image subresources of the same image subresource range make the contents of the depth aspect of those image subresources undefined.

### 11.5. Image Views

Image objects are not directly accessed by pipeline shaders for reading or writing image data. Instead, \textit{image views} representing contiguous ranges of the image subresources and containing additional metadata are used for that purpose. Views \textbf{must} be created on images of compatible types, and \textbf{must} represent a valid subset of image subresources.

Image views are represented by \texttt{VkImageView} handles:

\begin{verbatim}
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkImageView)
\end{verbatim}

The types of image views that \textbf{can} be created are:

\begin{verbatim}
typedef enum VkImageViewType {
    VK_IMAGE_VIEW_TYPE_1D = 0,
    VK_IMAGE_VIEW_TYPE_2D = 1,
    VK_IMAGE_VIEW_TYPE_3D = 2,
    VK_IMAGE_VIEW_TYPE_CUBE = 3,
    VK_IMAGE_VIEW_TYPE_1D_ARRAY = 4,
    VK_IMAGE_VIEW_TYPE_2D_ARRAY = 5,
    VK_IMAGE_VIEW_TYPE_CUBE_ARRAY = 6,
} VkImageViewType;
\end{verbatim}

The exact image view type is partially implicit, based on the image's type and sample count, as well as the view creation parameters as described in the \textit{image view compatibility table} for \texttt{vkCreateImageView}. This table also shows which SPIR-V \texttt{OpTypeImage Dim} and \texttt{Arrayed} parameters correspond to each image view type.

To create an image view, call:

\begin{verbatim}
VkResult vkCreateImageView(
    VkDevice                                    device,
    const VkImageViewCreateInfo*                pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkImageView*                                pView);
\end{verbatim}

- \textit{device} is the logical device that creates the image view.

572 | Chapter 11. Resource Creation
• **pCreateInfo** is a pointer to a `VkImageViewCreateInfo` structure containing parameters to be used to create the image view.

• **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.

• **pView** is a pointer to a `VkImageView` handle in which the resulting image view object is returned.

### Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pCreateInfo** must be a valid pointer to a valid `VkImageViewCreateInfo` structure
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid `VkAllocationCallbacks` structure
- **pView** must be a valid pointer to a `VkImageView` handle

### Return Codes

**Success**
- **VK_SUCCESS**

**Failure**
- **VK_ERROR_OUT_OF_HOST_MEMORY**
- **VK_ERROR_OUT_OF_DEVICE_MEMORY**

The `VkImageViewCreateInfo` structure is defined as:

```c
typedef struct VkImageViewCreateInfo {
    VkStructureType            sType;
    const void*                pNext;
    VkImageViewCreateFlags     flags;
    VkImage                    image;
    VkImageViewType            viewType;
    VkFormat                   format;
    VkComponentMapping         components;
    VkImageSubresourceRange    subresourceRange;
} VkImageViewCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkImageViewCreateFlagBits` describing additional parameters of the image view.
- **image** is a `VkImage` on which the view will be created.
- **viewType** is a *VkImageViewType* value specifying the type of the image view.
- **format** is a *VkFormat* describing the format and type used to interpret texel blocks in the image.
- **components** is a *VkComponentMapping* specifies a remapping of color components (or of depth or stencil components after they have been converted into color components).
- **subresourceRange** is a *VkImageSubresourceRange* selecting the set of mipmap levels and array layers to be accessible to the view.

Some of the **image** creation parameters are inherited by the view. In particular, image view creation inherits the implicit parameter **usage** specifying the allowed usages of the image view that, by default, takes the value of the corresponding **usage** parameter specified in *VkImageCreateInfo* at image creation time. If the image was has a depth-stencil format and was created with a *VkImageStencilUsageCreateInfo* structure included in the **pNext** chain of *VkImageCreateInfo*, the usage is calculated based on the **aspectMask** provided:

- If **aspectMask** includes only **VK_IMAGE_ASPECT_STENCIL_BIT**, the implicit **usage** is equal to *VkImageStenclUsageCreateInfo::stencilUsage*.
- If **aspectMask** includes only **VK_IMAGE_ASPECT_DEPTH_BIT**, the implicit **usage** is equal to *VkImageCreateInfo::usage*.
- If both aspects are included in **aspectMask**, the implicit **usage** is equal to the intersection of *VkImageCreateInfo::usage* and *VkImageStenclUsageCreateInfo::stencilUsage*. The implicit **usage** can be overridden by adding a *VkImageViewUsageCreateInfo* structure to the **pNext** chain.

If **image** was created with the **VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT** flag, and if the **format** of the image is not multi-planar, **format** can be different from the image's format, but if **image** was created without the **VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT** flag and they are not equal they **must** be compatible. Image format compatibility is defined in the Format Compatibility Classes section. Views of compatible formats will have the same mapping between texel coordinates and memory locations irrespective of the **format**, with only the interpretation of the bit pattern changing.

**Note**

Values intended to be used with one view format **may** not be exactly preserved when written or read through a different format. For example, an integer value that happens to have the bit pattern of a floating point denorm or NaN **may** be flushed or canonicalized when written or read through a view with a floating point format. Similarly, a value written through a signed normalized format that has a bit pattern exactly equal to \(-2^b\) **may** be changed to \(-2^b + 1\) as described in Conversion from Normalized Fixed-Point to Floating-Point.

If **image** was created with the **VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT** flag, **format** **must** be compatible with the image's format as described above, or **must** be an uncompressed format in which case it **must** be size-compatible with the image's format, as defined for copying data between images. In this case the resulting image view's texel dimensions equal the dimensions of the selected mip level divided by the compressed texel block size and rounded up.

If the image view is to be used with a sampler which supports sampler \(Y'CbCr\) conversion, an identically defined object of type *VkSamplerYcbcrConversion* to that used to create the sampler
must be passed to \texttt{vkCreateImageView} in a \texttt{VkSamplerYcbcrConversionInfo} included in the \texttt{pNext} chain of \texttt{VkImageViewCreateInfo}. Conversely, if a \texttt{VkSamplerYcbcrConversion} object is passed to \texttt{vkCreateImageView}, an identically defined \texttt{VkSamplerYcbcrConversion} object must be used when sampling the image.

If the image has a multi-planar format and \texttt{subresourceRange.aspectMask} is \texttt{VK_IMAGE_ASPECT_COLOR_BIT}, format must be identical to the image format, and the sampler to be used with the image view must enable sampler Y′C′B′C′R conversion.

If \texttt{image} was created with the \texttt{VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT} and the image has a multi-planar format, and if \texttt{subresourceRange.aspectMask} is \texttt{VK_IMAGE_ASPECT_PLANE_0_BIT}, \texttt{VK_IMAGE_ASPECT_PLANE_1_BIT}, or \texttt{VK_IMAGE_ASPECT_PLANE_2_BIT}, format must be compatible with the corresponding plane of the image, and the sampler to be used with the image view must not enable sampler Y′C′B′C′R conversion. The width and height of the single-plane image view must be derived from the multi-planar image’s dimensions in the manner listed for plane compatibility for the plane.

Any view of an image plane will have the same mapping between texel coordinates and memory locations as used by the channels of the color aspect, subject to the formulae relating texel coordinates to lower-resolution planes as described in Chroma Reconstruction. That is, if an R or B plane has a reduced resolution relative to the G plane of the multi-planar image, the image view operates using the \((u_{\text{plane}}, v_{\text{plane}})\) unnormalized coordinates of the reduced-resolution plane, and these coordinates access the same memory locations as the \((u_{\text{color}}, v_{\text{color}})\) unnormalized coordinates of the color aspect for which chroma reconstruction operations operate on the same \((i_{\text{plane}}, j_{\text{plane}})\) coordinates.

Valid Usage

• If image was not created with VK_IMAGE_CREATE_CUBE_COMPATIBLE_BIT then viewType must not be VK_IMAGE_VIEW_TYPE_CUBE or VK_IMAGE_VIEW_TYPE_CUBE_ARRAY

• If the image cubemap arrays feature is not enabled, viewType must not be VK_IMAGE_VIEW_TYPE_CUBE_ARRAY

• If image was created with VK_IMAGE_TYPE_3D but without VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT set then viewType must not be VK_IMAGE_VIEW_TYPE_2D or VK_IMAGE_VIEW_TYPE_2D_ARRAY

• image must have been created with a usage value containing at least one of VK_IMAGE_USAGE_SAMPLED_BIT, VK_IMAGE_USAGE_STORAGE_BIT, VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT, VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT, VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT, VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV, or VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_EXT

• The format features of the resultant image view must contain at least one bit

• If usage contains VK_IMAGE_USAGE_SAMPLED_BIT, then the format features of the resultant image view must contain VK_FORMAT_FEATURE_SAMPLED_IMAGE_BIT

• If usage contains VK_IMAGE_USAGE_STORAGE_BIT, then the image view's format features must contain VK_FORMAT_FEATURE_STORAGE_IMAGE_BIT

• If usage contains VK_IMAGE_USAGE_COLOR_ATTACHMENT_BIT, then the image view's format features must contain VK_FORMAT_FEATURE_COLOR_ATTACHMENT_BIT

• If usage contains VK_IMAGE_USAGE_DEPTH_STENCIL_ATTACHMENT_BIT, then the image view's format features must contain VK_FORMAT_FEATURE_DEPTH_STENCIL_ATTACHMENT_BIT

• If usage contains VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT, then the image view's format features must contain at least one of VK_FORMAT_FEATURE_COLOR_ATTACHMENT_BIT or VK_FORMAT_FEATURE_DEPTH_STENCIL_ATTACHMENT_BIT

• subresourceRange.baseMipLevel must be less than the mipLevels specified in VkImageCreateInfo when image was created

• If subresourceRange.levelCount is not VK_REMAINING_MIP_LEVELS, subresourceRange.baseMipLevel + subresourceRange.levelCount must be less than or equal to the mipLevels specified in VkImageCreateInfo when image was created

• If image was created with usage containing VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_EXT, subresourceRange.levelCount must be 1

• If image is not a 3D image created with VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT set, or viewType is not VK_IMAGE_VIEW_TYPE_2D or VK_IMAGE_VIEW_TYPE_2D_ARRAY, subresourceRange.baseArrayLayer must be less than the arrayLayers specified in VkImageCreateInfo when image was created

• If subresourceRange.layerCount is not VK_REMAINING_ARRAY_LAYERS, image is not a 3D image created with VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT set, or viewType is not VK_IMAGE_VIEW_TYPE_2D or VK_IMAGE_VIEW_TYPE_2D_ARRAY, subresourceRange.layerCount must be non-zero and subresourceRange.baseArrayLayer + subresourceRange.layerCount must be less than or equal to the arrayLayers specified in VkImageCreateInfo when image was created
• If `image` is a 3D image created with `VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT` set, and `viewType` is `VK_IMAGE_VIEW_TYPE_2D` or `VK_IMAGE_VIEW_TYPE_2D_ARRAY`, `subresourceRange.baseArrayLayer` must be less than the depth computed from `baseMipLevel` and `extent.depth` specified in `VkImageCreateInfo` when `image` was created, according to the formula defined in `Image Miplevel Sizing`.

• If `subresourceRange.layerCount` is not `VK_REMAINING_ARRAY_LAYERS`, `image` is a 3D image created with `VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT` set, and `viewType` is `VK_IMAGE_VIEW_TYPE_2D` or `VK_IMAGE_VIEW_TYPE_2D_ARRAY`, `subresourceRange.layerCount` must be non-zero and `subresourceRange.baseArrayLayer + subresourceRange.layerCount` must be less than or equal to the depth computed from `baseMipLevel` and `extent.depth` specified in `VkImageCreateInfo` when `image` was created, according to the formula defined in `Image Miplevel Sizing`.

• If `image` was created with the `VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT` flag, but without the `VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT` flag, and if the format of the `image` is not a multi-planar format, format must be compatible with the format used to create `image`, as defined in `Format Compatibility Classes`.

• If `image` was created with the `VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT` flag, format must be compatible with, or must be an uncompressed format that is size-compatible with, the format used to create `image`.

• If `image` was created with the `VK_IMAGE_CREATE_BLOCK_TEXEL_VIEW_COMPATIBLE_BIT` flag, the `levelCount` and `layerCount` members of `subresourceRange` must both be 1.

• If a `VkImageFormatListCreateInfo` structure was included in the `pNext` chain of the `VkImageCreateInfo` structure used when creating `image` and the `viewFormatCount` field of `VkImageFormatListCreateInfo` is not zero then format must be one of the formats in `VkImageFormatListCreateInfo::pViewFormats`.

• If `image` was created with the `VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT` flag, if the format of the `image` is a multi-planar format, and if `subresourceRange.aspectMask` is one of `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT`, or `VK_IMAGE_ASPECT_PLANE_2_BIT`, then format must be compatible with the `VkFormat` for the plane of the `image` format indicated by `subresourceRange.aspectMask`, as defined in `Compatible formats of planes of multi-planar formats`.

• If `image` was not created with the `VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT` flag, or if the format of the `image` is a multi-planar format and if `subresourceRange.aspectMask` is `VK_IMAGE_ASPECT_COLOR_BIT`, format must be identical to the format used to create `image`.

• If the `pNext` chain includes a `VkSamplerYcbcrConversionInfo` structure with a `conversion` value other than `VK_NULL_HANDLE`, all members of `components` must have the value `VK_COMPONENT_SWIZZLE_IDENTITY`.

• If `image` is non-sparse then it must be bound completely and contiguously to a single `VkDeviceMemory` object.

• `subresourceRange` and `viewType` must be compatible with the image, as described in the compatibility table.

• If `image` has an external format, format must be `VK_FORMAT_UNDEFINED`.

• If `image` has an external format, the `pNext` chain must include a
**VkSamplerYcbcrConversionInfo** structure with a conversion object created with the same external format as `image`.

- If `image` has an external format, all members of components must be `VK_COMPONENT_SWIZZLE_IDENTITY`.
- If `image` was created with usage containing `VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV`, `viewType` must be `VK_IMAGE_VIEW_TYPE_2D` or `VK_IMAGE_VIEW_TYPE_2D_ARRAY`.
- If `image` was created with usage containing `VK_IMAGE_USAGE_SHADING_RATE_IMAGE_BIT_NV`, `format` must be `VK_FORMAT_R8_UINT`.
- If dynamic fragment density map feature is not enabled, `flags` must not contain `VK_IMAGE_VIEW_CREATE_FRAGMENT_DENSITY_MAP_DYNAMIC_BIT_EXT`.
- If dynamic fragment density map feature is not enabled and `image` was created with usage containing `VK_IMAGE_USAGE_FRAGMENT_DENSITY_MAP_BIT_NV, flags` must not contain any of `VK_IMAGE_CREATE_PROTECTED_BIT, VK_IMAGE_CREATE_SPARSE_BINDING_BIT, VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT, or VK_IMAGE_CREATE_SPARSE_ALIASED_BIT`.
- If the `pNext` chain includes a `VkImageViewUsageCreateInfo` structure, and `image` was not created with a `VkImageStencilUsageCreateInfo` structure included in the `pNext` chain of `VkImageCreateInfo`, its `usage` member must not include any bits that were not set in the `usage` member of the `VkImageCreateInfo` structure used to create `image`.
- If the `pNext` chain includes a `VkImageViewUsageCreateInfo` structure, `image` was created with a `VkImageStencilUsageCreateInfo` structure included in the `pNext` chain of `VkImageCreateInfo`, and `subResourceRange.aspectMask` includes `VK_IMAGE_ASPECT_STENCIL_BIT`, the `usage` member of the `VkImageViewUsageCreateInfo` instance must not include any bits that were not set in the `usage` member of the `VkImageCreateInfo` structure used to create `image`.
- If the `pNext` chain includes a `VkImageViewUsageCreateInfo` structure, `image` was created with a `VkImageStencilUsageCreateInfo` structure included in the `pNext` chain of `VkImageCreateInfo`, and `subResourceRange` does not include other than `VK_IMAGE_ASPECT_STENCIL_BIT`, the `usage` member of the `VkImageViewUsageCreateInfo` structure must not include any bits that were not set in the `usage` member of the `VkImageCreateInfo` structure used to create `image`.
- If `viewType` is `VK_IMAGE_VIEW_TYPE_CUBE` and `subresourceRange.layerCount` is not `VK_REMAINING_ARRAY_LAYERS`, `subresourceRange.layerCount` must be 6.
- If `viewType` is `VK_IMAGE_VIEW_TYPE_CUBE_ARRAY` and `subresourceRange.layerCount` is not `VK_REMAINING_ARRAY_LAYERS`, `subresourceRange.layerCount` must be a multiple of 6.
- If `viewType` is `VK_IMAGE_VIEW_TYPE_CUBE` and `subresourceRange.layerCount` is `VK_REMAINING_ARRAY_LAYERS`, the remaining number of layers must be 6.
- If `viewType` is `VK_IMAGE_VIEW_TYPE_CUBE_ARRAY` and `subresourceRange.layerCount` is `VK_REMAINING_ARRAY_LAYERS`, the remaining number of layers must be a multiple of 6.
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_IMAGE_VIEW_CREATE_INFO`
- Each `pNext` member of any structure (including this one) in the `pNext` chain must be either `NULL` or a pointer to a valid instance of `VkImageViewASTCDecodeModeEXT`, `VkImageViewUsageCreateInfo`, or `VkSamplerYcbcrConversionInfo`
- The `sType` value of each struct in the `pNext` chain must be unique
- `flags` must be a valid combination of `VkImageViewCreateFlagBits` values
- `image` must be a valid `VkImage` handle
- `viewType` must be a valid `VkImageViewType` value
- `format` must be a valid `VkFormat` value
- `components` must be a valid `VkComponentMapping` structure
- `subresourceRange` must be a valid `VkImageSubresourceRange` structure

Bits which can be set in `VkImageViewCreateInfo::flags`, specifying additional parameters of an image, are:

```c
typedef enum VkImageViewCreateFlagBits {
    VK_IMAGE_VIEW_CREATE_FRAGMENT_DENSITY_MAP_DYNAMIC_BIT_EXT = 0x00000001,
} VkImageViewCreateFlagBits;
```

- `VK_IMAGE_VIEW_CREATE_FRAGMENT_DENSITY_MAP_DYNAMIC_BIT_EXT` prohibits the implementation from accessing the fragment density map by the host during `vkCmdBeginRenderPass` as the contents are expected to change after recording

```c
typedef VkFlags VkImageViewCreateFlags;
```

`VkImageViewCreateFlags` is a bitmask type for setting a mask of zero or more `VkImageViewCreateFlagBits`.

The set of usages for the created image view can be restricted compared to the parent image’s `usage` flags by adding a `VkImageViewUsageCreateInfo` structure to the `pNext` chain of `VkImageViewCreateInfo`.

The `VkImageViewUsageCreateInfo` structure is defined as:

```c
typedef struct VkImageViewUsageCreateInfo {
    VkStructureType      sType;
    const void*          pNext;
    VkImageUsageFlags    usage;
} VkImageViewUsageCreateInfo;
```
typedef VkImageViewUsageCreateInfo VkImageViewUsageCreateInfoKHR;

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **usage** is a bitmask describing the allowed usages of the image view. See **VkImageUsageFlagBits** for a description of the supported bits.

When this structure is chained to **VkImageViewCreateInfo** the **usage** field overrides the implicit **usage** parameter inherited from image creation time and its value is used instead for the purposes of determining the valid usage conditions of **VkImageViewCreateInfo**.

### Valid Usage (Implicit)

- **sType** must be **VK_STRUCTURE_TYPE_IMAGE_VIEW_USAGE_CREATE_INFO**
- **usage** must be a valid combination of **VkImageUsageFlagBits** values
- **usage** must not be 0

The **VkImageSubresourceRange** structure is defined as:

```c
typedef struct VkImageSubresourceRange {
    VkImageAspectFlags    aspectMask;
    uint32_t              baseMipLevel;
    uint32_t              levelCount;
    uint32_t              baseArrayLayer;
    uint32_t              layerCount;
} VkImageSubresourceRange;
```

- **aspectMask** is a bitmask of **VkImageAspectFlagBits** specifying which aspect(s) of the image are included in the view.
- **baseMipLevel** is the first mipmap level accessible to the view.
- **levelCount** is the number of mipmap levels (starting from **baseMipLevel**) accessible to the view.
- **baseArrayLayer** is the first array layer accessible to the view.
- **layerCount** is the number of array layers (starting from **baseArrayLayer**) accessible to the view.

The number of mipmap levels and array layers **must** be a subset of the image subresources in the image. If an application wants to use all mip levels or layers in an image after the **baseMipLevel** or **baseArrayLayer**, it **can** set **levelCount** and **layerCount** to the special values **VK_REMAINING_MIP_LEVELS** and **VK_REMAINING_ARRAY_LAYERS** without knowing the exact number of mip levels or layers.

For cube and cube array image views, the layers of the image view starting at **baseArrayLayer** correspond to faces in the order +X, -X, +Y, -Y, +Z, -Z. For cube arrays, each set of six sequential...
layers is a single cube, so the number of cube maps in a cube map array view is \( \text{layerCount} / 6 \), and image array layer \((\text{baseArrayLayer} + i)\) is face index \((i \mod 6)\) of cube \(i / 6\). If the number of layers in the view, whether set explicitly in \text{layerCount} or implied by \text{VK_REMAINING_ARRAY_LAYERS}, is not a multiple of 6, the last cube map in the array must not be accessed.

\[ \text{aspectMask} \text{ must } be \text{ only } \text{VK_IMAGE_ASPECT_COLOR_BIT}, \text{VK_IMAGE_ASPECT_DEPTH_BIT} \text{ or } \text{VK_IMAGE_ASPECT_STENCIL_BIT} \text{ if format is a color, depth-only or stencil-only format, respectively, except if format is a multi-planar format. If using a depth/stencil format with both depth and stencil components, aspectMask must include at least one of VK_IMAGE_ASPECT_DEPTH_BIT and VK_IMAGE_ASPECT_STENCIL_BIT, and can include both.} \]

When the \text{VkImageSubresourceRange} structure is used to select a subset of the slices of a 3D image's mip level in order to create a 2D or 2D array image view of a 3D image created with \text{VK_IMAGE_CREATE_2D_ARRAY_COMPATIBLE_BIT}, \text{baseArrayLayer} and \text{layerCount} specify the first slice index and the number of slices to include in the created image view. Such an image view can be used as a framebuffer attachment that refers only to the specified range of slices of the selected mip level. However, any layout transitions performed on such an attachment view during a render pass instance still apply to the entire subresource referenced which includes all the slices of the selected mip level.

When using an image view of a depth/stencil image to populate a descriptor set (e.g. for sampling in the shader, or for use as an input attachment), the \text{aspectMask} must only include one bit and selects whether the image view is used for depth reads (i.e. using a floating-point sampler or input attachment in the shader) or stencil reads (i.e. using an unsigned integer sampler or input attachment in the shader). When an image view of a depth/stencil image is used as a depth/stencil framebuffer attachment, the \text{aspectMask} is ignored and both depth and stencil image subresources are used.

The \text{VkComponentMapping components} member describes a remapping from components of the image to components of the vector returned by shader image instructions. This remapping must be identity for storage image descriptors, input attachment descriptors, framebuffer attachments, and any \text{VkImageView} used with a combined image sampler that enables sampler \(Y'\text{C}_b\text{C}_r\) conversion.

When creating a \text{VkImageView}, if sampler \(Y'\text{C}_b\text{C}_r\) conversion is enabled in the sampler, the \text{aspectMask} of a \text{subresourceRange} used by the \text{VkImageView} must be \text{VK_IMAGE_ASPECT_COLOR_BIT}.

When creating a \text{VkImageView}, if sampler \(Y'\text{C}_b\text{C}_r\) conversion is not enabled in the sampler and the image format is multi-planar, the image must have been created with \text{VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT}, and the \text{aspectMask} of the \text{VkImageView}'s \text{subresourceRange} must be \text{VK_IMAGE_ASPECT_PLANE_0_BIT}, \text{VK_IMAGE_ASPECT_PLANE_1_BIT} or \text{VK_IMAGE_ASPECT_PLANE_2_BIT}.
Valid Usage

- If `levelCount` is not `VK_REMAINING_MIP_LEVELS`, it **must** be greater than 0
- If `layerCount` is not `VK_REMAINING_ARRAY_LAYERS`, it **must** be greater than 0
- If `aspectMask` includes `VK_IMAGE_ASPECT_COLOR_BIT`, then it **must** not include any of `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT`, or `VK_IMAGE_ASPECT_PLANE_2_BIT`
- `aspectMask` **must** not include `VK_IMAGE_ASPECT_MEMORY_PLANE_i_BIT_EXT` for any index `i`

Valid Usage (Implicit)

- `aspectMask` **must** be a valid combination of `VkImageAspectFlagBits` values
- `aspectMask` **must** not be 0

Bits which **can** be set in an aspect mask to specify aspects of an image for purposes such as identifying a subresource, are:

```c
typedef enum VkImageAspectFlagBits {
    VK_IMAGE_ASPECT_COLOR_BIT = 0x00000001,
    VK_IMAGE_ASPECT_DEPTH_BIT = 0x00000002,
    VK_IMAGE_ASPECT_STENCIL_BIT = 0x00000004,
    VK_IMAGE_ASPECT_METADATA_BIT = 0x00000008,
    VK_IMAGE_ASPECT_PLANE_0_BIT = 0x00000010,
    VK_IMAGE_ASPECT_PLANE_1_BIT = 0x00000020,
    VK_IMAGE_ASPECT_PLANE_2_BIT = 0x00000040,
    VK_IMAGE_ASPECT_PLANE_0_BIT_KHR = VK_IMAGE_ASPECT_PLANE_0_BIT,
    VK_IMAGE_ASPECT_PLANE_1_BIT_KHR = VK_IMAGE_ASPECT_PLANE_1_BIT,
    VK_IMAGE_ASPECT_PLANE_2_BIT_KHR = VK_IMAGE_ASPECT_PLANE_2_BIT,
} VkImageAspectFlagBits;
```

- `VK_IMAGE_ASPECT_COLOR_BIT` specifies the color aspect.
- `VK_IMAGE_ASPECT_DEPTH_BIT` specifies the depth aspect.
- `VK_IMAGE_ASPECT_STENCIL_BIT` specifies the stencil aspect.
- `VK_IMAGE_ASPECT_METADATA_BIT` specifies the metadata aspect, used for sparse resource operations.
- `VK_IMAGE_ASPECT_PLANE_0_BIT` specifies plane 0 of a *multi-planar* image format.
- `VK_IMAGE_ASPECT_PLANE_1_BIT` specifies plane 1 of a *multi-planar* image format.
- `VK_IMAGE_ASPECT_PLANE_2_BIT` specifies plane 2 of a *multi-planar* image format.
• VK_IMAGE_ASPECT_MEMORY_PLANE_0_BIT_EXT specifies memory plane 0.
• VK_IMAGE_ASPECT_MEMORY_PLANE_1_BIT_EXT specifies memory plane 1.
• VK_IMAGE_ASPECT_MEMORY_PLANE_2_BIT_EXT specifies memory plane 2.
• VK_IMAGE_ASPECT_MEMORY_PLANE_3_BIT_EXT specifies memory plane 3.

```c
typedef VkFlags VkImageAspectFlags;
```

VkImageAspectFlags is a bitmask type for setting a mask of zero or more VkImageAspectFlagBits.

The VkComponentMapping structure is defined as:

```c
typedef struct VkComponentMapping {
    VkComponentSwizzle r;
    VkComponentSwizzle g;
    VkComponentSwizzle b;
    VkComponentSwizzle a;
} VkComponentMapping;
```

• r is a VkComponentSwizzle specifying the component value placed in the R component of the output vector.
• g is a VkComponentSwizzle specifying the component value placed in the G component of the output vector.
• b is a VkComponentSwizzle specifying the component value placed in the B component of the output vector.
• a is a VkComponentSwizzle specifying the component value placed in the A component of the output vector.

```
Valid Usage (Implicit)
```

• r must be a valid VkComponentSwizzle value
• g must be a valid VkComponentSwizzle value
• b must be a valid VkComponentSwizzle value
• a must be a valid VkComponentSwizzle value

Possible values of the members of VkComponentMapping, specifying the component values placed in each component of the output vector, are:
typedef enum VkComponentSwizzle {
    VK_COMPONENT_SWIZZLE_IDENTITY = 0,
    VK_COMPONENT_SWIZZLE_ZERO = 1,
    VK_COMPONENT_SWIZZLE_ONE = 2,
    VK_COMPONENT_SWIZZLE_R = 3,
    VK_COMPONENT_SWIZZLE_G = 4,
    VK_COMPONENT_SWIZZLE_B = 5,
    VK_COMPONENT_SWIZZLE_A = 6,
} VkComponentSwizzle;

• **VK_COMPONENT_SWIZZLE_IDENTITY** specifies that the component is set to the identity swizzle.
• **VK_COMPONENT_SWIZZLE_ZERO** specifies that the component is set to zero.
• **VK_COMPONENT_SWIZZLE_ONE** specifies that the component is set to either 1 or 1.0, depending on whether the type of the image view format is integer or floating-point respectively, as determined by the Format Definition section for each VkFormat.
• **VK_COMPONENT_SWIZZLE_R** specifies that the component is set to the value of the R component of the image.
• **VK_COMPONENT_SWIZZLE_G** specifies that the component is set to the value of the G component of the image.
• **VK_COMPONENT_SWIZZLE_B** specifies that the component is set to the value of the B component of the image.
• **VK_COMPONENT_SWIZZLE_A** specifies that the component is set to the value of the A component of the image.

Setting the identity swizzle on a component is equivalent to setting the identity mapping on that component. That is:

*Table 16. Component Mappings Equivalent To VK_COMPONENT_SWIZZLE_IDENTITY*

<table>
<thead>
<tr>
<th>Component</th>
<th>Identity Mapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>components.r</td>
<td>VK_COMPONENT_SWIZZLE_R</td>

<td>VK_COMPONENT_SWIZZLE_B</td>
</tr>
<tr>
<td>components.a</td>
<td>VK_COMPONENT_SWIZZLE_A</td>
</tr>
</tbody>
</table>

If the pNext list includes a VkImageViewASTCDecodeModeEXT structure, then that structure includes a parameter specifying the decode mode for image views using ASTC compressed formats.

The VkImageViewASTCDecodeModeEXT structure is defined as:
typedef struct VkImageViewASTCDecodeModeEXT {
    VkStructureType    sType;
    const void*        pNext;
    VkFormat           decodeMode;
} VkImageViewASTCDecodeModeEXT;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `decodeMode` is the intermediate format used to decode ASTC compressed formats.

### Valid Usage

- `decodeMode` **must** be one of `VK_FORMAT_R16G16B16A16_SFLOAT`, `VK_FORMAT_R8G8B8A8_UNORM`, or `VK_FORMAT_E5B9G9R9_UFLOAT_PACK32`.
- If the `decodeModeSharedExponent` feature is not enabled, `decodeMode` **must** not be `VK_FORMAT_E5B9G9R9_UFLOAT_PACK32`.
- If `decodeMode` is `VK_FORMAT_R8G8B8A8_UNORM` the image view **must** not include blocks using any of the ASTC HDR modes.
- `format` of the image view **must** be one of `VK_FORMAT_ASTC_4x4_UNORM_BLOCK`, `VK_FORMAT_ASTC_5x4_SRGB_BLOCK`, `VK_FORMAT_ASTC_5x5_SRGB_BLOCK`, `VK_FORMAT_ASTC_6x5_SRGB_BLOCK`, `VK_FORMAT_ASTC_6x6_SRGB_BLOCK`, `VK_FORMAT_ASTC_8x5_SRGB_BLOCK`, `VK_FORMAT_ASTC_8x6_SRGB_BLOCK`, `VK_FORMAT_ASTC_8x8_SRGB_BLOCK`, `VK_FORMAT_ASTC_10x5_SRGB_BLOCK`, `VK_FORMAT_ASTC_10x6_SRGB_BLOCK`, `VK_FORMAT_ASTC_10x8_SRGB_BLOCK`, `VK_FORMAT_ASTC_10x10_SRGB_BLOCK`, `VK_FORMAT_ASTC_12x10_SRGB_BLOCK`, `VK_FORMAT_ASTC_12x12_SRGB_BLOCK`.

If `format` uses sRGB encoding then the `decodeMode` has no effect.

### Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_IMAGE_VIEW_ASTC_DECODE_MODE_EXT`.
- `decodeMode` **must** be a valid `VkFormat` value.

To destroy an image view, call:

```c
void vkDestroyImageView(
    VkDevice                                    device,
    VkImageView                                 imageView,
    const VkAllocationCallbacks*                pAllocator);
```

- **device** is the logical device that destroys the image view.
- **imageView** is the image view to destroy.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.

### Valid Usage

- All submitted commands that refer to **imageView** must have completed execution
- If **VkAllocationCallbacks** were provided when **imageView** was created, a compatible set of callbacks must be provided here
- If no **VkAllocationCallbacks** were provided when **imageView** was created, **pAllocator** must be NULL

### Valid Usage (Implicit)

- **device** must be a valid **VkDevice** handle
- If **imageView** is not **VK_NULL_HANDLE**, **imageView** must be a valid **VkImageView** handle
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid **VkAllocationCallbacks** structure
- If **imageView** is a valid handle, it must have been created, allocated, or retrieved from **device**

### Host Synchronization

- Host access to **imageView** must be externally synchronized

To get the handle for an image view, call:

```c
uint32_t vkGetImageViewHandleNVX(
    VkDevice                                    device,
    const VkImageViewHandleInfoNVX*             pInfo);
```

- **device** is the logical device that owns the image view.
- **pInfo** describes the image view to query and type of handle.
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pInfo** must be a valid pointer to a valid `VkImageViewHandleInfoNVX` structure

The `VkImageViewHandleInfoNVX` structure is defined as:

```c
typedef struct VkImageViewHandleInfoNVX {
    VkStructureType     sType;
    const void*         pNext;
    VkImageView         imageView;
    VkDescriptorType    descriptorType;
    VkSampler           sampler;
} VkImageViewHandleInfoNVX;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `imageView` is the image view to query.
- `descriptorType` is the type of descriptor for which to query a handle.
- `sampler` is the sampler to combine with the image view when generating the handle.

Valid Usage

- `descriptorType` must be `VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE`, `VK_DESCRIPTOR_TYPE_STORAGE_IMAGE`, or `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`
- `sampler` must be a valid `VkSampler` if `descriptorType` is `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`
- If `descriptorType` is `VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE` or `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`, the image that `imageView` was created from must have been created with the `VK_IMAGE_USAGE_SAMPLED_BIT` usage bit set
- If `descriptorType` is `VK_DESCRIPTOR_TYPE_STORAGE_IMAGE`, the image that `imageView` was created from must have been created with the `VK_IMAGE_USAGE_STORAGE_BIT` usage bit set
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_IMAGE_VIEW_HANDLE_INFO_NVX`
- `pNext` must be `NULL`
- `imageView` must be a valid `VkImageView` handle
- `descriptorType` must be a valid `VkDescriptorType` value
- If `sampler` is not `VK_NULL_HANDLE`, `sampler` must be a valid `VkSampler` handle
- Both of `imageView`, and `sampler` that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`

To get the device address for an image view, call:

```c
VkResult vkGetImageViewAddressNVX(
    VkDevice                                    device,
    VkImageView                                 imageView,
    VkImageViewAddressPropertiesNVX*            pProperties);
```

- `device` is the logical device that owns the image view.
- `imageView` is a handle to the image view.
- `pProperties` contains the device address and size when the call returns.

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `imageView` must be a valid `VkImageView` handle
- `pProperties` must be a valid pointer to a `VkImageViewAddressPropertiesNVX` structure
- `imageView` must have been created, allocated, or retrieved from `device`

Return Codes

**Success**
- `VK_SUCCESS`

**Failure**
- `VK_ERROR_UNKNOWN`

The `VkImageViewAddressPropertiesNVX` structure is defined as:
typedef struct VkImageViewAddressPropertiesNVX {
    VkStructureType       sType;
    void*                  pNext;
    VkDeviceAddress        deviceAddress;
    VkDeviceSize           size;
} VkImageViewAddressPropertiesNVX;

- \texttt{sType} is the type of this structure.
- \texttt{pNext} is \texttt{NULL} or a pointer to an extension-specific structure.
- \texttt{deviceAddress} is the device address of the image view.
- \texttt{size} is the size in bytes of the image view device memory.

### Valid Usage (Implicit)

- \texttt{sType} \textbf{must} be \texttt{VK_STRUCTURE_TYPE_IMAGE_VIEW_ADDRESS_PROPERTIES_NVX}
- \texttt{pNext} \textbf{must} be \texttt{NULL}

#### 11.5.1. Image View Format Features

Valid uses of a \texttt{VkImageView} \textbf{may} depend on the image view's \textit{format features}, defined below. Such constraints are documented in the affected valid usage statement.

- If \texttt{VkImageViewCreateInfo::image} was created with \texttt{VK_IMAGE_TILING_LINEAR}, then the image view's set of \textit{format features} is the value of \texttt{VkFormatProperties::linearTilingFeatures} found by calling \texttt{vkGetPhysicalDeviceFormatProperties} on the same \texttt{format} as \texttt{VkImageViewCreateInfo::format}.

- If \texttt{VkImageViewCreateInfo::image} was created with \texttt{VK_IMAGE_TILING_OPTIMAL}, but without an Android hardware buffer external format, then the image view's set of \textit{format features} is the value of \texttt{VkFormatProperties::optimalTilingFeatures} found by calling \texttt{vkGetPhysicalDeviceFormatProperties} on the same \texttt{format} as \texttt{VkImageViewCreateInfo::format}.

- If \texttt{VkImageViewCreateInfo::image} was created with an Android hardware buffer external format, then the image view's set of \textit{format features} is the value of \texttt{VkAndroidHardwareBufferFormatPropertiesANDROID::formatFeatures} found by calling \texttt{vkGetAndroidHardwareBufferPropertiesANDROID} on the Android hardware buffer that was imported to the \texttt{VkDeviceMemory} to which the \texttt{VkImageViewCreateInfo::image} is bound.

- If \texttt{VkImageViewCreateInfo::image} was created with \texttt{VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT}, then:
  - The image's DRM format modifier is the value of \texttt{VkImageDrmFormatModifierListCreateInfoEXT::drmFormatModifier} found by calling \texttt{vkGetImageDrmFormatModifierPropertiesEXT}.
  - Let \texttt{VkDrmFormatModifierPropertiesListEXT::pDrmFormatModifierProperties} be the array found by calling \texttt{vkGetPhysicalDeviceFormatProperties2} on the same \texttt{format} as \texttt{VkImageViewCreateInfo::format}.
Let \texttt{VkDrmFormatModifierPropertiesEXT\ prop} be an array element whose \texttt{drmFormatModifier\ member} is the value of the image’s DRM format modifier.

Then the image view’s set of \textit{format features} is the value of taking the bitwise intersection, over the collected \texttt{prop::drmFormatModifierTilingFeatures}.

11.6. Resource Memory Association

Resources are initially created as \textit{virtual allocations} with no backing memory. Device memory is allocated separately (see Device Memory) and then associated with the resource. This association is done differently for sparse and non-sparse resources.

Resources created with any of the sparse creation flags are considered sparse resources. Resources created without these flags are non-sparse. The details on resource memory association for sparse resources is described in Sparse Resources.

Non-sparse resources \textbf{must} be bound completely and contiguously to a single \texttt{VkDeviceMemory\ object} before the resource is passed as a parameter to any of the following operations:

- creating image or buffer views
- updating descriptor sets
- recording commands in a command buffer

Once bound, the memory binding is immutable for the lifetime of the resource.

In a logical device representing more than one physical device, buffer and image resources exist on all physical devices but \textbf{can} be bound to memory differently on each. Each such replicated resource is an \textit{instance} of the resource. For sparse resources, each instance \textbf{can} be bound to memory arbitrarily differently. For non-sparse resources, each instance \textbf{can} either be bound to the local or a peer instance of the memory, or for images \textbf{can} be bound to rectangular regions from the local and/or peer instances. When a resource is used in a descriptor set, each physical device interprets the descriptor according to its own instance’s binding to memory.

\textit{Note}

There are no new copy commands to transfer data between physical devices. Instead, an application \textbf{can} create a resource with a peer mapping and use it as the source or destination of a transfer command executed by a single physical device to copy the data from one physical device to another.

To determine the memory requirements for a buffer resource, call:

\begin{verbatim}
void vkGetBufferMemoryRequirements(
    VkDevice device,
    VkBuffer buffer,
    VkMemoryRequirements* pMemoryRequirements);
\end{verbatim}

- \texttt{device} is the logical device that owns the buffer.
• buffer is the buffer to query.
• pMemoryRequirements is a pointer to a VkMemoryRequirements structure in which the memory requirements of the buffer object are returned.

Valid Usage

• If buffer was created with the VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID external memory handle type, then buffer must be bound to memory

Valid Usage (Implicit)

• device must be a valid VkDevice handle
• buffer must be a valid VkBuffer handle
• pMemoryRequirements must be a valid pointer to a VkMemoryRequirements structure
• buffer must have been created, allocated, or retrieved from device

To determine the memory requirements for an image resource which is not created with the VK_IMAGE_CREATE_DISJOINT_BIT flag set, call:

```c
void vkGetImageMemoryRequirements(
    VkDevice device,
    VkImage image,
    VkMemoryRequirements* pMemoryRequirements);
```

• device is the logical device that owns the image.
• image is the image to query.
• pMemoryRequirements is a pointer to a VkMemoryRequirements structure in which the memory requirements of the image object are returned.

Valid Usage

• image must not have been created with the VK_IMAGE_CREATE_DISJOINT_BIT flag set
• If image was created with the VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID external memory handle type, then image must be bound to memory
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **image** must be a valid `VkImage` handle
- **pMemoryRequirements** must be a valid pointer to a `VkMemoryRequirements` structure
- **image** must have been created, allocated, or retrieved from **device**

The `VkMemoryRequirements` structure is defined as:

```c
typedef struct VkMemoryRequirements {
    VkDeviceSize    size;
    VkDeviceSize    alignment;
    uint32_t        memoryTypeBits;
} VkMemoryRequirements;
```

- **size** is the size, in bytes, of the memory allocation **required** for the resource.
- **alignment** is the alignment, in bytes, of the offset within the allocation **required** for the resource.
- **memoryTypeBits** is a bitmask and contains one bit set for every supported memory type for the resource. Bit $i$ is set if and only if the memory type $i$ in the `VkPhysicalDeviceMemoryProperties` structure for the physical device is supported for the resource.

The precise size of images that will be bound to external Android hardware buffer memory is unknown until the memory has been imported or allocated, so applications must not call `vkGetImageMemoryRequirements` with such an image before it has been bound to memory. When importing Android hardware buffer memory, the `allocationSize` can be determined by calling `vkGetAndroidHardwareBufferPropertiesANDROID`. When allocating new memory for an image that can be exported to an Android hardware buffer, the memory's `allocationSize` **must** be zero; the actual size will be determined by the dedicated image's parameters. After the memory has been allocated, the amount of space allocated from the memory's heap can be obtained by getting the image's memory requirements or by calling `vkGetAndroidHardwareBufferPropertiesANDROID` with the Android hardware buffer exported from the memory.

The implementation guarantees certain properties about the memory requirements returned by `vkGetBufferMemoryRequirements2`, `vkGetImageMemoryRequirements2`, `vkGetBufferMemoryRequirements` and `vkGetImageMemoryRequirements`:

- The `memoryTypeBits` member always contains at least one bit set.
- If `buffer` is a `VkBuffer` not created with the `VK_BUFFER_CREATE_SPARSE_BINDING_BIT` bit set, or if `image` is linear image, then the `memoryTypeBits` member always contains at least one bit set corresponding to a `VkMemoryType` with a `propertyFlags` that has both the `VK_MEMORY_PROPERTY_HOST_VISIBLE_BIT` bit and the `VK_MEMORY_PROPERTY_HOST_COHERENT_BIT` bit set. In other words, mappable coherent memory can always be attached to these objects.
- If `buffer` was created with `VkExternalMemoryBufferCreateInfo::handleTypes` set to 0 or `image`
was created with `VkExternalMemoryImageCreateInfo::handleTypes` set to 0, the `memoryTypeBits` member always contains at least one bit set corresponding to a `VkMemoryType` with a `propertyFlags` that has the `VK_MEMORY_PROPERTY_DEVICE_LOCAL_BIT` bit set.

- The `memoryTypeBits` member is identical for all `VkBuffer` objects created with the same value for the `flags` and `usage` members in the `VkBufferCreateInfo` structure and the `handleTypes` member of the `VkExternalMemoryBufferCreateInfo` structure passed to `vkCreateBuffer`. Further, if `usage1` and `usage2` of type `VkBufferUsageFlags` are such that the bits set in `usage1` are a subset of the bits set in `usage2`, and they have the same `flags` and `VkExternalMemoryBufferCreateInfo::handleTypes`, then the bits set in `memoryTypeBits` returned for `usage1` must be a subset of the bits set in `memoryTypeBits` returned for `usage2`, for all values of `flags`.

- The `alignment` member is a power of two.

- The `alignment` member is identical for all `VkBuffer` objects created with the same combination of values for the `usage` and `flags` members in the `VkBufferCreateInfo` structure passed to `vkCreateBuffer`.

- The `alignment` member satisfies the buffer descriptor offset alignment requirements associated with the `VkBuffer`’s `usage`:
  - If `usage` included `VK_BUFFER_USAGE_UNIFORM_TEXEL_BUFFER_BIT` or `VK_BUFFER_USAGE_STORAGE_TEXEL_BUFFER_BIT`, `alignment` must be an integer multiple of `VkPhysicalDeviceLimits::minTexelBufferOffsetAlignment`.
  - If `usage` included `VK_BUFFER_USAGE_UNIFORM_BUFFER_BIT`, `alignment` must be an integer multiple of `VkPhysicalDeviceLimits::minUniformBufferOffsetAlignment`.
  - If `usage` included `VK_BUFFER_USAGE_STORAGE_BUFFER_BIT`, `alignment` must be an integer multiple of `VkPhysicalDeviceLimits::minStorageBufferOffsetAlignment`.

- For images created with a color format, the `memoryTypeBits` member is identical for all `VkImage` objects created with the same combination of values for the `tiling` member, the `VK_IMAGE_CREATE_SPARSE_BINDING_BIT` bit of the `flags` member, the `VK_IMAGE_CREATE_SPLIT_INSTANCE_BIND_REGIONS_BIT` bit of the `flags` member, `handleTypes` member of `VkExternalMemoryImageCreateInfo`, and the `VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT` of the `usage` member in the `VkImageCreateInfo` structure passed to `vkCreateImage`.

- For images created with a depth/stencil format, the `memoryTypeBits` member is identical for all `VkImage` objects created with the same combination of values for the `format` member, the `tiling` member, the `VK_IMAGE_CREATE_SPARSE_BINDING_BIT` bit of the `flags` member, the `VK_IMAGE_CREATE_SPLIT_INSTANCE_BIND_REGIONS_BIT` bit of the `flags` member, `handleTypes` member of `VkExternalMemoryImageCreateInfo`, and the `VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT` of the `usage` member in the `VkImageCreateInfo` structure passed to `vkCreateImage`.

- If the memory requirements are for a `VkImage`, the `memoryTypeBits` member must not refer to a `VkMemoryType` with a `propertyFlags` that has the `VK_MEMORY_PROPERTY_LAZILY_ALLOCATED_BIT` bit set if the image did not have `VK_IMAGE_USAGE_TRANSIENT_ATTACHMENT_BIT` bit set in the `usage` member of the `VkImageCreateInfo` structure passed to `vkCreateImage`.

- If the memory requirements are for a `VkBuffer`, the `memoryTypeBits` member must not refer to a `VkMemoryType` with a `propertyFlags` that has the `VK_MEMORY_PROPERTY_LAZILY_ALLOCATED_BIT` bit set.
The implication of this requirement is that lazily allocated memory is disallowed for buffers in all cases.

- The `size` member is identical for all `VkBuffer` objects created with the same combination of creation parameters specified in `VkBufferCreateInfo` and its `pNext` chain.
- The `size` member is identical for all `VkImage` objects created with the same combination of creation parameters specified in `VkImageCreateInfo` and its `pNext` chain.

This, however, does not imply that they interpret the contents of the bound memory identically with each other. That additional guarantee, however, can be explicitly requested using `VK_IMAGE_CREATE_ALIAS_BIT`.

To determine the memory requirements for a buffer resource, call:

```c
void vkGetBufferMemoryRequirements2KHR(
    VkDevice                                    device,                        
    const VkBufferMemoryRequirementsInfo2*      pInfo,                        
    VkMemoryRequirements2*                      pMemoryRequirements);
```

- `device` is the logical device that owns the buffer.
- `pInfo` is a pointer to a `VkBufferMemoryRequirementsInfo2` structure containing parameters required for the memory requirements query.
- `pMemoryRequirements` is a pointer to a `VkMemoryRequirements2` structure in which the memory requirements of the buffer object are returned.

### Valid Usage (Implicit)

- `device` **must** be a valid `VkDevice` handle
- `pInfo` **must** be a valid pointer to a valid `VkBufferMemoryRequirementsInfo2` structure
- `pMemoryRequirements` **must** be a valid pointer to a `VkMemoryRequirements2` structure

The `VkBufferMemoryRequirementsInfo2` structure is defined as:

```c
typedef struct VkBufferMemoryRequirementsInfo2 {
    VkStructureType    sType;
    const void*        pNext;
    VkBuffer           buffer;
} VkBufferMemoryRequirementsInfo2;
```

or the equivalent
typedef VkBufferMemoryRequirementsInfo2 VkBufferMemoryRequirementsInfo2KHR;

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `buffer` is the buffer to query.

### Valid Usage

- If `buffer` was created with the `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID` external memory handle type, then `buffer must` be bound to memory.

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_BUFFER_MEMORY_REQUIREMENTS_INFO_2`
- `pNext` must be NULL
- `buffer` must be a valid `VkBuffer` handle

To determine the memory requirements for an image resource, call:

```c
void vkGetImageMemoryRequirements2KHR(
    VkDevice device, 
    const VkImageMemoryRequirementsInfo2* pInfo, 
    VkMemoryRequirements2* pMemoryRequirements);
```

- `device` is the logical device that owns the image.
- `pInfo` is a pointer to a `VkImageMemoryRequirementsInfo2` structure containing parameters required for the memory requirements query.
- `pMemoryRequirements` is a pointer to a `VkMemoryRequirements2` structure in which the memory requirements of the image object are returned.

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pInfo` must be a valid pointer to a valid `VkImageMemoryRequirementsInfo2` structure
- `pMemoryRequirements` must be a valid pointer to a `VkMemoryRequirements2` structure

The `VkImageMemoryRequirementsInfo2` structure is defined as:
typedef struct VkImageMemoryRequirementsInfo2 {
    VkStructureType   sType;
    const void*       pNext;
    VkImage           image;
} VkImageMemoryRequirementsInfo2;

or the equivalent

typedef VkImageMemoryRequirementsInfo2 VkImageMemoryRequirementsInfo2KHR;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `image` is the image to query.

**Valid Usage**

- If `image` was created with a *multi-planar* format and the `VK_IMAGE_CREATE_DISJOINT_BIT` flag, there **must** be a `VkImagePlaneMemoryRequirementsInfo` included in the `pNext` chain of the `VkImageMemoryRequirementsInfo2` structure.

- If `image` was created with `VK_IMAGE_CREATE_DISJOINT_BIT` and with `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then there **must** be a `VkImagePlaneMemoryRequirementsInfo` included in the `pNext` chain of the `VkImageMemoryRequirementsInfo2` structure.

- If `image` was not created with the `VK_IMAGE_CREATE_DISJOINT_BIT` flag, there **must** not be a `VkImagePlaneMemoryRequirementsInfo` included in the `pNext` chain of the `VkImageMemoryRequirementsInfo2` structure.

- If `image` was created with a single-plane format and with any tiling other than `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then there **must** not be a `VkImagePlaneMemoryRequirementsInfo` included in the `pNext` chain of the `VkImageMemoryRequirementsInfo2` structure.

- If `image` was created with the `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BITANDROID` external memory handle type, then `image` **must** be bound to memory.
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_IMAGE_MEMORY_REQUIREMENTS_INFO_2`
- `pNext` must be `NULL` or a pointer to a valid instance of `VkImagePlaneMemoryRequirementsInfo`
- The `sType` value of each struct in the `pNext` chain must be unique
- `image` must be a valid `VkImage` handle

To determine the memory requirements for a plane of a disjoint image, add a `VkImagePlaneMemoryRequirementsInfo` structure to the `pNext` chain of the `VkImageMemoryRequirementsInfo2` structure.

The `VkImagePlaneMemoryRequirementsInfo` structure is defined as:

```c
typedef struct VkImagePlaneMemoryRequirementsInfo {
    VkStructureType          sType;
    const void*              pNext;
    VkImageAspectFlagBits    planeAspect;
} VkImagePlaneMemoryRequirementsInfo;
```

or the equivalent

```c
typedef VkImagePlaneMemoryRequirementsInfo VkImagePlaneMemoryRequirementsInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `planeAspect` is the aspect corresponding to the image plane to query.

Valid Usage

- If the image's tiling is `VK_IMAGE_TILING_LINEAR` or `VK_IMAGE_TILING_OPTIMAL`, then `planeAspect` must be a single valid `format plane` for the image (that is, for a two-plane image `planeAspect` must be `VK_IMAGE_ASPECT_PLANE_0_BIT` or `VK_IMAGE_ASPECT_PLANE_1_BIT`, and for a three-plane image `planeAspect` must be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT` or `VK_IMAGE_ASPECT_PLANE_2_BIT`)
- If the image's tiling is `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then `planeAspect` must be a single valid `memory plane` for the image (that is, `aspectMask` must specify a plane index that is less than the `VkDrmFormatModifierPropertiesEXT::drmFormatModifierPlaneCount` associated with the image's format and `VkImageDrmFormatModifierPropertiesEXT::drmFormatModifier`)
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_IMAGE_PLANE_MEMORY_REQUIREMENTS_INFO`
- **planeAspect** must be a valid `VkImageAspectFlagBits` value

The `VkMemoryRequirements2` structure is defined as:

```c
typedef struct VkMemoryRequirements2 {
    VkStructureType         sType;
    void*                   pNext;
    VkMemoryRequirements    memoryRequirements;
} VkMemoryRequirements2;
```

or the equivalent

```c
typedef VkMemoryRequirements2 VkMemoryRequirements2KHR;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **memoryRequirements** is a `VkMemoryRequirements` structure describing the memory requirements of the resource.

Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_MEMORY_REQUIREMENTS_2`
- **pNext** must be `NULL` or a pointer to a valid instance of `VkMemoryDedicatedRequirements`
- The **sType** value of each struct in the **pNext** chain must be unique

To determine the dedicated allocation requirements of a buffer or image resource, add a `VkMemoryDedicatedRequirements` structure to the **pNext** chain of the `VkMemoryRequirements2` structure passed as the **pMemoryRequirements** parameter of `vkGetBufferMemoryRequirements2` or `vkGetImageMemoryRequirements2`.

The `VkMemoryDedicatedRequirements` structure is defined as:

```c
typedef struct VkMemoryDedicatedRequirements {
    VkStructureType    sType;
    void*              pNext;
    VkBool32           prefersDedicatedAllocation;
    VkBool32           requiresDedicatedAllocation;
} VkMemoryDedicatedRequirements;
```
typedef VkMemoryDedicatedRequirements VkMemoryDedicatedRequirementsKHR;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• prefersDedicatedAllocation specifies that the implementation would prefer a dedicated allocation for this resource. The application is still free to suballocate the resource but it may get better performance if a dedicated allocation is used.
• requiresDedicatedAllocation specifies that a dedicated allocation is required for this resource.

When the implementation sets requiresDedicatedAllocation to VK_TRUE, it must also set prefersDedicatedAllocation to VK_TRUE.

If the VkMemoryDedicatedRequirements structure is included in the pNext chain of the VkMemoryRequirements2 structure passed as the pMemoryRequirements parameter of a vkGetBufferMemoryRequirements2 call, requiresDedicatedAllocation may be VK_TRUE under one of the following conditions:

• The pNext chain of VkBufferCreateInfo for the call to vkCreateBuffer used to create the buffer being queried included a VkExternalMemoryBufferCreateInfo structure, and any of the handle types specified in VkExternalMemoryBufferCreateInfo::handleTypes requires dedicated allocation, as reported by vkGetPhysicalDeviceExternalBufferProperties in VkExternalBufferProperties::externalMemoryProperties.externalMemoryFeatures, the requiresDedicatedAllocation field will be set to VK_TRUE.

In all other cases, requiresDedicatedAllocation must be set to VK_FALSE by the implementation whenever a VkMemoryDedicatedRequirements structure is included in the pNext chain of the VkMemoryRequirements2 structure passed to a call to vkGetBufferMemoryRequirements2.

If the VkMemoryDedicatedRequirements structure is included in the pNext chain of the VkMemoryRequirements2 structure passed as the pMemoryRequirements parameter of a vkGetBufferMemoryRequirements2 call and VK_BUFFER_CREATE_SPARSE_BINDING_BIT was set in VkBufferCreateInfo::flags when buffer was created then the implementation must set both prefersDedicatedAllocation and requiresDedicatedAllocation to VK_FALSE.

If the VkMemoryDedicatedRequirements structure is included in the pNext chain of the VkMemoryRequirements2 structure passed as the pMemoryRequirements parameter of a vkGetImageMemoryRequirements2 call, requiresDedicatedAllocation may be VK_TRUE under one of the following conditions:

• The pNext chain of VkImageCreateInfo for the call to vkCreateImage used to create the image being queried included a VkExternalMemoryImageCreateInfo structure, and any of the handle types specified in VkExternalMemoryImageCreateInfo::handleTypes requires dedicated allocation, as reported by vkGetPhysicalDeviceImageFormatProperties2 in VkExternalImageFormatProperties::externalMemoryProperties.externalMemoryFeatures, the requiresDedicatedAllocation field will be set to VK_TRUE.
In all other cases, `requiresDedicatedAllocation` must be set to `VK_FALSE` by the implementation whenever a `VkMemoryDedicatedRequirements` structure is included in the `pNext` chain of the `VkMemoryRequirements2` structure passed to a call to `vkGetImageMemoryRequirements2`.

If the `VkMemoryDedicatedRequirements` structure is included in the `pNext` chain of the `VkMemoryRequirements2` structure passed as the `pMemoryRequirements` parameter of a `vkGetImageMemoryRequirements2` call and `VK_IMAGE_CREATE_SPARSE_BINDING_BIT` was set in `VkImageCreateInfo::flags` when image was created then the implementation must set both `prefersDedicatedAllocation` and `requiresDedicatedAllocation` to `VK_FALSE`.

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_MEMORY_DEDICATED_REQUIREMENTS`

To attach memory to a buffer object, call:

```c
VkResult vkBindBufferMemory(
    VkDevice device,    // device is the logical device that owns the buffer and memory.
    VkBuffer buffer,    // buffer is the buffer to be attached to memory.
    VkDeviceMemory memory,    // memory is a VkDeviceMemory object describing the device memory to attach.
    VkDeviceSize memoryOffset);    // memoryOffset is the start offset of the region of memory which is to be bound to the buffer. The number of bytes returned in the VkMemoryRequirements::size member in memory, starting from memoryOffset bytes, will be bound to the specified buffer.
```

`vkBindBufferMemory` is equivalent to passing the same parameters through `VkBindBufferMemoryInfo` to `vkBindBufferMemory2`.
Valid Usage

- **buffer** must not already be backed by a memory object
- **buffer** must not have been created with any sparse memory binding flags
- **memoryOffset** must be less than the size of **memory**
- **memory** must have been allocated using one of the memory types allowed in the **memoryTypeBits** member of the **VkMemoryRequirements** structure returned from a call to **vkGetBufferMemoryRequirements** with **buffer**
- **memoryOffset** must be an integer multiple of the **alignment** member of the **VkMemoryRequirements** structure returned from a call to **vkGetBufferMemoryRequirements** with **buffer**
- The size member of the **VkMemoryRequirements** structure returned from a call to **vkGetBufferMemoryRequirements** with **buffer** must be less than or equal to the size of **memory** minus **memoryOffset**
- If **buffer** requires a dedicated allocation (as reported by **vkGetBufferMemoryRequirements2** in **VkMemoryDedicatedRequirements**::**requiresDedicatedAllocation** for **buffer**), **memory** must have been created with **VkMemoryDedicatedAllocateInfo**::**buffer** equal to **buffer**
- If the **VkMemoryAllocateInfo** provided when **memory** was allocated included a **VkMemoryDedicatedAllocateInfo** structure in its **pNext** chain, and **VkMemoryDedicatedAllocateInfo**::**buffer** was not **VK_NULL_HANDLE**, then **buffer** must equal **VkMemoryDedicatedAllocateInfo**::**buffer**, and **memoryOffset** must be zero
- If **buffer** was created with **VkDedicatedAllocationBufferCreateInfoNV**::**dedicatedAllocation** equal to **VK_TRUE**, **memory** must have been created with **VkDedicatedAllocationMemoryAllocateInfoNV**::**buffer** equal to a buffer handle created with identical creation parameters to **buffer** and **memoryOffset** must be zero
- If the value of **VkExportMemoryAllocateInfo**::**handleTypes** used to allocate **memory** is not 0, it must include at least one of the handles set in **VkExternalMemoryBufferCreateInfo**::**handleTypes** when **buffer** was created
- If **memory** was created by a memory import operation, that is not **VkImportAndroidHardwareBufferInfoANDROID** with a non-NULL **buffer** value, the external handle type of the imported memory must also have been set in **VkExternalMemoryBufferCreateInfo**::**handleTypes** when **buffer** was created
- If **memory** was created with the **VkImportAndroidHardwareBufferInfoANDROID** memory import operation with a non-NULL **buffer** value, **VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID** must also have been set in **VkExternalMemoryBufferCreateInfo**::**handleTypes** when **buffer** was created
- If the **VkPhysicalDeviceBufferDeviceAddressFeatures**::**bufferDeviceAddress** feature is enabled and **buffer** was created with the **VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT** bit set, **memory** must have been allocated with the **VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_BIT** bit set
**Valid Usage (Implicit)**

- **device** must be a valid `VkDevice` handle
- **buffer** must be a valid `VkBuffer` handle
- **memory** must be a valid `VkDeviceMemory` handle
- **buffer** must have been created, allocated, or retrieved from **device**
- **memory** must have been created, allocated, or retrieved from **device**

**Host Synchronization**

- Host access to **buffer** must be externally synchronized

**Return Codes**

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`
- `VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS_KHR`

To attach memory to buffer objects for one or more buffers at a time, call:

```
VkResult vkBindBufferMemory2KHR(
    VkDevice                                    device,
    uint32_t                                    bindInfoCount,
    const VkBindBufferMemoryInfo*               pBindInfos);
```

- **device** is the logical device that owns the buffers and memory.
- **bindInfoCount** is the number of elements in **pBindInfos**.
- **pBindInfos** is a pointer to an array of **bindInfoCount** `VkBindBufferMemoryInfo` structures describing buffers and memory to bind.

On some implementations, it **may** be more efficient to batch memory bindings into a single command.
Valid Usage (Implicit)

- device must be a valid VkDevice handle
- pBindInfos must be a valid pointer to an array of bindInfoCount valid VkBindBufferMemoryInfo structures
- bindInfoCount must be greater than 0

Return Codes

Success
- VK_SUCCESS

Failure
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS_KHR

VkBindBufferMemoryInfo contains members corresponding to the parameters of vkBindBufferMemory.

The VkBindBufferMemoryInfo structure is defined as:

```
typedef struct VkBindBufferMemoryInfo {
    VkStructureType    sType;
    const void*        pNext;
    VkBuffer           buffer;
    VkDeviceMemory     memory;
    VkDeviceSize       memoryOffset;
} VkBindBufferMemoryInfo;
```

or the equivalent

```
typedef VkBindBufferMemoryInfo VkBindBufferMemoryInfoKHR;
```

- sType is the type of this structure.
- pNext is NULL or a pointer to an extension-specific structure.
- buffer is the buffer to be attached to memory.
- memory is a VkDeviceMemory object describing the device memory to attach.
- memoryOffset is the start offset of the region of memory which is to be bound to the buffer. The number of bytes returned in the VkMemoryRequirements::size member in memory, starting from memoryOffset bytes, will be bound to the specified buffer.
Valid Usage

- **buffer must** not already be backed by a memory object
- **buffer must** not have been created with any sparse memory binding flags
- **memoryOffset must** be less than the size of **memory**
- **memory must** have been allocated using one of the memory types allowed in the `memoryTypeBits` member of the `VkMemoryRequirements` structure returned from a call to `vkGetBufferMemoryRequirements` with **buffer**
- **memoryOffset must** be an integer multiple of the `alignment` member of the `VkMemoryRequirements` structure returned from a call to `vkGetBufferMemoryRequirements` with **buffer**
- The **size** member of the `VkMemoryRequirements` structure returned from a call to `vkGetBufferMemoryRequirements` with **buffer must** be less than or equal to the size of **memory** minus **memoryOffset**
- If **buffer** requires a dedicated allocation (as reported by `vkGetBufferMemoryRequirements2` in `VkMemoryDedicatedRequirements::requiresDedicatedAllocation` for **buffer**), **memory must** have been created with `VkMemoryDedicatedAllocateInfo::buffer` equal to **buffer** and **memoryOffset must** be zero
- If the `VkMemoryAllocateInfo` provided when **memory** was allocated included a `VkMemoryDedicatedAllocateInfo` structure in its `pNext` chain, and `VkMemoryDedicatedAllocateInfo::buffer` was not `VK_NULL_HANDLE`, then **buffer must** equal `VkMemoryDedicatedAllocateInfo::buffer` and **memoryOffset must** be zero
- If **buffer** was created with `VkDedicatedAllocationBufferCreateInfoNV::dedicatedAllocation` equal to `VK_TRUE`, **memory must** have been created with `VkDedicatedAllocationMemoryAllocateInfoNV::buffer` equal to **buffer** and **memoryOffset must** be zero
- If the `pNext` chain includes a `VkBindBufferMemoryDeviceGroupInfo` structure, all instances of **memory** specified by `VkBindBufferMemoryDeviceGroupInfo::pDeviceIndices` **must** have been allocated
- If the value of `VkExportMemoryAllocateInfo::handleTypes` used to allocate **memory** is not `0`, it **must** include at least one of the handles set in `VkExternalMemoryBufferCreateInfo::handleTypes` when **buffer** was created
- If **memory** was created by a memory import operation, that is not `VkImportAndroidHardwareBufferInfoANDROID` with a non-`NULL` `buffer` value, the external handle type of the imported memory **must** also have been set in `VkExternalMemoryBufferCreateInfo::handleTypes` when **buffer** was created
- If **memory** was created with the `VkImportAndroidHardwareBufferInfoANDROID` memory import operation with a non-`NULL` `buffer` value, `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID` **must** also have been set in `VkExternalMemoryBufferCreateInfo::handleTypes` when **buffer** was created
- If the `VkPhysicalDeviceBufferDeviceAddressFeaturesKHR::bufferDeviceAddress` feature is
enabled and buffer was created with the VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT_KHR bit set, memory must have been allocated with the VK_MEMORY_ALLOCATE_DEVICE_ADDRESS_BIT_KHR bit set.

### Valid Usage (Implicit)

- **sType** must be VK_STRUCTURE_TYPE_BIND_BUFFER_MEMORY_INFO
- **pNext** must be NULL or a pointer to a valid instance of VkBindBufferMemoryDeviceGroupInfo
- The sType value of each struct in the pNext chain must be unique
- buffer must be a valid VkBuffer handle
- memory must be a valid VkDeviceMemory handle
- Both of buffer, and memory must have been created, allocated, or retrieved from the same VkDevice

```c
typedef struct VkBindBufferMemoryDeviceGroupInfo {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           deviceIndexCount;
    const uint32_t*    pDeviceIndices;
} VkBindBufferMemoryDeviceGroupInfo;
```

or the equivalent

```c
typedef VkBindBufferMemoryDeviceGroupInfo VkBindBufferMemoryDeviceGroupInfoKHR;
```

If the pNext list of VkBindBufferMemoryInfo includes a VkBindBufferMemoryDeviceGroupInfo structure, then that structure determines how memory is bound to buffers across multiple devices in a device group.

The VkBindBufferMemoryDeviceGroupInfo structure is defined as:

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **deviceIndexCount** is the number of elements in pDeviceIndices.
- **pDeviceIndices** is a pointer to an array of device indices.

If deviceIndexCount is greater than zero, then on device index i the buffer is attached to the instance of memory on the physical device with device index pDeviceIndices[i].

If deviceIndexCount is zero and memory comes from a memory heap with the VK_MEMORY_HEAP_MULTI_INSTANCE_BIT bit set, then it is as if pDeviceIndices contains consecutive
indices from zero to the number of physical devices in the logical device, minus one. In other words, by default each physical device attaches to its own instance of memory.

If `deviceIndexCount` is zero and `memory` comes from a memory heap without the `VK_MEMORY_HEAP_MULTI_INSTANCE_BIT` bit set, then it is as if `pDeviceIndices` contains an array of zeros. In other words, by default each physical device attaches to instance zero.

### Valid Usage

- `deviceIndexCount` **must** either be zero or equal to the number of physical devices in the logical device.
- All elements of `pDeviceIndices` **must** be valid device indices.

### Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_BIND_BUFFER_MEMORY_DEVICE_GROUP_INFO`.
- If `deviceIndexCount` is not 0, `pDeviceIndices` **must** be a valid pointer to an array of `deviceIndexCount` uint32_t values.

To attach memory to a `VkImage` object created without the `VK_IMAGE_CREATE_DISJOINT_BIT` set, call:

```cpp
VkResult vkBindImageMemory(
    VkDevice device,
    VkImage image,
    VkDeviceMemory memory,
    VkDeviceSize memoryOffset);
```

- `device` is the logical device that owns the image and memory.
- `image` is the image.
- `memory` is the `VkDeviceMemory` object describing the device memory to attach.
- `memoryOffset` is the start offset of the region of `memory` which is to be bound to the image. The number of bytes returned in the `VkMemoryRequirements::size` member in `memory`, starting from `memoryOffset` bytes, will be bound to the specified image.

`vkBindImageMemory` is equivalent to passing the same parameters through `VkBindImageMemoryInfo` to `vkBindImageMemory2`.
Valid Usage

- **image** must not have been created with the `VK_IMAGE_CREATE_DISJOINT_BIT` set
- **image** must not already be backed by a memory object
- **image** must not have been created with any sparse memory binding flags
- **memoryOffset** must be less than the size of **memory**
- **memory** must have been allocated using one of the memory types allowed in the `memoryTypeBits` member of the `VkMemoryRequirements` structure returned from a call to `vkGetImageMemoryRequirements` with **image**
- **memoryOffset** must be an integer multiple of the `alignment` member of the `VkMemoryRequirements` structure returned from a call to `vkGetImageMemoryRequirements` with **image**
- The difference of the size of **memory** and **memoryOffset** must be greater than or equal to the `size` member of the `VkMemoryRequirements` structure returned from a call to `vkGetImageMemoryRequirements` with the same **image**
- If **image** requires a dedicated allocation (as reported by `vkGetImageMemoryRequirements2` in `VkMemoryDedicatedRequirements::requiresDedicatedAllocation` for **image**), **memory** must have been created with `VkMemoryDedicatedAllocateInfo::image` equal to **image**
- If the dedicated allocation image aliasing feature is not enabled, and the `VkMemoryAllocateInfo` provided when **memory** was allocated included a `VkMemoryDedicatedAllocateInfo` structure in its `pNext` chain, and `VkMemoryDedicatedAllocateInfo::image` was not `VK_NULL_HANDLE`, then **image** must equal `VkMemoryDedicatedAllocateInfo::image` and **memoryOffset** must be zero
- If the dedicated allocation image aliasing feature is enabled, and the `VkMemoryAllocateInfo` provided when **memory** was allocated included a `VkMemoryDedicatedAllocateInfo` structure in its `pNext` chain, and `VkMemoryDedicatedAllocateInfo::image` was not `VK_NULL_HANDLE`, then **memoryOffset** must be zero, and **image** must be either equal to `VkMemoryDedicatedAllocateInfo::image` or an image that was created using the same parameters in `VkImageCreateInfo`, with the exception that `extent` and `arrayLayers` may differ subject to the following restrictions: every dimension in the `extent` parameter of the image being bound must be equal to or smaller than the original image for which the allocation was created; and the `arrayLayers` parameter of the image being bound must be equal to or smaller than the original image for which the allocation was created
- If **image** was created with `VkDedicatedAllocationImageCreateInfoNV::dedicatedAllocation` equal to `VK_TRUE`, **memory** must have been created with `VkDedicatedAllocationMemoryAllocateInfoNV::image` equal to an image handle created with identical creation parameters to **image** and **memoryOffset** must be zero
- If the value of `VkExportMemoryAllocateInfo::handleTypes` used to allocate **memory** is not `0`, it must include at least one of the handles set in `VkExternalMemoryImageCreateInfo` `::handleTypes` when **image** was created
- If **memory** was created by a memory import operation, that is not `VkImportAndroidHardwareBufferInfoANDROID` with a non-NULL buffer value, the
external handle type of the imported memory must also have been set in VkExternalMemoryImageCreateInfo::handleTypes when image was created

- If memory was created with the VkImportAndroidHardwareBufferInfoANDROID memory import operation with a non-NULL buffer value, VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID must also have been set in VkExternalMemoryImageCreateInfo::handleTypes when image was created

Valid Usage (Implicit)

- device must be a valid VkDevice handle
- image must be a valid VkImage handle
- memory must be a valid VkDeviceMemory handle
- image must have been created, allocated, or retrieved from device
- memory must have been created, allocated, or retrieved from device

Host Synchronization

- Host access to image must be externally synchronized

Return Codes

Success
- VK_SUCCESS

Failure
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

To attach memory to image objects for one or more images at a time, call:

```c
VkResult vkBindImageMemory2KHR(
    VkDevice                                    device,
    uint32_t                                    bindInfoCount,
    const VkBindImageMemoryInfo*                pBindInfos);
```

- device is the logical device that owns the images and memory.
- bindInfoCount is the number of elements in pBindInfos.
- pBindInfos is a pointer to an array of VkBindImageMemoryInfo structures, describing images and memory to bind.
On some implementations, it may be more efficient to batch memory bindings into a single command.

### Valid Usage

- If any `VkBindImageMemoryInfo::image` was created with `VK_IMAGE_CREATE_DISJOINT_BIT` then all planes of `VkBindImageMemoryInfo::image` must be bound individually in separate `pBindInfos`
- `pBindInfos` must not refer to the same image subresource more than once

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `pBindInfos` must be a valid pointer to an array of `bindInfoCount` valid `VkBindImageMemoryInfo` structures
- `bindInfoCount` must be greater than 0

### Return Codes

**Success**
- `VK_SUCCESS`

**Failure**
- `VK_ERROR_OUT_OF_HOST_MEMORY`
- `VK_ERROR_OUT_OF_DEVICE_MEMORY`

`VkBindImageMemoryInfo` contains members corresponding to the parameters of `vkBindImageMemory`.

The `VkBindImageMemoryInfo` structure is defined as:

```c
typedef struct VkBindImageMemoryInfo {
    VkStructureType sType;
    const void* pNext;
    VkImage image;
    VkDeviceMemory memory;
    VkDeviceSize memoryOffset;
} VkBindImageMemoryInfo;
```

or the equivalent

```c
typedef VkBindImageMemoryInfo VkBindImageMemoryInfoKHR;
```
• **sType** is the type of this structure.

• **pNext** is **NULL** or a pointer to an extension-specific structure.

• **image** is the image to be attached to memory.

• **memory** is a **VkDeviceMemory** object describing the device memory to attach.

• **memoryOffset** is the start offset of the region of **memory** which is to be bound to the image. The number of bytes returned in the **VkMemoryRequirements::size** member in **memory**, starting from **memoryOffset** bytes, will be bound to the specified image.
Valid Usage

- **image** must not already be backed by a memory object
- **image** must not have been created with any sparse memory binding flags
- **memoryOffset** must be less than the size of **memory**

If the **pNext** chain does not include a `VkBindImagePlaneMemoryInfo` structure, **memory** must have been allocated using one of the memory types allowed in the **memoryTypeBits** member of the **VkMemoryRequirements** structure returned from a call to `vkGetImageMemoryRequirements2` with **image**

If the **pNext** chain does not include a `VkBindImagePlaneMemoryInfo` structure, **memoryOffset** must be an integer multiple of the **alignment** member of the **VkMemoryRequirements** structure returned from a call to `vkGetImageMemoryRequirements2` with **image**

If the **pNext** chain does not include a `VkBindImagePlaneMemoryInfo` structure, the difference of the size of **memory** and **memoryOffset** must be greater than or equal to the size member of the **VkMemoryRequirements** structure returned from a call to `vkGetImageMemoryRequirements2` with the same **image**

If the **pNext** chain includes a `VkBindImagePlaneMemoryInfo` structure, **image** must have been created with the `VK_IMAGE_CREATE_DISJOINT_BIT` bit set

If the **pNext** chain includes a `VkBindImagePlaneMemoryInfo` structure, **memory** must have been allocated using one of the memory types allowed in the **memoryTypeBits** member of the **VkMemoryRequirements** structure returned from a call to `vkGetImageMemoryRequirements2` with **image** and where `VkBindImagePlaneMemoryInfo::planeAspect` corresponds to the `VkImagePlaneMemoryRequirementsInfo::planeAspect` in the `VkImageMemoryRequirementsInfo2` structure's **pNext** chain

If the **pNext** chain includes a `VkBindImagePlaneMemoryInfo` structure, **memoryOffset** must be an integer multiple of the **alignment** member of the **VkMemoryRequirements** structure returned from a call to `vkGetImageMemoryRequirements2` with **image** and where `VkBindImagePlaneMemoryInfo::planeAspect` corresponds to the `VkImagePlaneMemoryRequirementsInfo::planeAspect` in the `VkImageMemoryRequirementsInfo2` structure's **pNext** chain

If the **pNext** chain includes a `VkBindImagePlaneMemoryInfo` structure, the difference of the size of **memory** and **memoryOffset** must be greater than or equal to the size member of the **VkMemoryRequirements** structure returned from a call to `vkGetImageMemoryRequirements2` with the same **image** and where `VkBindImagePlaneMemoryInfo::planeAspect` corresponds to the `VkImagePlaneMemoryRequirementsInfo::planeAspect` in the `VkImageMemoryRequirementsInfo2` structure's **pNext** chain

If **image** requires a dedicated allocation (as reported by `vkGetImageMemoryRequirements2` in `VkMemoryDedicatedRequirements::requiresDedicatedAllocation` for **image**), **memory** must have been created with `VkMemoryDedicatedAllocateInfo::image` equal to **image** and
memoryOffset must be zero

- If the dedicated allocation image aliasing feature is not enabled, and the VkMemoryAllocateInfo provided when memory was allocated included a VkMemoryDedicatedAllocateInfo structure in its pNext chain, and VkMemoryDedicatedAllocateInfo::image was not VK_NULL_HANDLE, then image must equal VkMemoryDedicatedAllocateInfo::image and memoryOffset must be zero.

- If the dedicated allocation image aliasing feature is enabled, and the VkMemoryAllocateInfo provided when memory was allocated included a VkMemoryDedicatedAllocateInfo structure in its pNext chain, and VkMemoryDedicatedAllocateInfo::image was not VK_NULL_HANDLE, then memoryOffset must be zero, and image must be either equal to VkMemoryDedicatedAllocateInfo::image or an image that was created using the same parameters in VkImageCreateInfo, with the exception that extent and arrayLayers may differ subject to the following restrictions: every dimension in the extent parameter of the image being bound must be equal to or smaller than the original image for which the allocation was created; and the arrayLayers parameter of the image being bound must be equal to or smaller than the original image for which the allocation was created.

- If image was created with VkDedicatedAllocationImageCreateInfoNV::dedicatedAllocation equal to VK_TRUE, memory must have been created with VkDedicatedAllocationMemoryAllocateInfoNV::image equal to image and memoryOffset must be zero.

- If the pNext chain includes a VkBindImageMemoryDeviceGroupInfo structure, all instances of memory specified by VkBindImageMemoryDeviceGroupInfo::pDeviceIndices must have been allocated.

- If the pNext chain includes a VkBindImageMemoryDeviceGroupInfo structure, and VkBindImageMemoryDeviceGroupInfo::splitInstanceBindRegionCount is not zero, then image must have been created with the VK_IMAGE_CREATE_SPLIT_INSTANCE_BIND_REGIONS_BIT bit set.

- If the pNext chain includes a VkBindImageMemoryDeviceGroupInfo structure, all elements of VkBindImageMemoryDeviceGroupInfo::pSplitInstanceBindRegions must be valid rectangles contained within the dimensions of image.

- If the pNext chain includes a VkBindImageMemoryDeviceGroupInfo structure, the union of the areas of all elements of VkBindImageMemoryDeviceGroupInfo::pSplitInstanceBindRegions that correspond to the same instance of image must cover the entire image.

- If image was created with a valid swapchain handle in VkImageSwapchainCreateInfoKHR::swapchain, then the pNext chain must include a VkBindImageMemorySwapchainInfoKHR structure containing the same swapchain handle.

- If the pNext chain includes a VkBindImageMemorySwapchainInfoKHR structure, memory must be VK_NULL_HANDLE.

- If the pNext chain does not include a VkBindImageMemorySwapchainInfoKHR structure, memory must be a valid VkDeviceMemory handle.

- If the value of VkExportMemoryAllocateInfo::handleTypes used to allocate memory is not 0, it...
**must** include at least one of the handles set in `VkExternalMemoryImageCreateInfo::handleTypes` when `image` was created

- If `memory` was created by a memory import operation, that is not `VkImportAndroidHardwareBufferInfoANDROID` with a non-NULL `buffer` value, the external handle type of the imported memory **must** also have been set in `VkExternalMemoryImageCreateInfo::handleTypes` when `image` was created.

- If `memory` was created with the `VkImportAndroidHardwareBufferInfoANDROID` memory import operation with a non-NULL `buffer` value, `VK_EXTERNAL_MEMORY_HANDLE_TYPE_ANDROID_HARDWARE_BUFFER_BIT_ANDROID` **must** also have been set in `VkExternalMemoryImageCreateInfo::handleTypes` when `image` was created.

---

**Valid Usage (Implicit)**

- `sType` **must** be `VK_STRUCTURE_TYPE_BIND_IMAGE_MEMORY_INFO`

- Each `pNext` member of any structure (including this one) in the `pNext` chain **must** be either `NULL` or a pointer to a valid instance of `VkBindImageMemoryDeviceGroupInfo`, `VkBindImageMemorySwapchainInfoKHR`, or `VkBindImagePlaneMemoryInfo`.

- The `sType` value of each struct in the `pNext` chain **must** be unique.

- `image` **must** be a valid `VkImage` handle.

- Both of `image`, and `memory` that are valid handles of non-ignored parameters **must** have been created, allocated, or retrieved from the same `VkDevice`.

---

```c
typedef struct VkBindImageMemoryDeviceGroupInfo {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           deviceIndexCount;
    const uint32_t*    pDeviceIndices;
    uint32_t           splitInstanceBindRegionCount;
    const VkRect2D*    pSplitInstanceBindRegions;
} VkBindImageMemoryDeviceGroupInfo;
```

or the equivalent

```c
typedef VkBindImageMemoryDeviceGroupInfo VkBindImageMemoryDeviceGroupInfoKHR;
```

If the `pNext` list of `VkBindImageMemoryInfo` includes a `VkBindImageMemoryDeviceGroupInfo` structure, then that structure determines how memory is bound to images across multiple devices in a device group.

The `VkBindImageMemoryDeviceGroupInfo` structure is defined as:

- `sType` is the type of this structure.
• **pNext** is NULL or a pointer to an extension-specific structure.
• **deviceIndexCount** is the number of elements in **pDeviceIndices**.
• **pDeviceIndices** is a pointer to an array of device indices.
• **splitInstanceBindRegionCount** is the number of elements in **pSplitInstanceBindRegions**.
• **pSplitInstanceBindRegions** is a pointer to an array of **VkRect2D** structures describing which regions of the image are attached to each instance of memory.

If **deviceIndexCount** is greater than zero, then on device index **i** image is attached to the instance of the memory on the physical device with device index **pDeviceIndices[i]**.

Let **N** be the number of physical devices in the logical device. If **splitInstanceBindRegionCount** is greater than zero, then **pSplitInstanceBindRegions** is an array of **N^2** rectangles, where the image region specified by the rectangle at element **i*N+j** in resource instance **i** is bound to the memory instance **j**. The blocks of the memory that are bound to each sparse image block region use an offset in memory, relative to **memoryOffset**, computed as if the whole image were being bound to a contiguous range of memory. In other words, horizontally adjacent image blocks use consecutive blocks of memory, vertically adjacent image blocks are separated by the number of bytes per block multiplied by the width in blocks of image, and the block at (0,0) corresponds to memory starting at **memoryOffset**.

If **splitInstanceBindRegionCount** and **deviceIndexCount** are zero and the memory comes from a memory heap with the **VK_MEMORY_HEAP_MULTI_INSTANCE_BIT** bit set, then it is as if **pDeviceIndices** contains consecutive indices from zero to the number of physical devices in the logical device, minus one. In other words, by default each physical device attaches to its own instance of the memory.

If **splitInstanceBindRegionCount** and **deviceIndexCount** are zero and the memory comes from a memory heap without the **VK_MEMORY_HEAP_MULTI_INSTANCE_BIT** bit set, then it is as if **pDeviceIndices** contains an array of zeros. In other words, by default each physical device attaches to instance zero.
Valid Usage

- At least one of `deviceIndexCount` and `splitInstanceBindRegionCount` must be zero
- `deviceIndexCount` must either be zero or equal to the number of physical devices in the logical device
- All elements of `pDeviceIndices` must be valid device indices
- `splitInstanceBindRegionCount` must either be zero or equal to the number of physical devices in the logical device squared
- Elements of `pSplitInstanceBindRegions` that correspond to the same instance of an image must not overlap
- The `offset.x` member of any element of `pSplitInstanceBindRegions` must be a multiple of the sparse image block width (VKSparseImageFormatProperties::imageGranularity.width) of all non-metadata aspects of the image
- The `offset.y` member of any element of `pSplitInstanceBindRegions` must be a multiple of the sparse image block height (VKSparseImageFormatProperties::imageGranularity.height) of all non-metadata aspects of the image
- The `extent.width` member of any element of `pSplitInstanceBindRegions` must either be a multiple of the sparse image block width of all non-metadata aspects of the image, or else `extent.width + offset.x` must equal the width of the image subresource
- The `extent.height` member of any element of `pSplitInstanceBindRegions` must either be a multiple of the sparse image block height of all non-metadata aspects of the image, or else `extent.height + offset.y` must equal the width of the image subresource

Valid Usage (Implicit)

- `sType` must be VK_STRUCTURE_TYPE_BIND_IMAGE_MEMORY_DEVICE_GROUP_INFO
- If `deviceIndexCount` is not 0, `pDeviceIndices` must be a valid pointer to an array of `deviceIndexCount` uint32_t values
- If `splitInstanceBindRegionCount` is not 0, `pSplitInstanceBindRegions` must be a valid pointer to an array of `splitInstanceBindRegionCount` VkRect2D structures

If the `pNext` chain of VkBindImageMemoryInfo includes a VkBindImageMemorySwapchainInfoKHR structure, then that structure includes a swapchain handle and image index indicating that the image will be bound to memory from that swapchain.

The VkBindImageMemorySwapchainInfoKHR structure is defined as:
typedef struct VkBindImageMemorySwapchainInfoKHR {
    VkStructureType    sType;
    const void*        pNext;
    VkSwapchainKHR     swapchain;
    uint32_t           imageIndex;
} VkBindImageMemorySwapchainInfoKHR;

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **swapchain** is **VK_NULL_HANDLE** or a swapchain handle.
- **imageIndex** is an image index within **swapchain**.

If **swapchain** is not **NULL**, the **swapchain** and **imageIndex** are used to determine the memory that the image is bound to, instead of **memory** and **memoryOffset**.

Memory can be bound to a swapchain and use the **pDeviceIndices** or **pSplitInstanceBindRegions** members of **VkBindImageMemoryDeviceGroupInfo**.

### Valid Usage

- **imageIndex** **must** be less than the number of images in **swapchain**

### Valid Usage (Implicit)

- **sType** **must** be **VK_STRUCTURE_TYPE_BIND_IMAGE_MEMORY_SWAPCHAIN_INFO_KHR**
- **swapchain** **must** be a valid **VkSwapchainKHR** handle

### Host Synchronization

- Host access to **swapchain** **must** be externally synchronized

In order to bind **planes** of a **disjoint image**, add a **VkBindImagePlaneMemoryInfo** structure to the **pNext** chain of **VkBindImageMemoryInfo**.

The **VkBindImagePlaneMemoryInfo** structure is defined as:

typedef struct VkBindImagePlaneMemoryInfo {
    VkStructureType          sType;
    const void*              pNext;
    VkImageAspectFlagBits    planeAspect;
} VkBindImagePlaneMemoryInfo;
or the equivalent

```c
typedef VkBindImagePlaneMemoryInfo VkBindImagePlaneMemoryInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `planeAspect` is the aspect of the disjoint image plane to bind.

### Valid Usage

- If the image's `tiling` is `VK_IMAGE_TILING_LINEAR` or `VK_IMAGE_TILING_OPTIMAL`, then `planeAspect` must be a single valid `format plane` for the image (that is, for a two-plane image `planeAspect` must be `VK_IMAGE_ASPECT_PLANE_0_BIT` or `VK_IMAGE_ASPECT_PLANE_1_BIT`, and for a three-plane image `planeAspect` must be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT` or `VK_IMAGE_ASPECT_PLANE_2_BIT`)

- If the image's `tiling` is `VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT`, then `planeAspect` must be a single valid `memory plane` for the image (that is, `aspectMask` must specify a plane index that is less than the `VkDrmFormatModifierPropertiesEXT::drmFormatModifierPlaneCount` associated with the image's `format` and `VkImageDrmFormatModifierPropertiesEXT::drmFormatModifier`)

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_BIND_IMAGE_PLANE_MEMORY_INFO`
- `planeAspect` must be a valid `VkImageAspectFlagBits` value

---

### Buffer-Image Granularity

There is an implementation-dependent limit, `bufferImageGranularity`, which specifies a page-like granularity at which linear and non-linear resources must be placed in adjacent memory locations to avoid aliasing. Two resources which do not satisfy this granularity requirement are said to alias. `bufferImageGranularity` is specified in bytes, and `must` be a power of two. Implementations which do not impose a granularity restriction may report a `bufferImageGranularity` value of one.

**Note**

Despite its name, `bufferImageGranularity` is really a granularity between “linear” and “non-linear” resources.

Given resourceA at the lower memory offset and resourceB at the higher memory offset in the same `VkDeviceMemory` object, where one resource is linear and the other is non-linear (as defined in the Glossary), and the following:
The following property must hold:

\[
\text{resourceA.endPage} < \text{resourceB.startPage}
\]

That is, the end of the first resource (A) and the beginning of the second resource (B) must be on separate “pages” of size bufferImageGranularity. bufferImageGranularity may be different than the physical page size of the memory heap. This restriction is only needed when a linear resource and a non-linear resource are adjacent in memory and will be used simultaneously. The memory ranges of adjacent resources can be closer than bufferImageGranularity, provided they meet the alignment requirement for the objects in question.

Sparse block size in bytes and sparse image and buffer memory alignments must all be multiples of the bufferImageGranularity. Therefore, memory bound to sparse resources naturally satisfies the bufferImageGranularity.

11.7. Resource Sharing Mode

Buffer and image objects are created with a sharing mode controlling how they can be accessed from queues. The supported sharing modes are:

```c
typedef enum VkSharingMode {
    VK_SHARING_MODE_EXCLUSIVE = 0,
    VK_SHARING_MODE_CONCURRENT = 1,
} VkSharingMode;
```

- **VK_SHARING_MODE_EXCLUSIVE** specifies that access to any range or image subresource of the object will be exclusive to a single queue family at a time.

- **VK_SHARING_MODE_CONCURRENT** specifies that concurrent access to any range or image subresource of the object from multiple queue families is supported.

Note

VK_SHARING_MODE_CONCURRENT may result in lower performance access to the buffer or image than VK_SHARING_MODE_EXCLUSIVE.

Ranges of buffers and image subresources of image objects created using VK_SHARING_MODE_EXCLUSIVE must only be accessed by queues in the queue family that has ownership of the resource. Upon creation, such resources are not owned by any queue family; ownership is implicitly acquired upon first use within a queue. Once a resource using VK_SHARING_MODE_EXCLUSIVE is owned by some queue family, the application must perform a queue family ownership transfer to make the memory...
contents of a range or image subresource accessible to a different queue family.

Note
Images still require a layout transition from VK_IMAGE_LAYOUT_UNDEFINED or VK_IMAGE_LAYOUT_PREINITIALIZED before being used on the first queue.

A queue family can take ownership of an image subresource or buffer range of a resource created with VK_SHARING_MODE_EXCLUSIVE, without an ownership transfer, in the same way as for a resource that was just created; however, taking ownership in this way has the effect that the contents of the image subresource or buffer range are undefined.

Ranges of buffers and image subresources of image objects created using VK_SHARING_MODE_CONCURRENT must only be accessed by queues from the queue families specified through the queueFamilyIndexCount and pQueueFamilyIndices members of the corresponding create info structures.

11.7.1. External Resource Sharing

Resources should only be accessed in the Vulkan instance that has exclusive ownership of their underlying memory. Only one Vulkan instance has exclusive ownership of a resource's underlying memory at a given time, regardless of whether the resource was created using VK_SHARING_MODE_EXCLUSIVE or VK_SHARING_MODE_CONCURRENT. Applications can transfer ownership of a resource's underlying memory only if the memory has been imported from or exported to another instance or external API using external memory handles. The semantics for transferring ownership outside of the instance are similar to those used for transferring ownership of VK_SHARING_MODE_EXCLUSIVE resources between queues, and is also accomplished using VkBufferMemoryBarrier or VkImageMemoryBarrier operations. Applications must

1. Release exclusive ownership from the source instance or API.
2. Ensure the release operation has completed using semaphores or fences.
3. Acquire exclusive ownership in the destination instance or API.

Unlike queue ownership transfers, the destination instance or API is not specified explicitly when releasing ownership, nor is the source instance or API specified when acquiring ownership. Instead, the image or memory barrier's dstQueueFamilyIndex or srcQueueFamilyIndex parameters are set to the reserved queue family index VK_QUEUE_FAMILY_EXTERNAL or VK_QUEUE_FAMILY_FOREIGN_EXT to represent the external destination or source respectively.

Binding a resource to a memory object shared between multiple Vulkan instances or other APIs does not change the ownership of the underlying memory. The first entity to access the resource implicitly acquires ownership. Accessing a resource backed by memory that is owned by a particular instance or API has the same semantics as accessing a VK_SHARING_MODE_EXCLUSIVE resource, with one exception: Implementations must ensure layout transitions performed on one member of a set of identical subresources of identical images that alias the same range of an underlying memory object affect the layout of all the subresources in the set.

As a corollary, writes to any image subresources in such a set must not make the contents of memory used by other subresources in the set undefined. An application can define the content of
a subresource of one image by performing device writes to an identical subresource of another image provided both images are bound to the same region of external memory. Applications may also add resources to such a set after the content of the existing set members has been defined without making the content undefined by creating a new image with the initial layout VK_IMAGE_LAYOUT_UNDEFINED and binding it to the same region of external memory as the existing images.

Note
Because layout transitions apply to all identical images aliasing the same region of external memory, the actual layout of the memory backing a new image as well as an existing image with defined content will not be undefined. Such an image is not usable until it acquires ownership of its memory from the existing owner. Therefore, the layout specified as part of this transition will be the true initial layout of the image. The undefined layout specified when creating it is a placeholder to simplify valid usage requirements.

11.8. Memory Aliasing

A range of a VkDeviceMemory allocation is aliased if it is bound to multiple resources simultaneously, as described below, via vkBindImageMemory, vkBindBufferMemory, vkBindAccelerationStructureMemoryKHR, vkBindAccelerationStructureMemoryNV, via sparse memory bindings, or by binding the memory to resources in multiple Vulkan instances or external APIs using external memory handle export and import mechanisms.

Consider two resources, resource\(_A\) and resource\(_B\), bound respectively to memory range\(_A\) and range\(_B\). Let paddedRange\(_A\) and paddedRange\(_B\) be, respectively, range\(_A\) and range\(_B\) aligned to bufferImageGranularity. If the resources are both linear or both non-linear (as defined in the Glossary), then the resources alias the memory in the intersection of range\(_A\) and range\(_B\). If one resource is linear and the other is non-linear, then the resources alias the memory in the intersection of paddedRange\(_A\) and paddedRange\(_B\).

Applications can alias memory, but use of multiple aliases is subject to several constraints.

Note
Memory aliasing can be useful to reduce the total device memory footprint of an application, if some large resources are used for disjoint periods of time.

When a non-linear, non-VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT image is bound to an aliased range, all image subresources of the image overlap the range. When a linear image is bound to an aliased range, the image subresources that (according to the image’s advertised layout) include bytes from the aliased range overlap the range. When a VK_IMAGE_CREATE_SPARSE_RESIDENCY_BIT image has sparse image blocks bound to an aliased range, only image subresources including those sparse image blocks overlap the range, and when the memory bound to the image’s mip tail overlaps an aliased range all image subresources in the mip tail overlap the range.

Buffers, and linear image subresources in either the VK_IMAGE_LAYOUT_PREINITIALIZED or VK_IMAGE_LAYOUT_GENERAL layouts, are host-accessible subresources. That is, the host has a well-
defined addressing scheme to interpret the contents, and thus the layout of the data in memory can be consistently interpreted across aliases if each of those aliases is a host-accessible subresource. Non-linear images, and linear image subresources in other layouts, are not host-accessible.

If two aliases are both host-accessible, then they interpret the contents of the memory in consistent ways, and data written to one alias can be read by the other alias.

If two aliases are both images that were created with identical creation parameters, both were created with the `VK_IMAGE_CREATE_ALIAS_BIT` flag set, and both are bound identically to memory except for `VkBindImageMemoryDeviceGroupInfo::pDeviceIndices` and `VkBindImageMemoryDeviceGroupInfo::pSplitInstanceBindRegions`, then they interpret the contents of the memory in consistent ways, and data written to one alias can be read by the other alias.

Additionally, if an invididual plane of a multi-planar image and a single-plane image alias the same memory, then they also interpret the contents of the memory in consistent ways under the same conditions, but with the following modifications:

- Both must have been created with the `VK_IMAGE_CREATE_DISJOINT_BIT` flag.
- The single-plane image must have a `VkFormat` that is equivalent to that of the multi-planar image’s individual plane.
- The single-plane image and the individual plane of the multi-planar image must be bound identically to memory except for `VkBindImageMemoryDeviceGroupInfo::pDeviceIndices` and `VkBindImageMemoryDeviceGroupInfo::pSplitInstanceBindRegions`.
- The width and height of the single-plane image are derived from the multi-planar image’s dimensions in the manner listed for plane compatibility for the aliased plane.
- If either image’s tiling is `VK_IMAGE_TILING_OVRM_FORMAT_MODIFIER_EXT`, then both images must be linear.
- All other creation parameters must be identical

Aliases created by binding the same memory to resources in multiple Vulkan instances or external APIs using external memory handle export and import mechanisms interpret the contents of the memory in consistent ways, and data written to one alias can be read by the other alias.

Otherwise, the aliases interpret the contents of the memory differently, and writes via one alias make the contents of memory partially or completely undefined to the other alias. If the first alias is a host-accessible subresource, then the bytes affected are those written by the memory operations according to its addressing scheme. If the first alias is not host-accessible, then the bytes affected are those overlapped by the image subresources that were written. If the second alias is a host-accessible subresource, the affected bytes become undefined. If the second alias is a not host-accessible, all sparse image blocks (for sparse partially-resident images) or all image subresources (for non-sparse image and fully resident sparse images) that overlap the affected bytes become undefined.

If any image subresources are made undefined due to writes to an alias, then each of those image subresources must have its layout transitioned from `VK_IMAGE_LAYOUT_UNDEFINED` to a valid layout before it is used, or from `VK_IMAGE_LAYOUT_PREINITIALIZED` if the memory has been written by the host. If any sparse blocks of a sparse image have been made undefined, then only the image...
subresources containing them must be transitioned.

Use of an overlapping range by two aliases must be separated by a memory dependency using the appropriate access types if at least one of those uses performs writes, whether the aliases interpret memory consistently or not. If buffer or image memory barriers are used, the scope of the barrier must contain the entire range and/or set of image subresources that overlap.

If two aliasing image views are used in the same framebuffer, then the render pass must declare the attachments using the `VK_ATTACHMENT_DESCRIPTION_MAY_ALIAS_BIT`, and follow the other rules listed in that section.

Note

Memory recycled via an application suballocator (i.e. without freeing and reallocating the memory objects) is not substantially different from memory aliasing. However, a suballocator usually waits on a fence before recycling a region of memory, and signaling a fence involves sufficient implicit dependencies to satisfy all the above requirements.

11.9. Acceleration Structures

Acceleration structures are an opaque structure that is built by the implementation to more efficiently perform spatial queries on the provided geometric data. For this extension, an acceleration structure is either a top-level acceleration structure containing a set of bottom-level acceleration structures or a bottom-level acceleration structure containing either a set of axis-aligned bounding boxes for custom geometry or a set of triangles.

Each instance in the top-level acceleration structure contains a reference to a bottom-level acceleration structure as well as an instance transform plus information required to index into the shader bindings. The top-level acceleration structure is what is bound to the acceleration descriptor to trace inside the shader in the ray tracing pipeline.

Acceleration structures are represented by `VkAccelerationStructureKHR` handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkAccelerationStructureKHR)
```

or the equivalent

```c
typedef VkAccelerationStructureKHR VkAccelerationStructureNV;
```

To create acceleration structures, call:
VkResult vkCreateAccelerationStructureNV(
    VkDevice device,
    const VkAccelerationStructureCreateInfoNV* pCreateInfo,
    const VkAllocationCallbacks* pAllocator,
    VkAccelerationStructureNV* pAccelerationStructure);

- `device` is the logical device that creates the buffer object.
- `pCreateInfo` is a pointer to a `VkAccelerationStructureCreateInfoNV` structure containing parameters affecting creation of the acceleration structure.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
- `pAccelerationStructure` is a pointer to a `VkAccelerationStructureNV` handle in which the resulting acceleration structure object is returned.

Similar to other objects in Vulkan, the acceleration structure creation merely creates an object with a specific “shape” as specified by the information in `VkAccelerationStructureInfoNV` and `compactedSize` in `pCreateInfo`. Populating the data in the object after allocating and binding memory is done with `vkCmdBuildAccelerationStructureNV` and `vkCmdCopyAccelerationStructureNV`.

Acceleration structure creation uses the count and type information from the geometries, but does not use the data references in the structures.

**Valid Usage (Implicit)**

- `device` must be a valid `VkDevice` handle
- `pCreateInfo` must be a valid pointer to a valid `VkAccelerationStructureCreateInfoNV` structure
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- `pAccelerationStructure` must be a valid pointer to a `VkAccelerationStructureNV` handle

**Return Codes**

**Success**
- `VK_SUCCESS`

**Failure**
- `VK_ERROR_OUT_OF_HOST_MEMORY`

The `VkAccelerationStructureCreateInfoNV` structure is defined as:
typedef struct VkAccelerationStructureCreateInfoNV {
    VkStructureType                  sType;
    const void*                      pNext;
    VkDeviceSize                     compactedSize;
    VkAccelerationStructureInfoNV    info;
} VkAccelerationStructureCreateInfoNV;

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `compactedSize` is the size from the result of `vkCmdWriteAccelerationStructuresPropertiesNV` if this acceleration structure is going to be the target of a compacting copy.
- `info` is the `VkAccelerationStructureInfoNV` structure specifying further parameters of the created acceleration structure.

**Valid Usage**

- If `compactedSize` is not 0 then both `info.geometryCount` and `info.instanceCount` must be 0

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_ACCELERATION_STRUCTURE_CREATE_INFO_NV`
- `pNext` must be NULL
- `info` must be a valid `VkAccelerationStructureInfoNV` structure

The `VkAccelerationStructureInfoNV` structure is defined as:

typedef struct VkAccelerationStructureInfoNV {
    VkStructureType                        sType;
    const void*                            pNext;
    VkAccelerationStructureTypeNV          type;
    VkBuildAccelerationStructureFlagsNV    flags;
    uint32_t                               instanceCount;
    uint32_t                               geometryCount;
    const VkGeometryNV*                    pGeometries;
} VkAccelerationStructureInfoNV;

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `type` is a `VkAccelerationStructureTypeNV` value specifying the type of acceleration structure that will be created.
- `flags` is a bitmask of `VkBuildAccelerationStructureFlagBitsNV` specifying additional parameters of the acceleration structure.
• `instanceCount` specifies the number of instances that will be in the new acceleration structure.
• `geometryCount` specifies the number of geometries that will be in the new acceleration structure.
• `pGeometries` is a pointer to an array of `geometryCount` `VkGeometryNV` structures containing the scene data being passed into the acceleration structure.

`VkAccelerationStructureInfoNV` contains information that is used both for acceleration structure creation with `vkCreateAccelerationStructureNV` and in combination with the actual geometric data to build the acceleration structure with `vkCmdBuildAccelerationStructureNV`.

### Valid Usage

- `geometryCount` **must** be less than or equal to `VkPhysicalDeviceRayTracingPropertiesNV::maxGeometryCount`
- `instanceCount` **must** be less than or equal to `VkPhysicalDeviceRayTracingPropertiesNV::maxInstanceCount`
- The total number of triangles in all geometries **must** be less than or equal to `VkPhysicalDeviceRayTracingPropertiesNV::maxTriangleCount`
- If `type` is `VK_ACCELERATION_STRUCTURE_TYPE_TOP_LEVEL_NV` then `geometryCount` **must** be 0
- If `type` is `VK_ACCELERATION_STRUCTURE_TYPE_BOTTOM_LEVEL_NV` then `instanceCount` **must** be 0
- If `type` is `VK_ACCELERATION_STRUCTURE_TYPE_BOTTOM_LEVEL_NV` then the `geometryType` member of each geometry in `pGeometries` **must** be the same
- `flags` **must** be a valid combination of `VkBuildAccelerationStructureFlagBitsNV` values
- If `flags` has the `VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_TRACE_BIT_NV` bit set, then it **must** not have the `VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_BUILD_BIT_NV` bit set
- `scratch` **must** have been created with `VK_BUFFER_USAGE_RAY_TRACING_BIT_NV` usage flag
- If `instanceData` is not `VK_NULL_HANDLE`, `instanceData` **must** have been created with `VK_BUFFER_USAGE_RAY_TRACING_BIT_NV` usage flag

### Valid Usage (Implicit)

- `sType` **must** be `VK_STRUCTURE_TYPE_ACCELERATION_STRUCTURE_INFO_NV`
- `pNext` **must** be `NULL`
- `type` **must** be a valid `VkAccelerationStructureTypeNV` value
- `flags` **must** be 0
- If `geometryCount` is not 0, `pGeometries` **must** be a valid pointer to an array of `geometryCount` valid `VkGeometryNV` structures

To create an acceleration structure, call:
VkResult vkCreateAccelerationStructureKHR(
    VkDevice                                    device,
    const VkAccelerationStructureCreateInfoKHR* pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkAccelerationStructureKHR*                 pAccelerationStructure);

- **device** is the logical device that creates the buffer object.
- **pCreateInfo** is a pointer to a `VkAccelerationStructureCreateInfoKHR` structure containing parameters affecting creation of the acceleration structure.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pAccelerationStructure** is a pointer to a `VkAccelerationStructureKHR` handle in which the resulting acceleration structure object is returned.

Similar to other objects in Vulkan, the acceleration structure creation merely creates an object with a specific “shape”. The type and quantity of geometry that can be built into an acceleration structure is determined by the parameters of `VkAccelerationStructureCreateInfoKHR`.

Populating the data in the object after allocating and binding memory is done with commands such as `vkCmdBuildAccelerationStructureKHR`, `vkBuildAccelerationStructureKHR`, `vkCmdCopyAccelerationStructureKHR`, and `vkCopyAccelerationStructureKHR`.

The input buffers passed to acceleration structure build commands will be referenced by the implementation for the duration of the command. After the command completes, the acceleration structure may hold a reference to any acceleration structure specified by an active instance contained therein. Apart from this referencing, acceleration structures must be fully self-contained. The application may re-use or free any memory which was used by the command as an input or as scratch without affecting the results of ray traversal.

### Valid Usage

- The rayTracing or rayQuery feature must be enabled
- If `VkAccelerationStructureCreateInfoKHR::deviceAddress` is not zero, the rayTracingAccelerationStructureCaptureReplay feature must be enabled
- If `device` was created with multiple physical devices, then the bufferDeviceAddressMultiDevice feature must be enabled
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pCreateInfo** must be a valid pointer to a valid `VkAccelerationStructureCreateInfoKHR` structure
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid `VkAllocationCallbacks` structure
- **pAccelerationStructure** must be a valid pointer to a `VkAccelerationStructureKHR` handle

Return Codes

**Success**
- **VK_SUCCESS**

**Failure**
- **VK_ERROR_OUT_OF_HOST_MEMORY**
- **VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS_KHR**

The `VkAccelerationStructureCreateInfoKHR` structure is defined as:

```c
typedef struct VkAccelerationStructureCreateInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkDeviceSize compactedSize;
    VkAccelerationStructureTypeKHR type;
    VkBuildAccelerationStructureFlagsKHR flags;
    uint32_t maxGeometryCount;
    const VkAccelerationStructureCreateGeometryTypeInfoKHR* pGeometryInfos;
    VkDeviceAddress deviceAddress;
} VkAccelerationStructureCreateInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **compactedSize** is the size from the result of `vkCmdWriteAccelerationStructuresPropertiesKHR` if this acceleration structure is going to be the target of a compacting copy.
- **type** is a `VkAccelerationStructureTypeKHR` value specifying the type of acceleration structure that will be created.
- **flags** is a bitmask of `VkBuildAccelerationStructureFlagBitsKHR` specifying additional parameters of the acceleration structure.
- **maxGeometryCount** specifies the number of geometries that will be in the new acceleration structure.
• `pGeometryInfos` is an array of `maxGeometryCount` `VkAccelerationStructureCreateGeometryTypeInfoKHR` structures, which describe the maximum size and format of the data that will be built into the acceleration structure.

• `deviceAddress` is the device address requested for the acceleration structure if the `rayTracingAccelerationStructureCaptureReplay` feature is being used.

If `deviceAddress` is zero, no specific address is requested.

If `deviceAddress` is not zero, `deviceAddress` **must** be an address retrieved from an identically created acceleration structure on the same implementation. The acceleration structure **must** also be bound to an identically created `VkDeviceMemory` object.

Apps **should** avoid creating acceleration structures with app-provided addresses and implementation-provided addresses in the same process, to reduce the likelihood of `VK_ERROR_INVALID_OPAQUE_CAPTURE_ADDRESS_KHR` errors.

### Valid Usage

- If `compactedSize` is not 0 then `maxGeometryCount` **must** be 0
- If `compactedSize` is 0 then `maxGeometryCount` **must** not be 0
- If `type` is `VK_ACCELERATION_STRUCTURE_TYPE_BOTTOM_LEVEL_KHR` then `maxGeometryCount` **must** be less than or equal to `VkPhysicalDeviceRayTracingPropertiesKHR::maxGeometryCount`
- If `type` is `VK_ACCELERATION_STRUCTURE_TYPE_TOP_LEVEL_KHR` then the `maxPrimitiveCount` member of each element of the `pGeometryInfos` array **must** be less than or equal to `VkPhysicalDeviceRayTracingPropertiesKHR::maxInstanceCount`
- The total number of triangles in all geometries **must** be less than or equal to `VkPhysicalDeviceRayTracingPropertiesKHR::maxPrimitiveCount`
- The total number of AABBs in all geometries **must** be less than or equal to `VkPhysicalDeviceRayTracingPropertiesKHR::maxPrimitiveCount`
- If `type` is `VK_ACCELERATION_STRUCTURE_TYPE_TOP_LEVEL_KHR` and `compactedSize` is 0, `maxGeometryCount` **must** be 1
- If `type` is `VK_ACCELERATION_STRUCTURE_TYPE_TOP_LEVEL_KHR` and `compactedSize` is 0, the `geometryType` member of elements of `pGeometryInfos` **must** be `VK_GEOMETRY_TYPE_INSTANCES_KHR`
- If `type` is `VK_ACCELERATION_STRUCTURE_TYPE_BOTTOM_LEVEL_KHR` and `compactedSize` is 0, the `geometryType` member of elements of `pGeometryInfos` **must** not be `VK_GEOMETRY_TYPE_INSTANCES_KHR`
- If `type` is `VK_ACCELERATION_STRUCTURE_TYPE_BOTTOM_LEVEL_KHR` then the `geometryType` member of each geometry in `pGeometryInfos` **must** be the same
- If `flags` has the `VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_TRACE_BIT_KHR` bit set, then it **must** not have the `VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_BUILD_BIT_KHR` bit set
- If `deviceAddress` is not 0, `VkPhysicalDeviceRayTracingFeaturesKHR::rayTracingAccelerationStructureCaptureReplay` **must** be `VK_TRUE`
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_ACCELERATION_STRUCTURE_CREATE_INFO_KHR`
- `pNext` must be `NULL`
- `type` must be a valid `VkAccelerationStructureTypeKHR` value
- `flags` must be a valid combination of `VkBuildAccelerationStructureFlagBitsKHR` values
- If `maxGeometryCount` is not 0, `pGeometryInfos` must be a valid pointer to an array of `maxGeometryCount` valid `VkAccelerationStructureCreateGeometryTypeInfoKHR` structures

The `VkAccelerationStructureCreateGeometryTypeInfoKHR` structure specifies the shape of geometries that will be built into an acceleration structure and is defined as:

```c
typedef struct VkAccelerationStructureCreateGeometryTypeInfoKHR {
    VkStructureType      sType;
    const void*          pNext;
    VkGeometryTypeKHR    geometryType;
    uint32_t             maxPrimitiveCount;
    VkIndexType          indexType;
    uint32_t             maxVertexCount;
    VkFormat             vertexFormat;
    VkBool32             allowsTransforms;
} VkAccelerationStructureCreateGeometryTypeInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `geometryType` is a `VkGeometryTypeKHR` that describes the type of an acceleration structure geometry.
- `maxPrimitiveCount` describes the maximum number of primitives that can be built into an acceleration structure geometry.
- `indexType` is a `VkIndexType` that describes the index type used to build this geometry when `geometryType` is `VK_GEOMETRY_TYPE_TRIANGLES_KHR`.
- `maxVertexCount` describes the maximum vertex count that can be used to build an acceleration structure geometry when `geometryType` is `VK_GEOMETRY_TYPE_TRIANGLES_KHR`.
- `vertexFormat` is a `VkFormat` that describes the vertex format used to build this geometry when `geometryType` is `VK_GEOMETRY_TYPE_TRIANGLES_KHR`.
- `allowsTransforms` indicates whether transform data can be used by this acceleration structure or not, when `geometryType` is `VK_GEOMETRY_TYPE_TRIANGLES_KHR`.

When `geometryType` is `VK_GEOMETRY_TYPE_TRIANGLES_KHR`:

- If `indexType` is `VK_INDEX_TYPE_NONE_KHR`, then this structure describes a set of triangles.
- If `indexType` is not `VK_INDEX_TYPE_NONE_KHR`, then this structure describes a set of indexed
Valid Usage

- If `geometryType` is `VK_GEOMETRY_TYPE_TRIANGLES_KHR`, `vertexFormat` must support the `VK_FORMAT_FEATURE_ACCELERATION_STRUCTURE_VERTEX_BUFFER_BIT_KHR` in `VkFormatProperties::bufferFeatures` as returned by `vkGetPhysicalDeviceFormatProperties2`.

- If `geometryType` is `VK_GEOMETRY_TYPE_TRIANGLES_KHR`, `indexType` must be `VK_INDEX_TYPE_UINT16`, `VK_INDEX_TYPE_UINT32`, or `VK_INDEX_TYPE_NONE_KHR`.

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_ACCELERATION_STRUCTURE_CREATE_GEOMETRY_TYPE_INFO_KHR`.
- `pNext` must be `NULL`.
- `geometryType` must be a valid `VkGeometryTypeKHR` value.
- `indexType` must be a valid `VkIndexType` value.
- If `vertexFormat` is not `0`, `vertexFormat` must be a valid `VkFormat` value.

Values which can be set in `VkAccelerationStructureCreateInfoKHR::type` or `VkAccelerationStructureInfoNV::type` specifying the type of acceleration structure, are:

```c
typedef enum VkAccelerationStructureTypeKHR {
    VK_ACCELERATION_STRUCTURE_TYPE_TOP_LEVEL_KHR = 0,
    VK_ACCELERATION_STRUCTURE_TYPE_BOTTOM_LEVEL_KHR = 1,
    VK_ACCELERATION_STRUCTURE_TYPE_TOP_LEVEL_NV =
    VK_ACCELERATION_STRUCTURE_TYPE_TOP_LEVEL_KHR,
    VK_ACCELERATION_STRUCTURE_TYPE_BOTTOM_LEVEL_NV =
    VK_ACCELERATION_STRUCTURE_TYPE_BOTTOM_LEVEL_KHR,
} VkAccelerationStructureTypeKHR;
```

or the equivalent

```c
typedef VkAccelerationStructureTypeKHR VkAccelerationStructureTypeNV;
```

- `VK_ACCELERATION_STRUCTURE_TYPE_TOP_LEVEL_KHR` is a top-level acceleration structure containing instance data referring to bottom-level acceleration structures.

- `VK_ACCELERATION_STRUCTURE_TYPE_BOTTOM_LEVEL_KHR` is a bottom-level acceleration structure containing the AABBs or geometry to be intersected.

Bits which can be set in `VkAccelerationStructureCreateInfoKHR::flags` or `VkAccelerationStructureInfoNV::flags` specifying additional parameters for acceleration structure builds, are:
typedef enum VkBuildAccelerationStructureFlagBitsKHR {
    VK_BUILD_ACCELERATION_STRUCTURE_ALLOW_UPDATE_BIT_KHR = 0x00000001,
    VK_BUILD_ACCELERATION_STRUCTURE_ALLOW_COMPACTION_BIT_KHR = 0x00000002,
    VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_TRACE_BIT_KHR = 0x00000004,
    VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_BUILD_BIT_KHR = 0x00000008,
    VK_BUILD_ACCELERATION_STRUCTURE_LOW_MEMORY_BIT_KHR = 0x00000010,
    VK_BUILD_ACCELERATION_STRUCTURE_ALLOW_UPDATE_BIT_NV =
    VK_BUILD_ACCELERATION_STRUCTURE_ALLOW_COMPACTION_BIT_NV =
    VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_TRACE_BIT_NV =
    VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_BUILD_BIT_NV =
    VK_BUILD_ACCELERATION_STRUCTURE_LOW_MEMORY_BIT_NV =
} VkBuildAccelerationStructureFlagBitsKHR;

or the equivalent

typedef VkBuildAccelerationStructureFlagBitsKHR
VkBuildAccelerationStructureFlagBitsNV;

• VK_BUILD_ACCELERATION_STRUCTURE_ALLOW_UPDATE_BIT_KHR indicates that the specified acceleration structure can be updated with update of VK_TRUE in vkCmdBuildAccelerationStructureKHR or vkCmdBuildAccelerationStructureNV.

• VK_BUILD_ACCELERATION_STRUCTURE_ALLOW_COMPACTION_BIT_KHR indicates that the specified acceleration structure can act as the source for a copy acceleration structure command with mode of VK_COPY_ACCELERATION_STRUCTURE_MODE_COMPACT_KHR to produce a compacted acceleration structure.

• VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_TRACE_BIT_KHR indicates that the given acceleration structure build should prioritize trace performance over build time.

• VK_BUILD_ACCELERATION_STRUCTURE_PREFER_FAST_BUILD_BIT_KHR indicates that the given acceleration structure build should prioritize build time over trace performance.

• VK_BUILD_ACCELERATION_STRUCTURE_LOW_MEMORY_BIT_KHR indicates that this acceleration structure should minimize the size of the scratch memory and the final result build, potentially at the expense of build time or trace performance.

Note

VK_BUILD_ACCELERATION_STRUCTURE_ALLOW_UPDATE_BIT_KHR and
VK_BUILD_ACCELERATION_STRUCTURE_ALLOW_COMPACTION_BIT_KHR may take more time and memory than a normal build, and so should only be used when those features are needed.
typedef VkFlags VkBuildAccelerationStructureFlagsKHR;

or the equivalent

typedef VkBuildAccelerationStructureFlagsKHR VkBuildAccelerationStructureFlagsNV;

VkBuildAccelerationStructureFlagsKHR is a bitmask type for setting a mask of zero or more VkBuildAccelerationStructureFlagBitsKHR.

The VkGeometryNV structure describes geometry in a bottom-level acceleration structure and is defined as:

typedef struct VkGeometryNV {
    VkStructureType sType;
    const void* pNext;
    VkGeometryTypeKHR geometryType;
    VkGeometryDataNV geometry;
    VkGeometryFlagsKHR flags;
} VkGeometryNV;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **geometryType** specifies the VkGeometryTypeKHR which this geometry refers to.
- **geometry** contains the geometry data as described in VkGeometryDataNV.
- **flags** has VkGeometryFlagBitsKHR describing options for this geometry.

### Valid Usage

- **geometryType** must be `VK_GEOMETRY_TYPE_TRIANGLES_NV` or `VK_GEOMETRY_TYPE_AABBS_NV`

### Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_GEOMETRY_NV`
- **pNext** must be NULL
- **geometryType** must be a valid VkGeometryTypeKHR value
- **geometry** must be a valid VkGeometryDataNV structure
- **flags** must be a valid combination of VkGeometryFlagBitsKHR values

Geometry types are specified by VkGeometryTypeKHR, which takes values:
typedef enum VkGeometryTypeKHR {
    VK_GEOMETRY_TYPE_TRIANGLES_KHR = 0,
    VK_GEOMETRY_TYPE_AABBS_KHR = 1,
    VK_GEOMETRY_TYPE_INSTANCES_KHR = 1000150000,
    VK_GEOMETRY_TYPE_TRIANGLES_NV = VK_GEOMETRY_TYPE_TRIANGLES_KHR,
    VK_GEOMETRY_TYPE_AABBS_NV = VK_GEOMETRY_TYPE_AABBS_KHR,
} VkGeometryTypeKHR;

or the equivalent

typedef VkGeometryTypeKHR VkGeometryTypeNV;

• VK_GEOMETRY_TYPE_TRIANGLES_KHR specifies a geometry type consisting of triangles.
• VK_GEOMETRY_TYPE_AABBS_KHR specifies a geometry type consisting of axis-aligned bounding boxes.
• VK_GEOMETRY_TYPE_INSTANCES_KHR specifies a geometry type consisting of acceleration structure instances.

Bits specifying additional parameters for geometries in acceleration structure builds, are:

typedef enum VkGeometryFlagBitsKHR {
    VK_GEOMETRY_OPAQUE_BIT_KHR = 0x00000001,
    VK_GEOMETRY_NO_DUPLICATE_ANY_HIT_INVOCATION_BIT_KHR = 0x00000002,
    VK_GEOMETRY_OPAQUE_BIT_NV = VK_GEOMETRY_OPAQUE_BIT_KHR,
    VK_GEOMETRY_NO_DUPLICATE_ANY_HIT_INVOCATION_BIT_NV = VK_GEOMETRY_NO_DUPLICATE_ANY_HIT_INVOCATION_BIT_KHR,
} VkGeometryFlagBitsKHR;

or the equivalent

typedef VkGeometryFlagBitsKHR VkGeometryFlagBitsNV;

• VK_GEOMETRY_OPAQUE_BIT_KHR indicates that this geometry does not invoke the any-hit shaders even if present in a hit group.
• VK_GEOMETRY_NO_DUPLICATE_ANY_HIT_INVOCATION_BIT_KHR indicates that the implementation must only call the any-hit shader a single time for each primitive in this geometry. If this bit is absent an implementation may invoke the any-hit shader more than once for this geometry.
**VkGeometryFlagsKHR** is a bitmask type for setting a mask of zero or more **VkGeometryFlagBitsKHR**.

The **VkGeometryDataNV** structure specifies geometry in a bottom-level acceleration structure and is defined as:

```c
typedef struct VkGeometryDataNV {
    VkGeometryTrianglesNV    triangles;
    VkGeometryAABBNV         aabbs;
} VkGeometryDataNV;
```

- **triangles** contains triangle data if **VkGeometryNV::geometryType** is **VK_GEOMETRY_TYPE_TRIANGLES_NV**.
- **aabbs** contains axis-aligned bounding box data if **VkGeometryNV::geometryType** is **VK_GEOMETRY_TYPE_AABBS_NV**.

### Valid Usage (Implicit)

- **triangles** must be a valid **VkGeometryTrianglesNV** structure.
- **aabbs** must be a valid **VkGeometryAABBNV** structure.

The **VkGeometryTrianglesNV** structure specifies triangle geometry in a bottom-level acceleration structure and is defined as:

```c
typedef struct VkGeometryTrianglesNV {
    VkStructureType    sType;
    const void*        pNext;
    VkBuffer           vertexData;
    VkDeviceSize       vertexOffset;
    uint32_t           vertexCount;
    VkDeviceSize       vertexStride;
    VkFormat           vertexFormat;
    VkBuffer           indexData;
    VkDeviceSize       indexOffset;
    uint32_t           indexCount;
    VkIndexType        indexType;
    VkBuffer           transformData;
    VkDeviceSize       transformOffset;
} VkGeometryTrianglesNV;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **vertexData** is the buffer containing vertex data for this geometry.
- **vertexOffset** is the offset in bytes within **vertexData** containing vertex data for this geometry.
- **vertexCount** is the number of valid vertices.
• **vertexStride** is the stride in bytes between each vertex.
• **vertexFormat** is a [VkFormat](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkFormat.html) describing the format of each vertex element.
• **indexData** is the buffer containing index data for this geometry.
• **indexOffset** is the offset in bytes within **indexData** containing index data for this geometry.
• **indexCount** is the number of indices to include in this geometry.
• **indexType** is a [VkIndexType](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkIndexType.html) describing the format of each index.
• **transformData** is an optional buffer containing an [VkTransformMatrixNV](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkTransformMatrixNV.html) structure defining a transformation to be applied to this geometry.
• **transformOffset** is the offset in bytes in **transformData** of the transform information described above.

If **IndexOfType** is **VK_INDEX_TYPE_NONE_NV**, then this structure describes a set of triangles determined by **vertexCount**. Otherwise, this structure describes a set of indexed triangles determined by **indexCount**.

---

**Valid Usage**

- **vertexOffset** **must** be less than the size of **vertexData**
- **vertexOffset** **must** be a multiple of the component size of **vertexFormat**
- **indexOffset** **must** be less than the size of **indexData**
- **indexOffset** **must** be a multiple of the element size of **indexType**
- **indexType** **must** be [VK_INDEX_TYPE_UINT16](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkIndexType_UINT16.html), [VK_INDEX_TYPE_UINT32](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkIndexType_UINT32.html), or [VK_INDEX_TYPE_NONE_NV](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkIndexType_NONE_NV.html)
- **indexData** **must** be [VK_NULL_HANDLE](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkBuffer.html) if **indexType** is [VK_INDEX_TYPE_NONE_NV](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkIndexType_NONE_NV.html)
- **indexData** **must** be a valid VkBuffer handle if **indexType** is not [VK_INDEX_TYPE_NONE_NV](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkIndexType_NONE_NV.html)
- **indexCount** **must** be 0 if **indexType** is [VK_INDEX_TYPE_NONE_NV](https://www.khronos.org/registry/vulkan/specs/1.2-extensions/man/htmlVkIndexType_NONE_NV.html)
- **transformOffset** **must** be less than the size of **transformData**
- **transformOffset** **must** be a multiple of 16
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_GEOMETRY_TRIANGLES_NV`
- **pNext** must be `NULL`
- If `vertexData` is not `VK_NULL_HANDLE`, `vertexData` must be a valid `VkBuffer` handle
- **vertexFormat** must be a valid `VkFormat` value
- If `indexData` is not `VK_NULL_HANDLE`, `indexData` must be a valid `VkBuffer` handle
- **indexType** must be a valid `VkIndexType` value
- If `transformData` is not `VK_NULL_HANDLE`, `transformData` must be a valid `VkBuffer` handle
- Each of `indexData`, `transformData`, and `vertexData` that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`

The `VkGeometryAABBNV` structure specifies axis-aligned bounding box geometry in a bottom-level acceleration structure, and is defined as:

```c
typedef struct VkGeometryAABBNV {
    VkStructureType    sType;
    const void*        pNext;
    VkBuffer           aabbData;
    uint32_t           numAABBs;
    uint32_t           stride;
    VkDeviceSize       offset;
} VkGeometryAABBNV;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **aabbData** is the buffer containing axis-aligned bounding box data.
- **numAABBs** is the number of AABBs in this geometry.
- **stride** is the stride in bytes between AABBs in `aabbData`.
- **offset** is the offset in bytes of the first AABB in `aabbData`.

The AABB data in memory is six 32-bit floats consisting of the minimum x, y, and z values followed by the maximum x, y, and z values.

Valid Usage

- **offset** must be less than the size of `aabbData`
- **offset** must be a multiple of 8
- **stride** must be a multiple of 8
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_GEOMETRY_AABB_NV`
- `pNext` must be `NULL`
- If `aabbData` is not `VK_NULL_HANDLE`, `aabbData` must be a valid `VkBuffer` handle

To destroy an acceleration structure, call:

```c
void vkDestroyAccelerationStructureKHR(
    VkDevice device, 
    VkAccelerationStructureKHR accelerationStructure, 
    const VkAllocationCallbacks* pAllocator);
```

or the equivalent command

```c
void vkDestroyAccelerationStructureNV(
    VkDevice device, 
    VkAccelerationStructureKHR accelerationStructure, 
    const VkAllocationCallbacks* pAllocator);
```

- `device` is the logical device that destroys the buffer.
- `accelerationStructure` is the acceleration structure to destroy.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

Valid Usage

- All submitted commands that refer to `accelerationStructure` must have completed execution
- If `VkAllocationCallbacks` were provided when `accelerationStructure` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `accelerationStructure` was created, `pAllocator` must be `NULL`
Valid Usage (Implicit)

- **device** must be a valid *VkDevice* handle
- If *accelerationStructure* is not *VK_NULL_HANDLE*, *accelerationStructure* must be a valid *VkAccelerationStructureKHR* handle
- If *pAllocator* is not NULL, *pAllocator* must be a valid pointer to a valid *VkAllocationCallbacks* structure
- If *accelerationStructure* is a valid handle, it must have been created, allocated, or retrieved from *device*

Host Synchronization

- Host access to *accelerationStructure* must be externally synchronized

An acceleration structure has memory requirements for the structure object itself, scratch space for the build, and scratch space for the update.

Scratch space is allocated as a *VkBuffer*, so for

\[
\text{VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_BUILD_SCRATCH_NV}
\]

and

\[
\text{VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_UPDATE_SCRATCH_NV}
\]

the *pMemoryRequirements->alignment* and *pMemoryRequirements->memoryTypeBits* values returned by this call must be filled with zero, and should be ignored by the application.

To query the memory requirements call:

```c
void vkGetAccelerationStructureMemoryRequirementsNV(
    VkDevice device,
    const VkAccelerationStructureMemoryRequirementsInfoNV* pInfo,
    VkMemoryRequirements2KHR* pMemoryRequirements);
```

- *device* is the logical device on which the acceleration structure was created.
- *pInfo* specifies the acceleration structure to get memory requirements for.
- *pMemoryRequirements* returns the requested acceleration structure memory requirements.

Valid Usage (Implicit)

- **device** must be a valid *VkDevice* handle
- **pInfo** must be a valid pointer to a valid *VkAccelerationStructureMemoryRequirementsInfoNV* structure
- **pMemoryRequirements** must be a valid pointer to a *VkMemoryRequirements2KHR* structure

The *VkAccelerationStructureMemoryRequirementsInfoNV* structure is defined as:
typedef struct VkAccelerationStructureMemoryRequirementsInfoNV {
    VkStructureType                                    sType;
    const void*                                        pNext;
    VkAccelerationStructureMemoryRequirementsTypeNV    type;
    VkAccelerationStructureNV                          accelerationStructure;
} VkAccelerationStructureMemoryRequirementsInfoNV;

• **sType** is the type of this structure.

• **pNext** is **NULL** or a pointer to an extension-specific structure.

• **type** selects the type of memory requirement being queried. 
  - VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_NV returns the memory requirements for the object itself.
  - VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_BUILD_SCRATCH_NV returns the memory requirements for the scratch memory when doing a build.
  - VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_UPDATE_SCRATCH_NV returns the memory requirements for the scratch memory when doing an update.

• **accelerationStructure** is the acceleration structure to be queried for memory requirements.

### Valid Usage (Implicit)

- **sType** must be VK_STRUCTURE_TYPE_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_INFO_NV
- **pNext** must be **NULL**
- **type** must be a valid VkAccelerationStructureMemoryRequirementsTypeNV value
- **accelerationStructure** must be a valid VkAccelerationStructureNV handle

An acceleration structure has memory requirements for the structure object itself, scratch space for the build, and scratch space for the update.

Scratch space is allocated as a VkBuffer, so for VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_BUILD_SCRATCH_KHR and VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_UPDATE_SCRATCH_KHR the pMemoryRequirements->alignment and pMemoryRequirements->memoryTypeBits values returned by this call must be filled with zero, and should be ignored by the application.

To query the memory requirements call:

```c
void vkGetAccelerationStructureMemoryRequirementsKHR(
    VkDevice                                    device,
    const VkAccelerationStructureMemoryRequirementsInfoKHR* pInfo,
    VkMemoryRequirements2*                     pMemoryRequirements);
```

- **device** is the logical device on which the acceleration structure was created.
- **pInfo** specifies the acceleration structure to get memory requirements for.
• `pMemoryRequirements` returns the requested acceleration structure memory requirements.

**Valid Usage (Implicit)**

- `device` must be a valid `VkDevice` handle
- `pInfo` must be a valid pointer to a valid `VkAccelerationStructureMemoryRequirementsInfoKHR` structure
- `pMemoryRequirements` must be a valid pointer to a `VkMemoryRequirements2` structure

The `VkAccelerationStructureMemoryRequirementsInfoKHR` structure is defined as:

```c
typedef struct VkAccelerationStructureMemoryRequirementsInfoKHR {
    VkStructureType                                     sType;
    const void*                                         pNext;
    VkAccelerationStructureMemoryRequirementsTypeKHR    type;
    VkAccelerationStructureBuildTypeKHR                 buildType;
    VkAccelerationStructureKHR                          accelerationStructure;
} VkAccelerationStructureMemoryRequirementsInfoKHR;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `buildType` selects the build types whose memory requirements are being queried.
- `type` selects the type of memory requirement being queried. `VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_KHR` returns the memory requirements for the object itself. `VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_BUILD_SCRATCH_KHR` returns the memory requirements for the scratch memory when doing a build. `VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_UPDATE_SCRATCH_KHR` returns the memory requirements for the scratch memory when doing an update.
- `accelerationStructure` is the acceleration structure to be queried for memory requirements.

**Valid Usage (Implicit)**

- `sType` must be `VK_STRUCTURE_TYPE_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_INFO_KHR`
- `pNext` must be `NULL`
- `type` must be a valid `VkAccelerationStructureMemoryRequirementsTypeKHR` value
- `buildType` must be a valid `VkAccelerationStructureBuildTypeKHR` value
- `accelerationStructure` must be a valid `VkAccelerationStructureKHR` handle

Possible values of `type` in `VkAccelerationStructureMemoryRequirementsInfoKHR` are:
typedef enum VkAccelerationStructureMemoryRequirementsTypeKHR {
    VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_KHR = 0,
    VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_BUILD_SCRATCH_KHR = 1,
    VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_UPDATE_SCRATCH_KHR = 2,
    VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_NV =
    VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_KHR,
    VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_BUILD_SCRATCH_NV =
    VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_BUILD_SCRATCH_KHR,
    VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_UPDATE_SCRATCH_NV =
    VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_UPDATE_SCRATCH_KHR,
} VkAccelerationStructureMemoryRequirementsTypeKHR;

or the equivalent

typedef VkAccelerationStructureMemoryRequirementsTypeKHR
    VkAccelerationStructureMemoryRequirementsTypeNV;

• VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_KHR requests the memory requirement for the VkAccelerationStructureKHR backing store.

• VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_BUILD_SCRATCH_KHR requests the memory requirement for scratch space during the initial build.

• VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_UPDATE_SCRATCH_KHR requests the memory requirement for scratch space during an update.

Possible values of buildType in VkAccelerationStructureMemoryRequirementsInfoKHR are:

typedef enum VkAccelerationStructureBuildTypeKHR {
    VK_ACCELERATION_STRUCTURE_BUILD_TYPE_HOST_KHR = 0,
    VK_ACCELERATION_STRUCTURE_BUILD_TYPE_DEVICE_KHR = 1,
    VK_ACCELERATION_STRUCTURE_BUILD_TYPE_HOST_OR_DEVICE_KHR = 2,
} VkAccelerationStructureBuildTypeKHR;

• VK_ACCELERATION_STRUCTURE_BUILD_TYPE_HOST_KHR requests the memory requirement for operations performed by the host.

• VK_ACCELERATION_STRUCTURE_BUILD_TYPE_DEVICE_KHR requests the memory requirement for operations performed by the device.

• VK_ACCELERATION_STRUCTURE_BUILD_TYPE_HOST_OR_DEVICE_KHR requests the memory requirement for operations performed by either the host, or the device.

The implementation guarantees certain properties about the memory requirements returned by vkGetAccelerationStructureMemoryRequirementsKHR called with a type of VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_KHR:

• The memoryTypeBits member always contains at least one bit set.

• The memoryTypeBits member is identical for all VkAccelerationStructureKHR objects created with
the same value for the type and flags members in the VkAccelerationStructureCreateInfoKHR structure passed to vkCreateAccelerationStructureKHR and with the same value for buildType in VkAccelerationStructureMemoryRequirementsInfoKHR passed to vkGetAccelerationStructureMemoryRequirementsKHR.

To attach memory to one or more acceleration structures at a time, call:

```
VkResult vkBindAccelerationStructureMemoryKHR(
    VkDevice                                    device,  
    uint32_t                                    bindInfoCount,  
    const VkBindAccelerationStructureMemoryInfoKHR* pBindInfos);
```

or the equivalent command

```
VkResult vkBindAccelerationStructureMemoryNV(
    VkDevice                                    device,  
    uint32_t                                    bindInfoCount,  
    const VkBindAccelerationStructureMemoryInfoKHR* pBindInfos);
```

- **device** is the logical device that owns the acceleration structures and memory.
- **bindInfoCount** is the number of elements in **pBindInfos**.
- **pBindInfos** is a pointer to an array of VkBindAccelerationStructureMemoryInfoKHR structures describing acceleration structures and memory to bind.

**Valid Usage (Implicit)**

- **device** must be a valid VkDevice handle
- **pBindInfos** must be a valid pointer to an array of bindInfoCount valid VkBindAccelerationStructureMemoryInfoKHR structures
- **bindInfoCount** must be greater than 0

**Return Codes**

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

The VkBindAccelerationStructureMemoryInfoKHR structure is defined as:
typedef struct VkBindAccelerationStructureMemoryInfoKHR {
    VkStructureType               sType;
    const void*                   pNext;
    VkAccelerationStructureKHR    accelerationStructure;
    VkDeviceMemory                memory;
    VkDeviceSize                  memoryOffset;
    uint32_t                      deviceIndexCount;
    const uint32_t*               pDeviceIndices;
} VkBindAccelerationStructureMemoryInfoKHR;

or the equivalent

typedef VkBindAccelerationStructureMemoryInfoKHR
     VkBindAccelerationStructureMemoryInfoNV;

• **sType** is the type of this structure.

• **pNext** is NULL or a pointer to an extension-specific structure.

• **accelerationStructure** is the acceleration structure to be attached to memory.

• **memory** is a **VkDeviceMemory** object describing the device memory to attach.

• **memoryOffset** is the start offset of the region of memory that is to be bound to the acceleration structure. The number of bytes returned in the **VkMemoryRequirements::size** member in **memory**, starting from **memoryOffset** bytes, will be bound to the specified acceleration structure.

• **deviceIndexCount** is the number of elements in **pDeviceIndices**.

• **pDeviceIndices** is a pointer to an array of device indices.

---

**Valid Usage**

• **accelerationStructure** must not already be backed by a memory object

• **memoryOffset** must be less than the size of **memory**

• **memory** must have been allocated using one of the memory types allowed in the **memoryTypeBits** member of the **VkMemoryRequirements** structure returned from a call to **vkGetAccelerationStructureMemoryRequirementsKHR** with **accelerationStructure** and type of **VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_KHR**

• **memoryOffset** must be an integer multiple of the **alignment** member of the **VkMemoryRequirements** structure returned from a call to **vkGetAccelerationStructureMemoryRequirementsKHR** with **accelerationStructure** and type of **VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_KHR**

• The **size** member of the **VkMemoryRequirements** structure returned from a call to **vkGetAccelerationStructureMemoryRequirementsKHR** with **accelerationStructure** and type of **VK_ACCELERATION_STRUCTURE_MEMORY_REQUIREMENTS_TYPE_OBJECT_KHR** must be less than or equal to the size of **memory** minus **memoryOffset**
Valid Usage (Implicit)

- `sType must` be `VK_STRUCTURE_TYPE_BIND_ACCELERATION_STRUCTURE_MEMORY_INFO_KHR`
- `pNext must` be `NULL`
- `accelerationStructure must` be a valid `VkAccelerationStructureKHR` handle
- `memory must` be a valid `VkDeviceMemory` handle
- If `deviceIndexCount` is not 0, `pDeviceIndices must` be a valid pointer to an array of `deviceIndexCount uint32_t` values
- Both of `accelerationStructure`, and `memory must` have been created, allocated, or retrieved from the same `VkDevice`

To allow constructing geometry instances with device code if desired, we need to be able to query a opaque handle for an acceleration structure. This handle is a value of 8 bytes. To get this handle, call:

```cpp
VkResult vkGetAccelerationStructureHandleNV(
    VkDevice                                    device,
    VkAccelerationStructureKHR                  accelerationStructure,
    size_t                                      dataSize,
    void*                                       pData);
```

- `device` is the logical device that owns the acceleration structures.
- `accelerationStructure` is the acceleration structure.
- `dataSize` is the size in bytes of the buffer pointed to by `pData`.
- `pData` is a pointer to a user-allocated buffer where the results will be written.

Valid Usage

- `dataSize must` be large enough to contain the result of the query, as described above
- `accelerationStructure must` be bound completely and contiguously to a single `VkDeviceMemory` object via `vkBindAccelerationStructureMemoryKHR`

Valid Usage (Implicit)

- `device must` be a valid `VkDevice` handle
- `accelerationStructure must` be a valid `VkAccelerationStructureKHR` handle
- `pData must` be a valid pointer to an array of `dataSize` bytes
- `dataSize must` be greater than 0
- `accelerationStructure must` have been created, allocated, or retrieved from `device`
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

To query the 64-bit device address for an acceleration structure, call:

```c
VkDeviceAddress vkGetAccelerationStructureDeviceAddressKHR(
    VkDevice device,
    const VkAccelerationStructureDeviceAddressInfoKHR* pInfo);
```

• `device` is the logical device that the acceleration structure was created on.
• `pInfo` is a pointer to a `VkAccelerationStructureDeviceAddressInfoKHR` structure specifying the acceleration structure to retrieve an address for.

The 64-bit return value is an address of the acceleration structure, which can be used for device and shader operations that involve acceleration structures, such as ray traversal and acceleration structure building.

If the acceleration structure was created with a non-zero value of `VkAccelerationStructureCreateInfoKHR::deviceAddress` the return value will be the same address.

Valid Usage

• If `device` was created with multiple physical devices, then the `bufferDeviceAddressMultiDevice` feature must be enabled

Valid Usage (Implicit)

• `device` must be a valid `VkDevice` handle
• `pInfo` must be a valid pointer to a valid `VkAccelerationStructureDeviceAddressInfoKHR` structure

The `VkAccelerationStructureDeviceAddressInfoKHR` structure is defined as:
typedef struct VkAccelerationStructureDeviceAddressInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkAccelerationStructureKHR accelerationStructure;
} VkAccelerationStructureDeviceAddressInfoKHR;

• **sType** is the type of this structure.
• **pNext** is **NULL** or a pointer to an extension-specific structure.
• **accelerationStructure** specifies the acceleration structure whose address is being queried.

### Valid Usage

### Valid Usage (Implicit)

• **sType** must be **VK_STRUCTURE_TYPE_ACCELERATION_STRUCTURE_DEVICE_ADDRESS_INFO_KHR**
• **pNext** must be **NULL**
• **accelerationStructure** must be a valid **VkAccelerationStructureKHR** handle
Chapter 12. Samplers

VkSampler objects represent the state of an image sampler which is used by the implementation to read image data and apply filtering and other transformations for the shader.

Samplers are represented by VkSampler handles:

\[
\text{VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkSampler)}
\]

To create a sampler object, call:

\[
\text{VkResult vkCreateSampler(}
\quad \text{VkDevice device,}
\quad \text{const VkSamplerCreateInfo* pCreateInfo,}
\quad \text{const VkAllocationCallbacks* pAllocator,}
\quad \text{VkSampler* pSampler);}
\]

- **device** is the logical device that creates the sampler.
- **pCreateInfo** is a pointer to a VkSamplerCreateInfo structure specifying the state of the sampler object.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pSampler** is a pointer to a VkSampler handle in which the resulting sampler object is returned.

Valid Usage (Implicit)

- **device** must be a valid VkDevice handle
- **pCreateInfo** must be a valid pointer to a valid VkSamplerCreateInfo structure
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid VkAllocationCallbacks structure
- **pSampler** must be a valid pointer to a VkSampler handle

Return Codes

Success

- VK_SUCCESS

Failure

- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_TOO_MANY_OBJECTS
The `VkSamplerCreateInfo` structure is defined as:

```c
typedef struct VkSamplerCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkSamplerCreateFlags flags;
    VkFilter magFilter;
    VkFilter minFilter;
    VkSamplerMipmapMode.mipmapMode;
    VkSamplerAddressMode.addressModeU;
    VkSamplerAddressMode.addressModeV;
    VkSamplerAddressMode.addressModeW;
    float mipLodBias;
    VkBool32 anisotropyEnable;
    float maxAnisotropy;
    VkBool32 compareEnable;
    VkCompareOp compareOp;
    float minLod;
    float maxLod;
    VkBorderColor borderColor;
    VkBool32 unnormalizedCoordinates;
} VkSamplerCreateInfo;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `flags` is a bitmask of `VkSamplerCreateFlagBits` describing additional parameters of the sampler.
- `magFilter` is a `VkFilter` value specifying the magnification filter to apply to lookups.
- `minFilter` is a `VkFilter` value specifying the minification filter to apply to lookups.
- `mipmapMode` is a `VkSamplerMipmapMode` value specifying the mipmap filter to apply to lookups.
- `addressModeU` is a `VkSamplerAddressMode` value specifying the addressing mode for outside [0..1] range for U coordinate.
- `addressModeV` is a `VkSamplerAddressMode` value specifying the addressing mode for outside [0..1] range for V coordinate.
- `addressModeW` is a `VkSamplerAddressMode` value specifying the addressing mode for outside [0..1] range for W coordinate.
- `mipLodBias` is the bias to be added to mipmap LOD (level-of-detail) calculation and bias provided by image sampling functions in SPIR-V, as described in the Level-of-Detail Operation section.
- `anisotropyEnable` is `VK_TRUE` to enable anisotropic filtering, as described in the Texel Anisotropic Filtering section, or `VK_FALSE` otherwise.
- `maxAnisotropy` is the anisotropy value clamp used by the sampler when `anisotropyEnable` is `VK_TRUE`. If `anisotropyEnable` is `VK_FALSE`, `maxAnisotropy` is ignored.
- `compareEnable` is `VK_TRUE` to enable comparison against a reference value during lookups, or `VK_FALSE` otherwise.
• Note: Some implementations will default to shader state if this member does not match.

- `compareOp` is a `VkCompareOp` value specifying the comparison function to apply to fetched data before filtering as described in the Depth Compare Operation section.

- `minLod` and `maxLod` are the values used to clamp the computed LOD value, as described in the Level-of-Detail Operation section.

- `borderColor` is a `VkBorderColor` value specifying the predefined border color to use.

- `unnormalizedCoordinates` controls whether to use unnormalized or normalized texel coordinates to address texels of the image. When set to `VK_TRUE`, the range of the image coordinates used to lookup the texel is in the range of zero to the image dimensions for x, y and z. When set to `VK_FALSE` the range of image coordinates is zero to one.

When `unnormalizedCoordinates` is `VK_TRUE`, images the sampler is used with in the shader have the following requirements:

- The `viewType` must be either `VK_IMAGE_VIEW_TYPE_1D` or `VK_IMAGE_VIEW_TYPE_2D`.
- The image view must have a single layer and a single mip level.

When `unnormalizedCoordinates` is `VK_TRUE`, image built-in functions in the shader that use the sampler have the following requirements:

- The functions must not use projection.
- The functions must not use offsets.

---

### Mapping of OpenGL to Vulkan filter modes

- `magFilter` values of `VK_FILTER_NEAREST` and `VK_FILTER_LINEAR` directly correspond to `GL_NEAREST` and `GL_LINEAR` magnification filters. `minFilter` and `mipmapMode` combine to correspond to the similarly named OpenGL minification filter of `GL_minFilter_MIPMAP_mipmapMode` (e.g. `minFilter` of `VK_FILTER_LINEAR` and `mipmapMode` of `VK_SAMPLER_MIPMAP_MODE_NEAREST` correspond to `GL_LINEAR_MIPMAP_NEAREST`).

There are no Vulkan filter modes that directly correspond to OpenGL minification filters of `GL_LINEAR` or `GL_NEAREST`, but they can be emulated using `VK_SAMPLER_MIPMAP_MODE_NEAREST`, `minLod = 0`, and `maxLod = 0.25`, and using `minFilter = VK_FILTER_LINEAR` or `minFilter = VK_FILTER_NEAREST`, respectively.

Note that using a `maxLod` of zero would cause magnification to always be performed, and the `magFilter` to always be used. This is valid, just not an exact match for OpenGL behavior. Clamping the maximum LOD to 0.25 allows the λ value to be non-zero and minification to be performed, while still always rounding down to the base level. If the `minFilter` and `magFilter` are equal, then using a `maxLod` of zero also works.

The maximum number of sampler objects which can be simultaneously created on a device is implementation-dependent and specified by the `maxSamplerAllocationCount` member of the `VkPhysicalDeviceLimits` structure. If `maxSamplerAllocationCount` is exceeded, `vkCreateSampler` will return `VK_ERROR_TOO_MANY_OBJECTS`.
Since `VkSampler` is a non-dispatchable handle type, implementations may return the same handle for sampler state vectors that are identical. In such cases, all such objects would only count once against the `maxSamplerAllocationCount` limit.
Valid Usage

- The absolute value of \texttt{mipLodBias} must be less than or equal to \texttt{VkPhysicalDeviceLimits::maxSamplerLodBias}
- \texttt{maxLod} must be greater than or equal to \texttt{minLod}
- If the anisotropic sampling feature is not enabled, \texttt{anisotropyEnable} must be \texttt{VK_FALSE}
- If \texttt{anisotropyEnable} is \texttt{VK_TRUE}, \texttt{maxAnisotropy} must be between 1.0 and \texttt{VkPhysicalDeviceLimits::maxSamplerAnisotropy}, inclusive
- If \texttt{sampler Y'CbCr} conversion is enabled and the \texttt{sampler Y'CbCr} conversion's features do not support \texttt{VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_SEPARATE_RECONSTRUCTION_FILTER_BIT}, \texttt{minFilter} and \texttt{magFilter} must be equal to the sampler \texttt{Y'CbCr} conversion's \texttt{chromaFilter}
- If \texttt{unnormalizedCoordinates} is \texttt{VK_TRUE}, \texttt{mipmapMode} must be \texttt{VK_SAMPLER_MIPMAP_MODE_NEAREST}
- If \texttt{unnormalizedCoordinates} is \texttt{VK_TRUE}, \texttt{compareEnable} must be \texttt{VK_FALSE}
- If \texttt{unnormalizedCoordinates} is \texttt{VK_TRUE}, \texttt{unnormalizedCoordinates} must be \texttt{VK_FALSE}
- If \texttt{addressModeU}, \texttt{addressModeV} or \texttt{addressModeW} are \texttt{VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_BORDER}, \texttt{borderColor} must be a valid \texttt{VkBorderColor} value
- If \texttt{sampler Y'CbCr} conversion is enabled, \texttt{addressModeU}, \texttt{addressModeV}, and \texttt{addressModeW} must be \texttt{VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE}, \texttt{anisotropyEnable} must be \texttt{VK_FALSE}, and \texttt{unnormalizedCoordinates} must be \texttt{VK_FALSE}
- The sampler reduction mode must be set to \texttt{VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE} if \texttt{sampler Y'CbCr} conversion is enabled
- If the \texttt{VK_KHR_sampler_mirror_clamp_to_edge} extension is not enabled, \texttt{addressModeU}, \texttt{addressModeV} and \texttt{addressModeW} must not be \texttt{VK_SAMPLER_ADDRESS_MODE_MIRROR_CLAMP_TO_EDGE}
- If \texttt{compareEnable} is \texttt{VK_TRUE}, \texttt{compareOp} must be a valid \texttt{VkCompareOp} value
- If either \texttt{magFilter} or \texttt{minFilter} is \texttt{VK_FILTER_CUBIC_EXT}, \texttt{anisotropyEnable} must be \texttt{VK_FALSE}
- If \texttt{compareEnable} is \texttt{VK_TRUE}, the \texttt{reductionMode} member of \texttt{VkSamplerReductionModeCreateInfo} must be \texttt{VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE}
- If \texttt{flags} includes \texttt{VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT}, then \texttt{mipmapMode} must be \texttt{VK_SAMPLER_MIPMAP_MODE_NEAREST}
- If \texttt{flags} includes \texttt{VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT}, then \texttt{minLod} and \texttt{maxLod} must be zero
• If flags includes VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT, then addressModeU and addressModeV must each be either VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE or VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_BORDER

• If flags includes VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT, then anisotropyEnable must be VK_FALSE

• If flags includes VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT, then compareEnable must be VK_FALSE

• If flags includes VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT, then unnormalizedCoordinates must be VK_FALSE

• If borderColor is set to one of VK_BORDER_COLOR_FLOAT_CUSTOM_EXT or VK_BORDER_COLOR_INT_CUSTOM_EXT, then a VkSamplerCustomBorderColorCreateInfoEXT must be present in the pNext chain

• The maximum number of samplers with custom border colors which can be simultaneously created on a device is implementation-dependent and specified by the maxCustomBorderColorSamplers member of the VkPhysicalDeviceCustomBorderColorPropertiesEXT structure

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_SAMPLER_CREATE_INFO

• Each pNext member of any structure (including this one) in the pNext chain must be either NULL or a pointer to a valid instance of VkSamplerCustomBorderColorCreateInfoEXT, VkSamplerReductionModeCreateInfo, or VkSamplerYcbcrConversionInfo

• The sType value of each struct in the pNext chain must be unique

• flags must be a valid combination of VkSamplerCreateFlagBits values

• magFilter must be a valid VkFilter value

• minFilter must be a valid VkFilter value

•.mipmapMode must be a valid VkSamplerMipmapMode value

• addressModeU must be a valid VkSamplerAddressMode value

• addressModeV must be a valid VkSamplerAddressMode value

• addressModeW must be a valid VkSamplerAddressMode value

Bits which can be set in VkSamplerCreateInfo::flags, specifying additional parameters of a sampler, are:

typedef enum VkSamplerCreateFlagBits {
    VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT = 0x00000001,
    VK_SAMPLER_CREATE_SUBSAMPLED_COARSE_RECONSTRUCTION_BIT_EXT = 0x00000002,
} VkSamplerCreateFlagBits;

• VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT specifies that the sampler will read from an image
created with flags containing VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT.

- VK_SAMPLER_CREATE_SUBSAMPLED_COARSE_RECONSTRUCTION_BIT_EXT specifies that the implementation may use approximations when reconstructing a full color value for texture access from a subsampled image.

  Note
  The approximations used when VK_SAMPLER_CREATE_SUBSAMPLED_COARSE_RECONSTRUCTION_BIT_EXT is specified are implementation defined. Some implementations may interpolate between fragment density levels in a subsampled image. In that case, this bit may be used to decide whether the interpolation factors are calculated per fragment or at a coarser granularity.

```plaintext
typedef VkFlags VkSamplerCreateFlags;
```

VkSamplerCreateFlags is a bitmask type for setting a mask of zero or more VkSamplerCreateFlagBits.

The VkSamplerReductionModeCreateInfo structure is defined as:

```plaintext
typedef struct VkSamplerReductionModeCreateInfo {
    VkStructureType           sType;
    const void*               pNext;
    VkSamplerReductionMode    reductionMode;
} VkSamplerReductionModeCreateInfo;
```

or the equivalent

```plaintext
typedef VkSamplerReductionModeCreateInfo VkSamplerReductionModeCreateInfoEXT;
```

- sType is the type of this structure.
- pNext is NULL or a pointer to an extension-specific structure.
- reductionMode is a VkSamplerReductionMode value controlling how texture filtering combines texel values.

If the pNext chain of VkSamplerCreateInfo includes a VkSamplerReductionModeCreateInfo structure, then that structure includes a mode that controls how texture filtering combines texel values.

If this structure is not present, reductionMode is considered to be VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE.
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_SAMPLER_REDUCTION_MODE_CREATE_INFO`
- `reductionMode` must be a valid `VkSamplerReductionMode` value

Reduction modes are specified by `VkSamplerReductionMode`, which takes values:

```c
typedef enum VkSamplerReductionMode {
    VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE = 0,
    VK_SAMPLER_REDUCTION_MODE_MIN = 1,
    VK_SAMPLER_REDUCTION_MODE_MAX = 2,
    VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE_EXT = VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE,
    VK_SAMPLER_REDUCTION_MODE_MIN_EXT = VK_SAMPLER_REDUCTION_MODE_MIN,
    VK_SAMPLER_REDUCTION_MODE_MAX_EXT = VK_SAMPLER_REDUCTION_MODE_MAX,
} VkSamplerReductionMode;
```

or the equivalent

```c
typedef VkSamplerReductionMode VkSamplerReductionModeEXT;
```

- `VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE` specifies that texel values are combined by computing a weighted average of values in the footprint, using weights as specified in the image operations chapter.
- `VK_SAMPLER_REDUCTION_MODE_MIN` specifies that texel values are combined by taking the component-wise minimum of values in the footprint with non-zero weights.
- `VK_SAMPLER_REDUCTION_MODE_MAX` specifies that texel values are combined by taking the component-wise maximum of values in the footprint with non-zero weights.

Possible values of the `VkSamplerCreateInfo::magFilter` and `minFilter` parameters, specifying filters used for texture lookups, are:

```c
typedef enum VkFilter {
    VK_FILTER_NEAREST = 0,
    VK_FILTER_LINEAR = 1,
    VK_FILTER_CUBIC_IMG = 1000015000,
    VK_FILTER_CUBIC_EXT = VK_FILTER_CUBIC_IMG,
} VkFilter;
```

- `VK_FILTER_NEAREST` specifies nearest filtering.
- `VK_FILTER_LINEAR` specifies linear filtering.
- `VK_FILTER_CUBIC_EXT` specifies cubic filtering.
These filters are described in detail in _Texel Filtering_.

Possible values of the `VkSamplerCreateInfo::mipmapMode`, specifying the mipmap mode used for texture lookups, are:

```
typedef enum VkSamplerMipmapMode {
    VK_SAMPLER_MIPMAP_MODE_NEAREST = 0,
    VK_SAMPLER_MIPMAP_MODE_LINEAR = 1,
} VkSamplerMipmapMode;
```

- `VK_SAMPLER_MIPMAP_MODE_NEAREST` specifies nearest filtering.
- `VK_SAMPLER_MIPMAP_MODE_LINEAR` specifies linear filtering.

These modes are described in detail in _Texel Filtering_.

Possible values of the `VkSamplerCreateInfo::addressMode*` parameters, specifying the behavior of sampling with coordinates outside the range \([0,1]\) for the respective \(u, v,\) or \(w\) coordinate as defined in the _Wrapping Operation_ section, are:

```
typedef enum VkSamplerAddressMode {
    VK_SAMPLER_ADDRESS_MODE_REPEAT = 0,
    VK_SAMPLER_ADDRESS_MODE_MIRRORED_REPEAT = 1,
    VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE = 2,
    VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_BORDER = 3,
    VK_SAMPLER_ADDRESS_MODE_MIRROR_CLAMP_TO_EDGE = 4,
    VK_SAMPLER_ADDRESS_MODE_MIRROR_CLAMP_TO_EDGE_KHR = VK_SAMPLER_ADDRESS_MODE_MIRROR_CLAMP_TO_EDGE,
} VkSamplerAddressMode;
```

- `VK_SAMPLER_ADDRESS_MODE_REPEAT` specifies that the repeat wrap mode will be used.
- `VK_SAMPLER_ADDRESS_MODE_MIRRORED_REPEAT` specifies that the mirrored repeat wrap mode will be used.
- `VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE` specifies that the clamp to edge wrap mode will be used.
- `VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_BORDER` specifies that the clamp to border wrap mode will be used.
- `VK_SAMPLER_ADDRESS_MODE_MIRROR_CLAMP_TO_EDGE` specifies that the mirror clamp to edge wrap mode will be used. This is only valid if the `VK_KHR_sampler_mirror_clamp_to_edge` extension is enabled.

Possible values of `VkSamplerCreateInfo::borderColor`, specifying the border color used for texture lookups, are:
typedef enum VkBorderColor {
    VK_BORDER_COLOR_FLOAT_TRANSPARENT_BLACK = 0,
    VK_BORDER_COLOR_INT_TRANSPARENT_BLACK = 1,
    VK_BORDER_COLOR_FLOAT_OPAQUE_BLACK = 2,
    VK_BORDER_COLOR_INT_OPAQUE_BLACK = 3,
    VK_BORDER_COLOR_FLOAT_OPAQUE_WHITE = 4,
    VK_BORDER_COLOR_INT_OPAQUE_WHITE = 5,
    VK_BORDER_COLOR_FLOAT_CUSTOM_EXT = 1000287003,
    VK_BORDER_COLOR_INT_CUSTOM_EXT = 1000287004,
} VkBorderColor;

- `VK_BORDER_COLOR_FLOAT_TRANSPARENT_BLACK` specifies a transparent, floating-point format, black color.
- `VK_BORDER_COLOR_INT_TRANSPARENT_BLACK` specifies a transparent, integer format, black color.
- `VK_BORDER_COLOR_FLOAT_OPAQUE_BLACK` specifies an opaque, floating-point format, black color.
- `VK_BORDER_COLOR_INT_OPAQUE_BLACK` specifies an opaque, integer format, black color.
- `VK_BORDER_COLOR_FLOAT_OPAQUE_WHITE` specifies an opaque, floating-point format, white color.
- `VK_BORDER_COLOR_INT_OPAQUE_WHITE` specifies an opaque, integer format, white color.
- `VK_BORDER_COLOR_FLOAT_CUSTOM_EXT` indicates that a `VkSamplerCustomBorderColorCreateInfoEXT` structure is present in the `VkSamplerCreateInfo::pNext` chain which contains the color data in floating-point format.
- `VK_BORDER_COLOR_INT_CUSTOM_EXT` indicates that a `VkSamplerCustomBorderColorCreateInfoEXT` structure is present in the `VkSamplerCreateInfo::pNext` chain which contains the color data in integer format.

These colors are described in detail in Texel Replacement.

To destroy a sampler, call:

```c
void vkDestroySampler(
    VkDevice device,       
    VkSampler sampler,     
    const VkAllocationCallbacks* pAllocator);
```

- `device` is the logical device that destroys the sampler.
- `sampler` is the sampler to destroy.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
Valid Usage

- All submitted commands that refer to sampler must have completed execution
- If VkAllocationCallbacks were provided when sampler was created, a compatible set of callbacks must be provided here
- If no VkAllocationCallbacks were provided when sampler was created, pAllocator must be NULL

Valid Usage (Implicit)

- device must be a valid VkDevice handle
- If sampler is not VK_NULL_HANDLE, sampler must be a valid VkSampler handle
- If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure
- If sampler is a valid handle, it must have been created, allocated, or retrieved from device

Host Synchronization

- Host access to sampler must be externally synchronized

12.1. Sampler Y'CbCr conversion

To create a sampler with Y'CbCr conversion enabled, add a VkSamplerYcbcrConversionInfo structure to the pNext chain of the VkSamplerCreateInfo structure. To create a sampler Y'CbCr conversion, the samplerYcbcrConversion feature must be enabled. Conversion must be fixed at pipeline creation time, through use of a combined image sampler with an immutable sampler in VkDescriptorSetLayoutBinding.

A VkSamplerYcbcrConversionInfo must be provided for samplers to be used with image views that access VK_IMAGE_ASPECT_COLOR_BIT if the format appears in Formats requiring sampler Y'CbCr conversion for VK_IMAGE_ASPECT_COLOR_BIT image views, or if the image view has an external format.

The VkSamplerYcbcrConversionInfo structure is defined as:

typedef struct VkSamplerYcbcrConversionInfo {
    VkStructureType          sType;
    const void*              pNext;
    VkSamplerYcbcrConversion conversion;
} VkSamplerYcbcrConversionInfo;

or the equivalent
typedef VkSamplerYcbcrConversionInfo VkSamplerYcbcrConversionInfoKHR;

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `conversion` is a `VkSamplerYcbcrConversion` handle created with `vkCreateSamplerYcbcrConversion`.

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_SAMPLER_YCBCR_CONVERSION_INFO`
- `conversion` must be a valid `VkSamplerYcbcrConversion` handle

A sampler $Y'C_bC_R$ conversion is an opaque representation of a device-specific sampler $Y'C_bC_R$ conversion description, represented as a `VkSamplerYcbcrConversion` handle:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkSamplerYcbcrConversion)
```

or the equivalent

```c
typedef VkSamplerYcbcrConversion VkSamplerYcbcrConversionKHR;
```

To create a `VkSamplerYcbcrConversion`, call:

```c
VkResult vkCreateSamplerYcbcrConversionKHR(
    VkDevice                                    device,
    const VkSamplerYcbcrConversionCreateInfo*   pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkSamplerYcbcrConversion*                   pYcbcrConversion);
```

- `device` is the logical device that creates the sampler $Y'C_bC_R$ conversion.
- `pCreateInfo` is a pointer to a `VkSamplerYcbcrConversionCreateInfo` structure specifying the requested sampler $Y'C_bC_R$ conversion.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.
- `pYcbcrConversion` is a pointer to a `VkSamplerYcbcrConversion` handle in which the resulting sampler $Y'C_bC_R$ conversion is returned.

The interpretation of the configured sampler $Y'C_bC_R$ conversion is described in more detail in the description of sampler $Y'C_bC_R$ conversion in the Image Operations chapter.
Valid Usage

• The sampler Y’C₆C₆ conversion feature must be enabled

Valid Usage (Implicit)

• device must be a valid VkDevice handle
• pCreateInfo must be a valid pointer to a valid VkSamplerYcbcrConversionCreateInfo structure
• If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure
• pYcbcrConversion must be a valid pointer to a VkSamplerYcbcrConversion handle

Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

The VkSamplerYcbcrConversionCreateInfo structure is defined as:

```c
typedef struct VkSamplerYcbcrConversionCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkFormat format;
    VkSamplerYcbcrModelConversion ycbcrModel;
    VkSamplerYcbcrRange ycbcrRange;
    VkComponentMapping components;
    VkChromaLocation xChromaOffset;
    VkChromaLocation yChromaOffset;
    VkFilter chromaFilter;
    VkBool32 forceExplicitReconstruction;
} VkSamplerYcbcrConversionCreateInfo;
```

or the equivalent

```c
typedef VkSamplerYcbcrConversionCreateInfo VkSamplerYcbcrConversionCreateInfoKHR;
```

• sType is the type of this structure.
• **pNext** is **NULL** or a pointer to an extension-specific structure.

• **format** is the format of the image from which color information will be retrieved.

• **ycbcrModel** describes the color matrix for conversion between color models.

• **ycbcrRange** describes whether the encoded values have headroom and foot room, or whether the encoding uses the full numerical range.

• **components** applies a swizzle based on **VkComponentSwizzle** enums prior to range expansion and color model conversion.

• **xChromaOffset** describes the sample location associated with downsampled chroma channels in the x dimension. **xChromaOffset** has no effect for formats in which chroma channels are the same resolution as the luma channel.

• **yChromaOffset** describes the sample location associated with downsampled chroma channels in the y dimension. **yChromaOffset** has no effect for formats in which the chroma channels are not downsampled vertically.

• **chromaFilter** is the filter for chroma reconstruction.

• **forceExplicitReconstruction** can be used to ensure that reconstruction is done explicitly, if supported.

---

**Note**

Setting **forceExplicitReconstruction** to **VK_TRUE** may have a performance penalty on implementations where explicit reconstruction is not the default mode of operation.

If **format** supports **VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_CHROMA_RECONSTRUCTION_EXPLICIT_BIT** the **forceExplicitReconstruction** value behaves as if it was set to **VK_TRUE**.

---

If the **pNext** chain includes a **VkExternalFormatANDROID** structure with non-zero **externalFormat** member, the sampler Y’C’bC’r conversion object represents an external format conversion, and **format** must be **VK_FORMAT_UNDEFINED**. Such conversions must only be used to sample image views with a matching external format. When creating an external format conversion, the value of **components** is ignored.
Valid Usage

• If an external format conversion is being created, **format must be** VK_FORMAT_UNDEFINED, otherwise it **must not be** VK_FORMAT_UNDEFINED.

• The sampler $Y'CbCr$ conversion's features **must** support
  
  - VK_FORMAT_FEATURE_MIDPOINT_CHROMA_SAMPLES_BIT
  - VK_FORMAT_FEATURE_COSITED_CHROMA_SAMPLES_BIT

• If the sampler $Y'CbCr$ conversion's features do not support
  
  - VK_FORMAT_FEATURE_COSITED_CHROMA_SAMPLES_BIT, $xChromaOffset$ and $yChromaOffset$ **must not be** VK_CHROMA_LOCATION_COSITED_EVEN

• If the sampler $Y'CbCr$ conversion's features do not support
  
  - VK_FORMAT_FEATURE_MIDPOINT_CHROMA_SAMPLES_BIT, $xChromaOffset$ and $yChromaOffset$ **must not be** VK_CHROMA_LOCATION_MIDPOINT

• If the format has a _422 or _420 suffix, then $\text{components.g}$ **must be** VK_COMPONENT_SWIZZLE_IDENTITY

• If the format has a _422 or _420 suffix, then $\text{components.a}$ **must be** VK_COMPONENT_SWIZZLE_IDENTITY, VK_COMPONENT_SWIZZLE_ONE, or VK_COMPONENT_SWIZZLE_ZERO

• If the format has a _422 or _420 suffix, then $\text{components.r}$ **must be** VK_COMPONENT_SWIZZLE_IDENTITY or VK_COMPONENT_SWIZZLE_B

• If the format has a _422 or _420 suffix, then $\text{components.b}$ **must be** VK_COMPONENT_SWIZZLE_IDENTITY or VK_COMPONENT_SWIZZLE_R

• If the format has a _422 or _420 suffix, and if either $\text{components.r}$ or $\text{components.b}$ is VK_COMPONENT_SWIZZLE_IDENTITY, both values **must be** VK_COMPONENT_SWIZZLE_IDENTITY

• If $\text{ycbcrModel}$ is not VK_SAMPLER_YCBCR_MODEL_CONVERSION_RGB_IDENTITY, then $\text{components.r}$, $\text{components.g}$, and $\text{components.b}$ **must correspond to channels of the format**; that is, $\text{components.r}$, $\text{components.g}$, and $\text{components.b}$ **must not be** VK_COMPONENT_SWIZZLE_ZERO or VK_COMPONENT_SWIZZLE_ONE, and **must not correspond to a channel which contains zero or one as a consequence of conversion to RGBA**

• If $\text{ycbcrRange}$ is VK_SAMPLER_YCBCR_RANGE_ITU_NARROW then the R, G and B channels obtained by applying the component swizzle to **format** each have a bit-depth greater than or equal to 8

• If the sampler $Y'CbCr$ conversion's features do not support
  
  - VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_CHROMA_RECONSTRUCTION_EXPLICIT_FORCEABLE_BIT, $\text{forceExplicitReconstruction}$ **must be** VK_FALSE

• If the sampler $Y'CbCr$ conversion's features do not support
  
  - VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_LINEAR_FILTER_BIT, $\text{chromaFilter}$ **must not be** VK_FILTER_LINEAR
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_SAMPLER_YCBCR_CONVERSION_CREATE_INFO`
- **pNext** must be `NULL` or a pointer to a valid instance of `VkExternalFormatANDROID`
- The **sType** value of each struct in the **pNext** chain must be unique
- **format** must be a valid `VkFormat` value
- **ycbcrModel** must be a valid `VkSamplerYcbcrModelConversion` value
- **ycbcrRange** must be a valid `VkSamplerYcbcrRange` value
- **components** must be a valid `VkComponentMapping` structure
- **xChromaOffset** must be a valid `VkChromaLocation` value
- **yChromaOffset** must be a valid `VkChromaLocation` value
- **chromaFilter** must be a valid `VkFilter` value

If **chromaFilter** is `VK_FILTER_NEAREST`, chroma samples are reconstructed to luma channel resolution using nearest-neighbour sampling. Otherwise, chroma samples are reconstructed using interpolation. More details can be found in the description of sampler Y’C_bC_r conversion in the Image Operations chapter.

`VkSamplerYcbcrModelConversion` defines the conversion from the source color model to the shader color model. Possible values are:

```c
typedef enum VkSamplerYcbcrModelConversion {
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_RGB_IDENTITY = 0,
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_IDENTITY = 1,
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_709 = 2,
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_601 = 3,
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_2020 = 4,
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_RGB_IDENTITY_KHR =
        VK_SAMPLER_YCBCR_MODEL_CONVERSION_RGB_IDENTITY,
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_IDENTITY_KHR =
        VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_IDENTITY,
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_709_KHR =
        VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_709,
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_601_KHR =
        VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_601,
    VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_2020_KHR =
        VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_2020,
} VkSamplerYcbcrModelConversion;
```

or the equivalent

```c
typedef VkSamplerYcbcrModelConversion VkSamplerYcbcrModelConversionKHR;
```
• **VK_SAMPLER_YCBCR_MODEL_CONVERSION_RGB_IDENTITY** specifies that the input values to the conversion are unmodified.

• **VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_IDENTITY** specifies no model conversion but the inputs are range expanded as for Y’C_bC_r.

• **VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_709** specifies the color model conversion from Y’C_bC_r to R’G’B’ defined in BT.709 and described in the “BT.709 Y’C_bC_r conversion” section of the Khronos Data Format Specification.

• **VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_601** specifies the color model conversion from Y’C_bC_r to R’G’B’ defined in BT.601 and described in the “BT.601 Y’C_bC_r conversion” section of the Khronos Data Format Specification.

• **VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_2020** specifies the color model conversion from Y’C_bC_r to R’G’B’ defined in BT.2020 and described in the “BT.2020 Y’C_bC_r conversion” section of the Khronos Data Format Specification.

In the **VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_*** color models, for the input to the sampler Y’C_bC_r range expansion and model conversion:

• the Y (Y’ luma) channel corresponds to the G channel of an RGB image.

• the CB (C_b or “U” blue color difference) channel corresponds to the B channel of an RGB image.

• the CR (C_r or “V” red color difference) channel corresponds to the R channel of an RGB image.

• the alpha channel, if present, is not modified by color model conversion.

These rules reflect the mapping of channels after the channel swizzle operation (controlled by VkSamplerYcbcrConversionCreateInfo::components).

**Note**
For example, an “YUVA” 32-bit format comprising four 8-bit channels can be implemented as VK_FORMAT_R8G8B8A8_UNORM with a component mapping:

- components.a = VK_COMPONENT_SWIZZLE_IDENTITY
- components.r = VK_COMPONENT_SWIZZLE_B
- components.g = VK_COMPONENT_SWIZZLE_R
- components.b = VK_COMPONENT_SWIZZLE_G

The **VkSamplerYcbcrRange** enum describes whether color channels are encoded using the full range of numerical values or whether values are reserved for headroom and foot room. **VkSamplerYcbcrRange** is defined as:

```c
typedef enum VkSamplerYcbcrRange {
    VK_SAMPLER_YCBCR_RANGE_ITU_FULL = 0,
    VK_SAMPLER_YCBCR_RANGE_ITU_NARROW = 1,
}
```
or the equivalent

```c
typedef VkSamplerYcbcrRange VkSamplerYcbcrRangeKHR;
```

- **VK_SAMPLER_YCBCR_RANGE_ITU_FULL** specifies that the full range of the encoded values are valid and interpreted according to the ITU “full range” quantization rules.
- **VK_SAMPLER_YCBCR_RANGE_ITU_NARROW** specifies that headroom and foot room are reserved in the numerical range of encoded values, and the remaining values are expanded according to the ITU “narrow range” quantization rules.

The formulae for these conversions is described in the Sampler Y’C₆₅₆ Range Expansion section of the Image Operations chapter.

No range modification takes place if ycbcrModel is **VK_SAMPLER_YCBCR_MODEL_CONVERSION_RGB_IDENTITY**; the ycbcrRange field of *VkSamplerYcbcrConversionCreateInfo* is ignored in this case.

The **VkChromaLocation** enum defines the location of downsampled chroma channel samples relative to the luma samples, and is defined as:

```c
typedef enum VkChromaLocation {
    VK_CHROMA_LOCATION_COSITED_EVEN = 0,
    VK_CHROMA_LOCATION_MIDPOINT = 1,
    VK_CHROMA_LOCATION_COSITED_EVEN_KHR = VK_CHROMA_LOCATION_COSITED_EVEN,
    VK_CHROMA_LOCATION_MIDPOINT_KHR = VK_CHROMA_LOCATION_MIDPOINT,
} VkChromaLocation;
```

or the equivalent

```c
typedef VkChromaLocation VkChromaLocationKHR;
```

- **VK_CHROMA_LOCATION_COSITED_EVEN** specifies that downsampled chroma samples are aligned with luma samples with even coordinates.
- **VK_CHROMA_LOCATION_MIDPOINT** specifies that downsampled chroma samples are located half way between each even luma sample and the nearest higher odd luma sample.

To destroy a sampler Y’C₆₅₆ conversion, call:

```c
void vkDestroySamplerYcbcrConversionKHR(
    VkDevice                                    device,
    VkSamplerYcbcrConversion                    ycbcrConversion,
    const VkAllocationCallbacks*                pAllocator);
```

- **device** is the logical device that destroys the Y’C₆₅₆ conversion.
- **ycbcrConversion** is the conversion to destroy.
• pAllocator controls host memory allocation as described in the Memory Allocation chapter.

Valid Usage (Implicit)

• device must be a valid VkDevice handle

• If ycbcrConversion is not VK_NULL_HANDLE, ycbcrConversion must be a valid VkSamplerYcbcrConversion handle

• If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure

• If ycbcrConversion is a valid handle, it must have been created, allocated, or retrieved from device

Host Synchronization

• Host access to ycbcrConversion must be externally synchronized

12.1.1. Sampler Ycbcr Conversion Format Features

Valid uses of a VkSamplerYcbcrConversion may depend on format features, defined below. Such constraints are documented in the affected valid usage statement.

• The format features of a VkSamplerYcbcrConversion include any feature that is supported for VkSamplerYcbcrConversionCreateInfo::format in one or more of VK_IMAGE_TILING_OPTIMAL or VK_IMAGE_TILING_DRM_FORMAT_MODIFIER_EXT or VK_IMAGE_TILING_LINEAR if format is not VK_FORMAT_UNDEFINED

• If VkSamplerYcbcrConversionCreateInfo::format is VK_FORMAT_UNDEFINED and a valid external format conversion is being created, then the format feature of a VkSamplerYcbcrConversion include only features supported in VkAndroidHardwareBufferFormatPropertiesANDROID::formatFeatures

In addition to the predefined border color values, applications can provide a custom border color value by including the VkSamplerCustomBorderColorCreateInfoEXT structure in the VkSamplerCreateInfo::pNext chain.

The VkSamplerCustomBorderColorCreateInfoEXT structure is defined as:

```c
typedef struct VkSamplerCustomBorderColorCreateInfoEXT {
    VkStructureType           sType;
    const void*               pNext;
    VkClearColorValue         customBorderColor;
    VkFormat                  format;
} VkSamplerCustomBorderColorCreateInfoEXT;
```

• sType is the type of this structure.
• `pNext` is `NULL` or a pointer to an extension-specific structure.

• `customBorderColor` is a `VkClearColorValue` representing the desired custom sampler border color.

• `format` is a `VkFormat` representing the format of the sampled image view(s). This field may be `VK_FORMAT_UNDEFINED` if the `customBorderColorWithoutFormat` feature is enabled.

## Valid Usage

- If provided `format` is not `VK_FORMAT_UNDEFINED` then the `VkSamplerCreateInfo::borderColor` type must match the sampled type of the provided `format`, as shown in the `SPIR-V Sampled Type` column of the Interpretation of Numeric Format table.

- If the `customBorderColorWithoutFormat` feature is not enabled then `format` must not be `VK_FORMAT_UNDEFINED`.

- If the sampler is used to sample an image view of `VK_FORMAT_B4G4R4A4_UNORM_PACK16` format then `format` must not be `VK_FORMAT_UNDEFINED`.

## Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_SAMPLER_CUSTOM_BORDER_COLOR_CREATE_INFO_EXT`.

- `format` must be a valid `VkFormat` value.
Chapter 13. Resource Descriptors

A descriptor is an opaque data structure representing a shader resource such as a buffer, buffer view, image view, sampler, or combined image sampler. Descriptors are organised into descriptor sets, which are bound during command recording for use in subsequent draw commands. The arrangement of content in each descriptor set is determined by a descriptor set layout, which determines what descriptors can be stored within it. The sequence of descriptor set layouts that can be used by a pipeline is specified in a pipeline layout. Each pipeline object can use up to maxBoundDescriptorSets (see Limits) descriptor sets.

Shaders access resources via variables decorated with a descriptor set and binding number that link them to a descriptor in a descriptor set. The shader interface mapping to bound descriptor sets is described in the Shader Resource Interface section.

Shaders can also access buffers without going through descriptors by using Physical Storage Buffer Access to access them through 64-bit addresses.

13.1. Descriptor Types

There are a number of different types of descriptor supported by Vulkan, corresponding to different resources or usage. The following sections describe the API definitions of each descriptor type. The mapping of each type to SPIR-V is listed in the Shader Resource and Descriptor Type Correspondence and Shader Resource and Storage Class Correspondence tables in the Shader Interfaces chapter.

13.1.1. Storage Image

A storage image (VK_DESCRIPTOR_TYPE_STORAGE_IMAGE) is a descriptor type associated with an image resource via an image view that load, store, and atomic operations can be performed on.

Storage image loads are supported in all shader stages for image views whose format features contain VK_FORMAT_FEATURE_STORAGE_IMAGE_BIT.

Stores to storage images are supported in compute shaders for image views whose format features contain VK_FORMAT_FEATURE_STORAGE_IMAGE_BIT.

Atomic operations on storage images are supported in compute shaders for image views whose format features contain VK_FORMAT_FEATURE_STORAGE_IMAGE_ATOMIC_BIT.

When the fragmentStoresAndAtomics feature is enabled, stores and atomic operations are also supported for storage images in fragment shaders with the same set of image formats as supported in compute shaders. When the vertexPipelineStoresAndAtomics feature is enabled, stores and atomic operations are also supported in vertex, tessellation, and geometry shaders with the same set of image formats as supported in compute shaders.

The image subresources for a storage image must be in the VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR or VK_IMAGE_LAYOUT_GENERAL layout in order to access its data in a shader.
13.1.2. Sampler

A sampler descriptor (VK_DESCRIPTOR_TYPE_SAMPLER) is a descriptor type associated with a sampler object, used to control the behavior of sampling operations performed on a sampled image.

13.1.3. Sampled Image

A sampled image (VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE) is a descriptor type associated with an image resource via an image view that sampling operations can be performed on.

Shaders combine a sampled image variable and a sampler variable to perform sampling operations.

Sampled images are supported in all shader stages for image views whose format features contain VK_FORMAT_FEATURE_SAMPLED_IMAGE_BIT.

The image subresources for a sampled image must be in the VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR, VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL, VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL, or VK_IMAGE_LAYOUT_GENERAL layout in order to access its data in a shader.

13.1.4. Combined Image Sampler

A combined image sampler (VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER) is a single descriptor type associated with both a sampler and an image resource, combining both a sampler and sampled image descriptor into a single descriptor.

If the descriptor refers to a sampler that performs Y′CbCr conversion or samples a subsampled image, the sampler must only be used to sample the image in the same descriptor. Otherwise, the sampler and image in this type of descriptor can be used freely with any other samplers and images.

The image subresources for a combined image sampler must be in the VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR, VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL, VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL, VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL, or VK_IMAGE_LAYOUT_GENERAL layout in order to access its data in a shader.

Note

On some implementations, it may be more efficient to sample from an image using a combination of sampler and sampled image that are stored together in the descriptor set in a combined descriptor.

13.1.5. Uniform Texel Buffer

A uniform texel buffer (VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER) is a descriptor type associated with a buffer resource via a buffer view that formatted load operations can be performed on.
Uniform texel buffers define a tightly-packed 1-dimensional linear array of texels, with texels going through format conversion when read in a shader in the same way as they are for an image.

Load operations from uniform texel buffers are supported in all shader stages for image formats which report support for the `VK_FORMAT_FEATURE_UNIFORM_TEXEL_BUFFER_BIT` feature bit via `vkGetPhysicalDeviceFormatProperties` in `VkFormatProperties::bufferFeatures`.

### 13.1.6. Storage Texel Buffer

A storage texel buffer (`VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER`) is a descriptor type associated with a buffer resource via a buffer view that formatted load, store, and atomic operations can be performed on.

Storage texel buffers define a tightly-packed 1-dimensional linear array of texels, with texels going through format conversion when read in a shader in the same way as they are for an image. Unlike uniform texel buffers, these buffers can also be written to in the same way as for storage images.

Storage texel buffer loads are supported in all shader stages for texel buffer formats which report support for the `VK_FORMAT_FEATURE_STORAGE_TEXEL_BUFFER_BIT` feature bit via `vkGetPhysicalDeviceFormatProperties` in `VkFormatProperties::bufferFeatures`.

Stores to storage texel buffers are supported in compute shaders for texel buffer formats which report support for the `VK_FORMAT_FEATURE_STORAGE_TEXEL_BUFFER_BIT` feature via `vkGetPhysicalDeviceFormatProperties` in `VkFormatProperties::bufferFeatures`.

Atomic operations on storage texel buffers are supported in compute shaders for texel buffer formats which report support for the `VK_FORMAT_FEATURE_STORAGE_TEXEL_BUFFER_ATOMIC_BIT` feature via `vkGetPhysicalDeviceFormatProperties` in `VkFormatProperties::bufferFeatures`.

When the `fragmentStoresAndAtomics` feature is enabled, stores and atomic operations are also supported for storage texel buffers in fragment shaders with the same set of texel buffer formats as supported in compute shaders. When the `vertexPipelineStoresAndAtomics` feature is enabled, stores and atomic operations are also supported in vertex, tessellation, and geometry shaders with the same set of texel buffer formats as supported in compute shaders.

### 13.1.7. Storage Buffer

A storage buffer (`VK_DESCRIPTOR_TYPE_STORAGE_BUFFER`) is a descriptor type associated with a buffer resource directly, described in a shader as a structure with various members that load, store, and atomic operations can be performed on.

Note

Atomic operations can only be performed on members of certain types as defined in the SPIR-V environment appendix.

### 13.1.8. Uniform Buffer

A uniform buffer (`VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER`) is a descriptor type associated with a buffer resource directly, described in a shader as a structure with various members that load operations
can be performed on.

13.1.9. Dynamic Uniform Buffer

A dynamic uniform buffer (**VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC**) is almost identical to a uniform buffer, and differs only in how the offset into the buffer is specified. The base offset calculated by the **VkDescriptorBufferInfo** when initially updating the descriptor set is added to a dynamic offset when binding the descriptor set.

13.1.10. Dynamic Storage Buffer

A dynamic storage buffer (**VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC**) is almost identical to a storage buffer, and differs only in how the offset into the buffer is specified. The base offset calculated by the **VkDescriptorBufferInfo** when initially updating the descriptor set is added to a dynamic offset when binding the descriptor set.

13.1.11. Inline Uniform Block

An inline uniform block (**VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT**) is almost identical to a uniform buffer, and differs only in taking its storage directly from the encompassing descriptor set instead of being backed by buffer memory. It is typically used to access a small set of constant data that does not require the additional flexibility provided by the indirection enabled when using a uniform buffer where the descriptor and the referenced buffer memory are decoupled. Compared to push constants, they allow reusing the same set of constant data across multiple disjoint sets of draw and dispatch commands.

Inline uniform block descriptors cannot be aggregated into arrays. Instead, the array size specified for an inline uniform block descriptor binding specifies the binding’s capacity in bytes.

13.1.12. Input Attachment

An input attachment (**VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT**) is a descriptor type associated with an image resource via an image view that can be used for framebuffer local load operations in fragment shaders.

All image formats that are supported for color attachments (**VK_FORMAT_FEATURE_COLOR_ATTACHMENT_BIT**) or depth/stencil attachments (**VK_FORMAT_FEATURE_DEPTH_STENCIL_ATTACHMENT_BIT**) for a given image tiling mode are also supported for input attachments.

The image subresources for an input attachment must be in the **VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR**, **VK_IMAGE_LAYOUT_DEPTH_READ_ONLY_STENCIL_ATTACHMENT_OPTIMAL**, **VK_IMAGE_LAYOUT_DEPTH_ATTACHMENT_STENCIL_READ_ONLY_OPTIMAL**, **VK_IMAGE_LAYOUT_DEPTH_STENCIL_READ_ONLY_OPTIMAL**, or **VK_IMAGE_LAYOUT_SHADER_READ_ONLY_OPTIMAL** layout in order to access its data in a shader.

13.1.13. Acceleration Structure

An acceleration structure (**VK_DESCRIPTOR_TYPE_ACCELERATION_STRUCTURE_KHR**) is a descriptor type that
is used to retrieve scene geometry from within shaders bound to ray tracing pipelines. Shaders have read-only access to the memory.

### 13.2. Descriptor Sets

Descriptors are grouped together into descriptor set objects. A descriptor set object is an opaque object containing storage for a set of descriptors, where the types and number of descriptors is defined by a descriptor set layout. The layout object **may** be used to define the association of each descriptor binding with memory or other implementation resources. The layout is used both for determining the resources that need to be associated with the descriptor set, and determining the interface between shader stages and shader resources.

#### 13.2.1. Descriptor Set Layout

A descriptor set layout object is defined by an array of zero or more descriptor bindings. Each individual descriptor binding is specified by a descriptor type, a count (array size) of the number of descriptors in the binding, a set of shader stages that **can** access the binding, and (if using immutable samplers) an array of sampler descriptors.

Descriptor set layout objects are represented by `VkDescriptorSetLayout` handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkDescriptorSetLayout)
```

To create descriptor set layout objects, call:

```c
VkResult vkCreateDescriptorSetLayout(  
    VkDevice                                 device,  
    const VkDescriptorSetLayoutCreateInfo* pCreateInfo,  
    const VkAllocationCallbacks*           pAllocator,  
    VkDescriptorSetLayout*                 pSetLayout);
```

- **device** is the logical device that creates the descriptor set layout.
- **pCreateInfo** is a pointer to a `VkDescriptorSetLayoutCreateInfo` structure specifying the state of the descriptor set layout object.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pSetLayout** is a pointer to a `VkDescriptorSetLayout` handle in which the resulting descriptor set layout object is returned.
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle
- **pCreateInfo** must be a valid pointer to a valid `VkDescriptorSetLayoutCreateInfo` structure
- If **pAllocator** is not **NULL**, **pAllocator** must be a valid pointer to a valid `VkAllocationCallbacks` structure
- **pSetLayout** must be a valid pointer to a `VkDescriptorSetLayout` handle

Return Codes

**Success**
- **VK_SUCCESS**

**Failure**
- **VK_ERROR_OUT_OF_HOST_MEMORY**
- **VK_ERROR_OUT_OF_DEVICE_MEMORY**

Information about the descriptor set layout is passed in a `VkDescriptorSetLayoutCreateInfo` structure:

```c
typedef struct VkDescriptorSetLayoutCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkDescriptorSetLayoutCreateFlags flags;
    uint32_t bindingCount;
    const VkDescriptorSetLayoutBinding* pBindings;
} VkDescriptorSetLayoutCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **flags** is a bitmask of `VkDescriptorSetLayoutCreateFlagBits` specifying options for descriptor set layout creation.
- **bindingCount** is the number of elements in **pBindings**.
- **pBindings** is a pointer to an array of `VkDescriptorSetLayoutBinding` structures.
Valid Usage

• The VkDescriptorSetLayoutBinding::binding members of the elements of the pBindings array must each have different values

• If flags contains VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR, then all elements of pBindings must not have a descriptorType of VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC or VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC

• If flags contains VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR, then all elements of pBindings must not have a descriptorType of VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT

• If flags contains VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR, then the total number of elements of all bindings must be less than or equal to VkPhysicalDevicePushDescriptorPropertiesKHR::maxPushDescriptors

• If any binding has the VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT bit set, flags must include VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT

• If any binding has the VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT bit set, then all bindings must not have descriptorType of VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC or VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_DESCRIPTOR_SET_LAYOUT_CREATE_INFO

• pNext must be NULL or a pointer to a valid instance of VkDescriptorSetLayoutBindingFlagsCreateInfo

• The sType value of each struct in the pNext chain must be unique

• flags must be a valid combination of VkDescriptorSetLayoutCreateFlagBits values

• If bindingCount is not 0, pBindings must be a valid pointer to an array of bindingCount valid VkDescriptorSetLayoutBinding structures

Bits which can be set in VkDescriptorSetLayoutCreateInfo::flags to specify options for descriptor set layout are:

typedef enum VkDescriptorSetLayoutCreateFlagBits {
    VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT = 0x00000002,
    VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR = 0x00000001,
    VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT_EXT =
    VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT,
} VkDescriptorSetLayoutCreateFlagBits;

• VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR specifies that descriptor sets must not be allocated using this layout, and descriptors are instead pushed by vkCmdPushDescriptorSetKHR.
• **VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT** specifies that descriptor sets using this layout **must** be allocated from a descriptor pool created with the **VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT** bit set. Descriptor set layouts created with this bit set have alternate limits for the maximum number of descriptors per-stage and per-pipeline layout. The non-UpdateAfterBind limits only count descriptors in sets created without this flag. The UpdateAfterBind limits count all descriptors, but the limits **may** be higher than the non-UpdateAfterBind limits.

```c
typedef VkFlags VkDescriptorSetLayoutCreateFlags;
```

`VkDescriptorSetLayoutCreateFlags` is a bitmask type for setting a mask of zero or more `VkDescriptorSetLayoutCreateFlagBits`.

The `VkDescriptorSetLayoutBinding` structure is defined as:

```c
typedef struct VkDescriptorSetLayoutBinding {
    uint32_t binding;
    VkDescriptorType descriptorType;
    uint32_t descriptorCount;
    VkShaderStageFlags stageFlags;
    const VkSampler* pImmutableSamplers;
} VkDescriptorSetLayoutBinding;
```

- **binding** is the binding number of this entry and corresponds to a resource of the same binding number in the shader stages.

- **descriptorType** is a `VkDescriptorType` specifying which type of resource descriptors are used for this binding.

- **descriptorCount** is the number of descriptors contained in the binding, accessed in a shader as an array, except if `descriptorType` is `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` in which case `descriptorCount` is the size in bytes of the inline uniform block. If `descriptorCount` is zero this binding entry is reserved and the resource **must** not be accessed from any stage via this binding within any pipeline using the set layout.

- **stageFlags** member is a bitmask of `VkShaderStageFlagBits` specifying which pipeline shader stages **can** access a resource for this binding. `VK_SHADER_STAGE_ALL` is a shorthand specifying that all defined shader stages, including any additional stages defined by extensions, **can** access the resource.

If a shader stage is not included in `stageFlags`, then a resource **must** not be accessed from that stage via this binding within any pipeline using the set layout. Other than input attachments which are limited to the fragment shader, there are no limitations on what combinations of stages **can** use a descriptor binding, and in particular a binding **can** be used by both graphics stages and the compute stage.

- **pImmutableSamplers** affects initialization of samplers. If `descriptorType` specifies a `VK_DESCRIPTOR_TYPE_SAMPLER` or `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER` type descriptor, then `pImmutableSamplers` **can** be used to initialize a set of *immutable samplers*. Immutable samplers
are permanently bound into the set layout and must not be changed; updating a `VK_DESCRIPTOR_TYPE_SAMPLER` descriptor with immutable samplers is not allowed and updates to a `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER` descriptor with immutable samplers does not modify the samplers (the image views are updated, but the sampler updates are ignored). If `pImmutableSamplers` is not `NULL`, then it points to an array of sampler handles that will be copied into the set layout and used for the corresponding binding. Only the sampler handles are copied; the sampler objects must not be destroyed before the final use of the set layout and any descriptor pools and sets created using it. If `pImmutableSamplers` is `NULL`, then the sampler slots are dynamic and sampler handles must be bound into descriptor sets using this layout. If `descriptorType` is not one of these descriptor types, then `pImmutableSamplers` is ignored.

The above layout definition allows the descriptor bindings to be specified sparsely such that not all binding numbers between 0 and the maximum binding number need to be specified in the `pBindings` array. Bindings that are not specified have a `descriptorCount` and `stageFlags` of zero, and the value of `descriptorType` is undefined. However, all binding numbers between 0 and the maximum binding number in the `VkDescriptorSetLayoutCreateInfo::pBindings` array may consume memory in the descriptor set layout even if not all descriptor bindings are used, though it should not consume additional memory from the descriptor pool.

Note
The maximum binding number specified should be as compact as possible to avoid wasted memory.

Valid Usage

- If `descriptorType` is `VK_DESCRIPTOR_TYPE_SAMPLER` or `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`, and `descriptorCount` is not 0 and `pImmutableSamplers` is not `NULL`, `pImmutableSamplers` must be a valid pointer to an array of `descriptorCount` valid `VkSampler` handles.

- If `descriptorType` is `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then `descriptorCount` must be a multiple of 4.

- If `descriptorType` is `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then `descriptorCount` must be less than or equal to `VkPhysicalDeviceInlineUniformBlockPropertiesEXT::maxInlineUniformBlockSize`.

- If `descriptorCount` is not 0, `stageFlags` must be a valid combination of `VkShaderStageFlagBits` values.

- If `descriptorType` is `VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT` and `descriptorCount` is not 0, then `stageFlags` must be 0 or `VK_SHADER_STAGE_FRAGMENT_BIT`.

- The sampler objects indicated by `pImmutableSamplers` must not have a `borderColor` with one of the values `VK_BORDER_COLOR_FLOAT_CUSTOM_EXT` or `VK_BORDER_COLOR_INT_CUSTOM_EXT`.
Valid Usage (Implicit)

- descriptorType must be a valid VkDescriptorType value

If the pNext chain of a VkDescriptorSetLayoutCreateInfo structure includes a slink::VkDescriptorSetLayoutBindingFlagsCreateInfo structure, then that structure includes an array of flags, one for each descriptor set layout binding.

The VkDescriptorSetLayoutBindingFlagsCreateInfo structure is defined as:

```c
typedef struct VkDescriptorSetLayoutBindingFlagsCreateInfo {
    VkStructureType             sType;
    const void*              pNext;
    uint32_t                     bindingCount;
    const VkDescriptorBindingFlags* pBindingFlags;
} VkDescriptorSetLayoutBindingFlagsCreateInfo;
```

or the equivalent

```c
typedef VkDescriptorSetLayoutBindingFlagsCreateInfo
 VkDescriptorSetLayoutBindingFlagsCreateInfoEXT;
```

- sType is the type of this structure.
- pNext is NULL or a pointer to an extension-specific structure.
- bindingCount is zero or the number of elements in pBindingFlags.
- pBindingFlags is a pointer to an array of VkDescriptorBindingFlags bitfields, one for each descriptor set layout binding.

If bindingCount is zero or if this structure is not included in the pNext chain, the VkDescriptorBindingFlags for each descriptor set layout binding is considered to be zero. Otherwise, the descriptor set layout binding at VkDescriptorSetLayoutCreateInfo::pBindings[i] uses the flags in pBindingFlags[i].
Valid Usage

- If `bindingCount` is not zero, `bindingCount` must equal `VkDescriptorSetLayoutCreateInfo::bindingCount`.

- If `VkDescriptorSetLayoutCreateInfo::flags` includes `VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR`, then all elements of `pBindingFlags` must not include `VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT`, `VK_DESCRIPTOR_BINDING_UPDATE_UNUSED WHILE PENDING_BIT`, or `VK_DESCRIPTOR_BINDING VARIABLE_DESCRIPTOR_COUNT_BIT`.

- If an element of `pBindingFlags` includes `VK_DESCRIPTOR_BINDING VARIABLE_DESCRIPTOR_COUNT_BIT`, then all other elements of `VkDescriptorSetLayoutCreateInfo::pBindings` must have a smaller value of `binding`.

- If `VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingUniformBufferUpdateAfterBind` is not enabled, all bindings with descriptor type `VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER` must not use `VK_DESCRIPTOR_BINDING_UPDATE AFTER BIND_BIT`.

- If `VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingSampledImageUpdateAfterBind` is not enabled, all bindings with descriptor type `VK_DESCRIPTOR_TYPE_SAMPLER`, `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`, or `VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE` must not use `VK_DESCRIPTOR_BINDING_UPDATE AFTER BIND_BIT`.

- If `VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingStorageImageUpdateAfterBind` is not enabled, all bindings with descriptor type `VK_DESCRIPTOR_TYPE_STORAGE_IMAGE` must not use `VK_DESCRIPTOR_BINDING_UPDATE AFTER BIND_BIT`.

- If `VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingStorageBufferUpdateAfterBind` is not enabled, all bindings with descriptor type `VK_DESCRIPTOR_TYPE STORAGE_BUFFER` must not use `VK_DESCRIPTOR_BINDING_UPDATE AFTER BIND_BIT`.

- If `VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingUniformTexelBufferUpdateAfterBind` is not enabled, all bindings with descriptor type `VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER` must not use `VK_DESCRIPTOR_BINDING_UPDATE AFTER BIND_BIT`.

- If `VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingStorageTexelBufferUpdateAfterBind` is not enabled, all bindings with descriptor type `VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER` must not use `VK_DESCRIPTOR_BINDING_UPDATE AFTER BIND_BIT`.

- If `VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingInlineUniformBlockUpdateAfterBind` is not enabled, all bindings with descriptor type `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` must not use `VK_DESCRIPTOR_BINDING_UPDATE AFTER BIND_BIT`.

- All bindings with descriptor type `VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT`, `VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC`, or `VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC` must not use `VK_DESCRIPTOR_BINDING_UPDATE AFTER BIND_BIT`.

- If `VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingUniformBlockUpdateAfterBind` is not enabled, all bindings with descriptor type `VK_DESCRIPTOR_TYPE_UNIFORM_BLOCK_EXT` must not use `VK_DESCRIPTOR_BINDING_UPDATE AFTER BIND_BIT`.

680 | Chapter 13. Resource Descriptors
::descriptorBindingUpdateUnusedWhilePending is not enabled, all elements of pBindingFlags must not include VK_DESCRIPTOR_BINDING_UPDATE_UNUSED_WHILE_PENDING_BIT

- If VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingPartiallyBound is not enabled, all elements of pBindingFlags must not include VK_DESCRIPTOR_BINDING_PARTIALLY_BOUND_BIT

- If VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingVariableDescriptorCount is not enabled, all elements of pBindingFlags must not include VK_DESCRIPTOR_BINDING_VARIABLE_DESCRIPTOR_COUNT_BIT

- If an element of pBindingFlags includes VK_DESCRIPTOR_BINDING_VARIABLE_DESCRIPTOR_COUNT_BIT, that element's descriptorType must not be VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC or VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC

Valid Usage (Implicit)

- sType must be VK_STRUCTURE_TYPE_DESCRIPTOR_SET_LAYOUT_BINDING_FLAGS_CREATE_INFO

- If bindingCount is not 0, and pBindingFlags is not NULL, pBindingFlags must be a valid pointer to an array of bindingCount valid combinations of VkDescriptorBindingFlagBits values

Bits which can be set in each element of VkDescriptorSetLayoutBindingFlagsCreateInfo::pBindingFlags to specify options for the corresponding descriptor set layout binding are:

```c
typedef enum VkDescriptorBindingFlagBits {
  VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT = 0x00000001,
  VK_DESCRIPTOR_BINDING_UPDATE_UNUSED_WHILE_PENDING_BIT = 0x00000002,
  VK_DESCRIPTOR_BINDING_PARTIALLY_BOUND_BIT = 0x00000004,
  VK_DESCRIPTOR_BINDING_VARIABLE_DESCRIPTOR_COUNT_BIT = 0x00000008,
  VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT_EXT = VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT,
  VK_DESCRIPTOR_BINDING_UPDATE_UNUSED_WHILE_PENDING_BIT_EXT = VK_DESCRIPTOR_BINDING_UPDATE_UNUSED_WHILE_PENDING_BIT,
  VK_DESCRIPTOR_BINDING_PARTIALLY_BOUND_BIT_EXT = VK_DESCRIPTOR_BINDING_PARTIALLY_BOUND_BIT,
  VK_DESCRIPTOR_BINDING_VARIABLE_DESCRIPTOR_COUNT_BIT_EXT = VK_DESCRIPTOR_BINDING_VARIABLE_DESCRIPTOR_COUNT_BIT,
} VkDescriptorBindingFlagBits;
```

or the equivalent

```c
typedef VkDescriptorBindingFlagBits VkDescriptorBindingFlagBitsEXT;
```

- VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT indicates that if descriptors in this binding are updated between when the descriptor set is bound in a command buffer and when that
command buffer is submitted to a queue, then the submission will use the most recently set descriptors for this binding and the updates do not invalidate the command buffer. Descriptor bindings created with this flag are also partially exempt from the external synchronization requirement in `vkUpdateDescriptorSetWithTemplateKHR` and `vkUpdateDescriptorSets`. Multiple descriptors with this flag set can be updated concurrently in different threads, though the same descriptor must not be updated concurrently by two threads. Descriptors with this flag set can be updated concurrently with the set being bound to a command buffer in another thread, but not concurrently with the set being reset or freed.

- **VK_DESCRIPTOR_BINDING_PARTIALLY_BOUND_BIT** indicates that descriptors in this binding that are not dynamically used need not contain valid descriptors at the time the descriptors are consumed. A descriptor is dynamically used if any shader invocation executes an instruction that performs any memory access using the descriptor.

- **VK_DESCRIPTOR_BINDING_UPDATE_UNUSED_WHILE_PENDING_BIT** indicates that descriptors in this binding can be updated after a command buffer has bound this descriptor set, or while a command buffer that uses this descriptor set is pending execution, as long as the descriptors that are updated are not used by those command buffers. If **VK_DESCRIPTOR_BINDING_PARTIALLY_BOUND_BIT** is also set, then descriptors can be updated as long as they are not dynamically used by any shader invocations. If **VK_DESCRIPTOR_BINDING_PARTIALLY_BOUND_BIT** is not set, then descriptors can be updated as long as they are not statically used by any shader invocations.

- **VK_DESCRIPTOR_BINDING_VARIABLE_DESCRIPTOR_COUNT_BIT** indicates that this descriptor binding has a variable size that will be specified when a descriptor set is allocated using this layout. The value of `descriptorCount` is treated as an upper bound on the size of the binding. This must only be used for the last binding in the descriptor set layout (i.e. the binding with the largest value of `binding`). For the purposes of counting against limits such as `maxDescriptorSet` and `maxPerStageDescriptor`, the full value of `descriptorCount` is counted, except for descriptor bindings with a descriptor type of `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` where `descriptorCount` specifies the upper bound on the byte size of the binding, thus it counts against the `maxInlineUniformBlockSize` limit instead.

**Note**

Note that while **VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT** and **VK_DESCRIPTOR_BINDING_UPDATE_UNUSED_WHILE_PENDING_BIT** both involve updates to descriptor sets after they are bound, **VK_DESCRIPTOR_BINDING_UPDATE_UNUSED_WHILE_PENDING_BIT** is a weaker requirement since it is only about descriptors that are not used, whereas **VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT** requires the implementation to observe updates to descriptors that are used.

typedef VkFlags VkDescriptorBindingFlags;

or the equivalent

typedef VkDescriptorBindingFlags VkDescriptorBindingFlagsEXT;
**VkDescriptorBindingFlags** is a bitmask type for setting a mask of zero or more **VkDescriptorBindingFlagBits**.

To query information about whether a descriptor set layout can be created, call:

```c
void vkGetDescriptorSetLayoutSupportKHR(
    VkDevice                                    device,
    const VkDescriptorSetLayoutCreateInfo*      pCreateInfo,
    VkDescriptorSetLayoutSupport*               pSupport);
```

- **device** is the logical device that would create the descriptor set layout.
- **pCreateInfo** is a pointer to a **VkDescriptorSetLayoutCreateInfo** structure specifying the state of the descriptor set layout object.
- **pSupport** is a pointer to a **VkDescriptorSetLayoutSupport** structure, in which information about support for the descriptor set layout object is returned.

Some implementations have limitations on what fits in a descriptor set which are not easily expressible in terms of existing limits like `maxDescriptorSet`*, for example if all descriptor types share a limited space in memory but each descriptor is a different size or alignment. This command returns information about whether a descriptor set satisfies this limit. If the descriptor set layout satisfies the **VkPhysicalDeviceMaintenance3Properties::maxPerSetDescriptors** limit, this command is guaranteed to return **VK_TRUE** in **VkDescriptorSetLayoutSupport::supported**. If the descriptor set layout exceeds the **VkPhysicalDeviceMaintenance3Properties::maxPerSetDescriptors** limit, whether the descriptor set layout is supported is implementation-dependent and may depend on whether the descriptor sizes and alignments cause the layout to exceed an internal limit.

This command does not consider other limits such as `maxPerStageDescriptor`*, and so a descriptor set layout that is supported according to this command must still satisfy the pipeline layout limits such as `maxPerStageDescriptor`* in order to be used in a pipeline layout.

**Note**

This is a **VkDevice** query rather than **VkPhysicalDevice** because the answer may depend on enabled features.

### Valid Usage (Implicit)

- **device** **must** be a valid **VkDevice** handle
- **pCreateInfo** **must** be a valid pointer to a valid **VkDescriptorSetLayoutCreateInfo** structure
- **pSupport** **must** be a valid pointer to a **VkDescriptorSetLayoutSupport** structure

Information about support for the descriptor set layout is returned in a **VkDescriptorSetLayoutSupport** structure:
typedef struct VkDescriptorSetLayoutSupport {
    VkStructureType sType;
    void* pNext;
    VkBool32 supported;
} VkDescriptorSetLayoutSupport;

or the equivalent

typedef VkDescriptorSetLayoutSupport VkDescriptorSetLayoutSupportKHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **supported** specifies whether the descriptor set layout can be created.

**supported** is set to VK_TRUE if the descriptor set can be created, or else is set to VK_FALSE.

**Valid Usage (Implicit)**

- **sType** must be VK_STRUCTURE_TYPE_DESCRIPTOR_SET_LAYOUT_SUPPORT
- **pNext** must be NULL or a pointer to a valid instance of VkDescriptorSetVariableDescriptorCountLayoutSupport
- The **sType** value of each struct in the **pNext** chain must be unique

If the **pNext** chain of a VkDescriptorSetLayoutSupport structure includes a VkDescriptorSetVariableDescriptorCountLayoutSupport structure, then that structure returns additional information about whether the descriptor set layout is supported.

typedef struct VkDescriptorSetVariableDescriptorCountLayoutSupport {
    VkStructureType sType;
    void* pNext;
    uint32_t maxVariableDescriptorCount;
} VkDescriptorSetVariableDescriptorCountLayoutSupport;

or the equivalent

typedef VkDescriptorSetVariableDescriptorCountLayoutSupport VkDescriptorSetVariableDescriptorCountLayoutSupportEXT;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **maxVariableDescriptorCount** indicates the maximum number of descriptors supported in the highest numbered binding of the layout, if that binding is variable-sized. If the highest
numbered binding of the layout has a descriptor type of
VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT then maxVariableDescriptorCount indicates the
maximum byte size supported for the binding, if that binding is variable-sized.

If the create info includes a variable-sized descriptor, then supported is determined assuming the
requested size of the variable-sized descriptor, and maxVariableDescriptorCount is set to the
maximum size of that descriptor that can be successfully created (which is greater than or equal to
the requested size passed in). If the create info does not include a variable-sized descriptor or if the
VkPhysicalDeviceDescriptorIndexingFeatures::descriptorBindingVariableDescriptorCount feature is
not enabled, then maxVariableDescriptorCount is set to zero. For the purposes of this command, a
variable-sized descriptor binding with a descriptorCount of zero is treated as if the descriptorCount
is one, and thus the binding is not ignored and the maximum descriptor count will be returned. If
the layout is not supported, then the value written to maxVariableDescriptorCount is undefined.

Valid Usage (Implicit)

• sType must be
  VK_STRUCTURE_TYPE_DESCRIPTOR_SET_VARIABLE_DESCRIPTOR_COUNT_LAYOUT_SUPPORT

The following examples show a shader snippet using two descriptor sets, and application code that
creates corresponding descriptor set layouts.

GLSL example

```glsl
// binding to a single sampled image descriptor in set 0
// layout (set=0, binding=0) uniform texture2D mySampledImage;

// binding to an array of sampled image descriptors in set 0
// layout (set=0, binding=1) uniform texture2D myArrayOfSampledImages[12];

// binding to a single uniform buffer descriptor in set 1
// layout (set=1, binding=0) uniform myUniformBuffer
{  vec4 myElement[32]; }
```

Chapter 13. Resource Descriptors | 685
SPIR-V example

```
...%1 = OpExtInstImport "GLSL.std.450"
...
OpName %9 "mySampledImage"
OpName %14 "myArrayOfSampledImages"
OpName %18 "myUniformBuffer"
OpMemberName %18 0 "myElement"
OpName %20 ""
OpDecorate %9 DescriptorSet 0
OpDecorate %9 Binding 0
OpDecorate %14 DescriptorSet 0
OpDecorate %14 Binding 1
OpDecorate %17 ArrayStride 16
OpMemberDecorate %18 0 Offset 0
OpDecorate %18 Block
OpDecorate %20 DescriptorSet 1
OpDecorate %20 Binding 0
%2 = OpTypeVoid
%3 = OpTypeFunction %2
%6 = OpTypeFloat 32
%7 = OpTypeImage %6 2D 0 0 0 1 Unknown

%9 = OpVariable %8 UniformConstant
%10 = OpTypeInt 32 0
%11 = OpConstant %10 12
%12 = OpTypeArray %7 %11
%13 = OpTypePointer UniformConstant %12
%14 = OpVariable %13 UniformConstant
%15 = OpTypeVector %6 4
%16 = OpConstant %10 32
%17 = OpTypeArray %15 %16
%18 = OpTypeStruct %17
%19 = OpTypePointer Uniform %18
%20 = OpVariable %19 Uniform
...```

API example

```c
VkResult myResult;

const VkDescriptorSetLayoutBinding myDescriptorSetLayoutBinding[] = {
    // binding to a single image descriptor
    {
        0,                  // binding
        VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE, // descriptorType
        1,                  // descriptorCount
        VK_SHADER_STAGE_FRAGMENT_BIT,    // stageFlags
```
// binding to an array of image descriptors
{
  1, // binding
  VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE, // descriptorType
  12, // descriptorCount
  VK_SHADER_STAGE_FRAGMENT_BIT, // stageFlags
  NULL // pImmutableSamplers
},

// binding to a single uniform buffer descriptor
{
  0, // binding
  VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER, // descriptorType
  1, // descriptorCount
  VK_SHADER_STAGE_FRAGMENT_BIT, // stageFlags
  NULL // pImmutableSamplers
}

const VkDescriptorSetLayoutCreateInfo myDescriptorSetLayoutCreateInfo[] =
{
  // Create info for first descriptor set with two descriptor bindings
  {
    VK_STRUCTURE_TYPE_DESCRIPTOR_SET_LAYOUT_CREATE_INFO, // sType
    NULL, // pNext
    0, // flags
    2, // bindingCount
    &myDescriptorSetLayoutBinding[0] // pBindings
  },

  // Create info for second descriptor set with one descriptor binding
  {
    VK_STRUCTURE_TYPE_DESCRIPTOR_SET_LAYOUT_CREATE_INFO, // sType
    NULL, // pNext
    0, // flags
    1, // bindingCount
  }
};

VkDescriptorSetLayout myDescriptorSetLayout[2];

// Create first descriptor set layout
myResult = vkCreateDescriptorSetLayout(
  myDevice,
  &myDescriptorSetLayoutCreateInfo[0],

To destroy a descriptor set layout, call:

```c
void vkDestroyDescriptorSetLayout(  
    VkDevice                                    device,  
    VkDescriptorSetLayout                       descriptorSetLayout,  
    const VkAllocationCallbacks*                pAllocator);
```

- `device` is the logical device that destroys the descriptor set layout.
- `descriptorSetLayout` is the descriptor set layout to destroy.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

### Valid Usage

- If `VkAllocationCallbacks` were provided when `descriptorSetLayout` was created, a compatible set of callbacks must be provided here.
- If no `VkAllocationCallbacks` were provided when `descriptorSetLayout` was created, `pAllocator` must be NULL.

### Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle.
- If `descriptorSetLayout` is not `VK_NULL_HANDLE`, `descriptorSetLayout` must be a valid `VkDescriptorSetLayout` handle.
- If `pAllocator` is not NULL, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure.
- If `descriptorSetLayout` is a valid handle, it must have been created, allocated, or retrieved from `device`.

```c
NULL,  
&myDescriptorSetLayout[0]);
//  // Create second descriptor set layout  //  myResult = vkCreateDescriptorSetLayout(  
myDevice,  
&myDescriptorSetLayoutCreateInfo[1],  
NULL,  
&myDescriptorSetLayout[1]);
```
13.2.2. Pipeline Layouts

Access to descriptor sets from a pipeline is accomplished through a pipeline layout. Zero or more descriptor set layouts and zero or more push constant ranges are combined to form a pipeline layout object describing the complete set of resources that can be accessed by a pipeline. The pipeline layout represents a sequence of descriptor sets with each having a specific layout. This sequence of layouts is used to determine the interface between shader stages and shader resources. Each pipeline is created using a pipeline layout.

Pipeline layout objects are represented by VkPipelineLayout handles:

```
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkPipelineLayout)
```

To create a pipeline layout, call:

```
VkResult vkCreatePipelineLayout(
    VkDevice                                    device,
    const VkPipelineLayoutCreateInfo*           pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkPipelineLayout*                           pPipelineLayout);
```

- **device** is the logical device that creates the pipeline layout.
- **pCreateInfo** is a pointer to a VkPipelineLayoutCreateInfo structure specifying the state of the pipeline layout object.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pPipelineLayout** is a pointer to a VkPipelineLayout handle in which the resulting pipeline layout object is returned.

Valid Usage (Implicit)

- **device** must be a valid VkDevice handle
- **pCreateInfo** must be a valid pointer to a valid VkPipelineLayoutCreateInfo structure
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid VkAllocationCallbacks structure
- **pPipelineLayout** must be a valid pointer to a VkPipelineLayout handle
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

The `VkPipelineLayoutCreateInfo` structure is defined as:

```c
typedef struct VkPipelineLayoutCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkPipelineLayoutCreateFlags flags;
    uint32_t setLayoutCount;
    const VkDescriptorSetLayout* pSetLayouts;
    uint32_t pushConstantRangeCount;
    const VkPushConstantRange* pPushConstantRanges;
} VkPipelineLayoutCreateInfo;
```

• `sType` is the type of this structure.
• `pNext` is NULL or a pointer to an extension-specific structure.
• `flags` is reserved for future use.
• `setLayoutCount` is the number of descriptor sets included in the pipeline layout.
• `pSetLayouts` is a pointer to an array of `VkDescriptorSetLayout` objects.
• `pushConstantRangeCount` is the number of push constant ranges included in the pipeline layout.
• `pPushConstantRanges` is a pointer to an array of `VkPushConstantRange` structures defining a set of push constant ranges for use in a single pipeline layout. In addition to descriptor set layouts, a pipeline layout also describes how many push constants can be accessed by each stage of the pipeline.

**Note**

Push constants represent a high speed path to modify constant data in pipelines that is expected to outperform memory-backed resource updates.
Valid Usage

- `setLayoutCount` must be less than or equal to `VkPhysicalDeviceLimits::maxBoundDescriptorSets`

  - The total number of descriptors in descriptor set layouts created without the `VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT` bit set with a descriptorType of `VK_DESCRIPTOR_TYPE_SAMPLER` and `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER` accessible to any given shader stage across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceLimits::maxPerStageDescriptorSamplers`

  - The total number of descriptors in descriptor set layouts created without the `VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT` bit set with a descriptorType of `VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER` and `VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC` accessible to any given shader stage across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceLimits::maxPerStageDescriptorUniformBuffers`

  - The total number of descriptors in descriptor set layouts created without the `VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT` bit set with a descriptorType of `VK_DESCRIPTOR_TYPE_STORAGE_BUFFER` and `VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC` accessible to any given shader stage across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceLimits::maxPerStageDescriptorStorageBuffers`

  - The total number of descriptors in descriptor set layouts created without the `VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT` bit set with a descriptorType of `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`, `VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE`, and `VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER` accessible to any given shader stage across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceLimits::maxPerStageDescriptorSampledImages`

  - The total number of descriptors in descriptor set layouts created without the `VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT` bit set with a descriptorType of `VK_DESCRIPTOR_TYPE_STORAGE_IMAGE`, and `VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER` accessible to any given shader stage across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceLimits::maxPerStageDescriptorStorageImages`

  - The total number of descriptors in descriptor set layouts created without the `VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT` bit set with a descriptorType of `VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT` accessible to any given shader stage across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceLimits::maxPerStageDescriptorInputAttachments`

  - The total number of bindings in descriptor set layouts created without the `VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT` bit set with a descriptorType of `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` accessible to any given shader stage across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceInlineUniformBlockPropertiesEXT::maxPerStageDescriptorInlineUniformBlocks`

  - The total number of descriptors with a descriptorType of `VK_DESCRIPTOR_TYPE_SAMPLER` and `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER` accessible to any given shader stage across all elements of `pSetLayouts` must be less than or equal to
VkPhysicalDeviceDescriptorIndexingProperties::maxPerStageDescriptorUpdateAfterBindSamplers

• The total number of descriptors with a descriptorType of VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER and VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC accessible to any given shader stage across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceDescriptorIndexingProperties::maxPerStageDescriptorUpdateAfterBindUniformBuffers

• The total number of descriptors with a descriptorType of VK_DESCRIPTOR_TYPE_STORAGE_BUFFER and VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC accessible to any given shader stage across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceDescriptorIndexingProperties::maxPerStageDescriptorUpdateAfterBindStorageBuffers

• The total number of descriptors with a descriptorType of VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE, and VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER accessible to any given shader stage across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceDescriptorIndexingProperties::maxPerStageDescriptorUpdateAfterBindSampledImages

• The total number of descriptors with a descriptorType of VK_DESCRIPTOR_TYPE_STORAGE_IMAGE, and VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER accessible to any given shader stage across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceDescriptorIndexingProperties::maxPerStageDescriptorUpdateAfterBindStorageImages

• The total number of descriptors with a descriptorType of VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT accessible to any given shader stage across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceDescriptorIndexingProperties::maxPerStageDescriptorUpdateAfterBindInputAttachments

• The total number of bindings with a descriptorType of VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT accessible to any given shader stage across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceInlineUniformBlockPropertiesEXT::maxPerStageDescriptorUpdateAfterBindInlineUniformBlocks

• The total number of descriptors in descriptor set layouts created without the VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT bit set with a descriptorType of VK_DESCRIPTOR_TYPE_SAMPLER and VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceLimits::maxDescriptorSetSamplers

• The total number of descriptors in descriptor set layouts created without the VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT bit set with a descriptorType of VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceLimits::maxDescriptorSetUniformBuffers

• The total number of descriptors in descriptor set layouts created without the VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT bit set with a descriptorType
of VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceLimits::maxDescriptorSetUniformBuffersDynamic

- The total number of descriptors in descriptor set layouts created without the VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT bit set with a descriptorType of VK_DESCRIPTOR_TYPE_STORAGE_BUFFER accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceLimits::maxDescriptorSetStorageBuffers

- The total number of descriptors in descriptor set layouts created without the VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT bit set with a descriptorType of VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceLimits::maxDescriptorSetStorageBuffersDynamic

- The total number of descriptors in descriptor set layouts created without the VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT bit set with a descriptorType of VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE, and VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceLimits::maxDescriptorSetSampledImages

- The total number of descriptors in descriptor set layouts created without the VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT bit set with a descriptorType of VK_DESCRIPTOR_TYPE_STORAGE_IMAGE, and VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceLimits::maxDescriptorSetStorageImages

- The total number of descriptors in descriptor set layouts created without the VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT bit set with a descriptorType of VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceLimits::maxDescriptorSetInputAttachments

- The total number of bindings in descriptor set layouts created without the VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT bit set with a descriptorType of VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceInlineUniformBlockPropertiesEXT::maxDescriptorSetInlineUniformBlocks

- The total number of descriptors of the type VK_DESCRIPTOR_TYPE_SAMPLER and VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceDescriptorIndexingProperties::maxDescriptorSetUpdateAfterBindSamplers

- The total number of descriptors of the type VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceDescriptorIndexingProperties::maxDescriptorSetUpdateAfterBindUniformBuffers

- The total number of descriptors of the type VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC accessible across all shader stages and across all elements of pSetLayouts must be less than or equal to VkPhysicalDeviceDescriptorIndexingProperties::maxDescriptorSetUpdateAfterBindUniformBuffersDynamic
The total number of descriptors of the type `VK_DESCRIPTOR_TYPE_STORAGE_BUFFER` accessible across all shader stages and across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceDescriptorIndexingProperties::maxDescriptorSetUpdateAfterBindUniformBuffersDynamic`.

The total number of descriptors of the type `VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC` accessible across all shader stages and across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceDescriptorIndexingProperties::maxDescriptorSetUpdateAfterBindStorageBuffersDynamic`.

The total number of descriptors of the type `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`, `VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE`, and `VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER` accessible across all shader stages and across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceDescriptorIndexingProperties::maxDescriptorSetUpdateAfterBindSampledImages`.

The total number of descriptors of the type `VK_DESCRIPTOR_TYPE_STORAGE_IMAGE`, and `VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER` accessible across all shader stages and across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceDescriptorIndexingProperties::maxDescriptorSetUpdateAfterBindStorageImages`.

The total number of descriptors of the type `VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT` accessible across all shader stages and across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceDescriptorIndexingProperties::maxDescriptorSetUpdateAfterBindInputAttachments`.

The total number of bindings with a `descriptorType` of `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` accessible across all shader stages and across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceInlineUniformBlockPropertiesEXT::maxDescriptorSetUpdateAfterBindInlineUniformBlocks`.

Any two elements of `pPushConstantRanges` must not include the same stage in `stageFlags`.

`pSetLayouts` must not contain more than one descriptor set layout that was created with `VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR` set.

The total number of bindings with a `descriptorType` of `VK_DESCRIPTOR_TYPE_ACCELERATION_STRUCTURE_KHR` accessible across all shader stages and across all elements of `pSetLayouts` must be less than or equal to `VkPhysicalDeviceRayTracingPropertiesKHR::maxDescriptorSetAccelerationStructures`.
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_PIPELINE_LAYOUT_CREATE_INFO`
- `pNext` must be `NULL`
- `flags` must be `0`
- If `setLayoutCount` is not `0`, `pSetLayouts` must be a valid pointer to an array of `setLayoutCount` valid `VkDescriptorSetLayout` handles
- If `pushConstantRangeCount` is not `0`, `pPushConstantRanges` must be a valid pointer to an array of `pushConstantRangeCount` valid `VkPushConstantRange` structures

```c
typedef VkFlags VkPipelineLayoutCreateFlags;
```

`VkPipelineLayoutCreateFlags` is a bitmask type for setting a mask, but is currently reserved for future use.

The `VkPushConstantRange` structure is defined as:

```c
typedef struct VkPushConstantRange {
    VkShaderStageFlags    stageFlags;
    uint32_t              offset;
    uint32_t              size;
} VkPushConstantRange;
```

- `stageFlags` is a set of stage flags describing the shader stages that will access a range of push constants. If a particular stage is not included in the range, then accessing members of that range of push constants from the corresponding shader stage will return undefined values.
- `offset` and `size` are the start offset and size, respectively, consumed by the range. Both `offset` and `size` are in units of bytes and must be a multiple of 4. The layout of the push constant variables is specified in the shader.

Valid Usage

- `offset` must be less than `VkPhysicalDeviceLimits::maxPushConstantsSize`
- `offset` must be a multiple of 4
- `size` must be greater than 0
- `size` must be a multiple of 4
- `size` must be less than or equal to `VkPhysicalDeviceLimits::maxPushConstantsSize` minus `offset`
Valid Usage (Implicit)

- stageFlags must be a valid combination of VkShaderStageFlagBits values
- stageFlags must not be 0

Once created, pipeline layouts are used as part of pipeline creation (see Pipelines), as part of binding descriptor sets (see Descriptor Set Binding), and as part of setting push constants (see Push Constant Updates). Pipeline creation accepts a pipeline layout as input, and the layout may be used to map (set, binding, arrayElement) tuples to implementation resources or memory locations within a descriptor set. The assignment of implementation resources depends only on the bindings defined in the descriptor sets that comprise the pipeline layout, and not on any shader source.

All resource variables statically used in all shaders in a pipeline must be declared with a (set,binding,arrayElement) that exists in the corresponding descriptor set layout and is of an appropriate descriptor type and includes the set of shader stages it is used by in stageFlags. The pipeline layout can include entries that are not used by a particular pipeline, or that are dead-code eliminated from any of the shaders. The pipeline layout allows the application to provide a consistent set of bindings across multiple pipeline compiles, which enables those pipelines to be compiled in a way that the implementation may cheaply switch pipelines without reprogramming the bindings.

Similarly, the push constant block declared in each shader (if present) must only place variables at offsets that are each included in a push constant range with stageFlags including the bit corresponding to the shader stage that uses it. The pipeline layout can include ranges or portions of ranges that are not used by a particular pipeline, or for which the variables have been dead-code eliminated from any of the shaders.

There is a limit on the total number of resources of each type that can be included in bindings in all descriptor set layouts in a pipeline layout as shown in Pipeline Layout Resource Limits. The “Total Resources Available” column gives the limit on the number of each type of resource that can be included in bindings in all descriptor sets in the pipeline layout. Some resource types count against multiple limits. Additionally, there are limits on the total number of each type of resource that can be used in any pipeline stage as described in Shader Resource Limits.

To destroy a pipeline layout, call:

```c
void vkDestroyPipelineLayout(
    VkDevice device,
    VkPipelineLayout pipelineLayout,
    const VkAllocationCallbacks* pAllocator);
```

- **device** is the logical device that destroys the pipeline layout.
- **pipelineLayout** is the pipeline layout to destroy.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.

**Valid Usage**

- If **VkAllocationCallbacks** were provided when **pipelineLayout** was created, a compatible set of callbacks **must** be provided here.

- If no **VkAllocationCallbacks** were provided when **pipelineLayout** was created, **pAllocator** **must** be **NULL**.

- **pipelineLayout** **must** not have been passed to any **vkCmd* command for any command buffers that are still in the recording state when **vkDestroyPipelineLayout** is called.
Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- If `pipelineLayout` is not `VK_NULL_HANDLE`, `pipelineLayout` must be a valid `VkPipelineLayout` handle
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- If `pipelineLayout` is a valid handle, it must have been created, allocated, or retrieved from `device`

Host Synchronization

- Host access to `pipelineLayout` must be externally synchronized

Pipeline Layout Compatibility

Two pipeline layouts are defined to be “compatible for push constants” if they were created with identical push constant ranges. Two pipeline layouts are defined to be “compatible for set N” if they were created with identically defined descriptor set layouts for sets zero through N, and if they were created with identical push constant ranges.

When binding a descriptor set (see Descriptor Set Binding) to set number N, if the previously bound descriptor sets for sets zero through N-1 were all bound using compatible pipeline layouts, then performing this binding does not disturb any of the lower numbered sets. If, additionally, the previous bound descriptor set for set N was bound using a pipeline layout compatible for set N, then the bindings in sets numbered greater than N are also not disturbed.

Similarly, when binding a pipeline, the pipeline can correctly access any previously bound descriptor sets which were bound with compatible pipeline layouts, as long as all lower numbered sets were also bound with compatible layouts.

Layout compatibility means that descriptor sets can be bound to a command buffer for use by any pipeline created with a compatible pipeline layout, and without having bound a particular pipeline first. It also means that descriptor sets can remain valid across a pipeline change, and the same resources will be accessible to the newly bound pipeline.

Implementor’s Note

A consequence of layout compatibility is that when the implementation compiles a pipeline layout and maps pipeline resources to implementation resources, the mechanism for set N should only be a function of sets [0..N].
Note

Place the least frequently changing descriptor sets near the start of the pipeline layout, and place the descriptor sets representing the most frequently changing resources near the end. When pipelines are switched, only the descriptor set bindings that have been invalidated will need to be updated and the remainder of the descriptor set bindings will remain in place.

The maximum number of descriptor sets that *can* be bound to a pipeline layout is queried from physical device properties (see `maxBoundDescriptorSets` in `Limits`).

API example

```cpp
const VkDescriptorSetLayout layouts[] = { layout1, layout2 };  
const VkPushConstantRange ranges[] =
{  
    {  
        VK_PIPELINE_STAGE_VERTEX_SHADER_BIT,  // stageFlags
        0,  // offset
        4,  // size
    },  
    {  
        VK_PIPELINE_STAGE_FRAGMENT_SHADER_BIT,  // stageFlags
        4,  // offset
        4,  // size
    },
};

const VkPipelineLayoutCreateInfo createInfo =
{  
    VK_STRUCTURE_TYPE_PIPELINE_LAYOUT_CREATE_INFO,  // sType
    NULL,  // pNext
    0,  // flags
    2,  // setLayoutCount
    layouts,  // pSetLayouts
    2,  // pushConstantRangeCount
    ranges  // pPushConstantRanges
};

VkPipelineLayout myPipelineLayout;  
myResult = vkCreatePipelineLayout(  
    myDevice,  
    &createInfo,  
    NULL,  
    &myPipelineLayout);
```
13.2.3. Allocation of Descriptor Sets

A *descriptor pool* maintains a pool of descriptors, from which descriptor sets are allocated. Descriptor pools are externally synchronized, meaning that the application **must** not allocate and/or free descriptor sets from the same pool in multiple threads simultaneously.

Descriptor pools are represented by *VkDescriptorPool* handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkDescriptorPool)
```

To create a descriptor pool object, call:

```c
VkResult vkCreateDescriptorPool(
    VkDevice                                    device,
    const VkDescriptorPoolCreateInfo*           pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkDescriptorPool*                           pDescriptorPool);
```

- **device** is the logical device that creates the descriptor pool.
- **pCreateInfo** is a pointer to a *VkDescriptorPoolCreateInfo* structure specifying the state of the descriptor pool object.
- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
- **pDescriptorPool** is a pointer to a *VkDescriptorPool* handle in which the resulting descriptor pool object is returned.

*pAllocator* controls host memory allocation as described in the Memory Allocation chapter.

The created descriptor pool is returned in **pDescriptorPool**.

---

**Valid Usage (Implicit)**

- **device** must be a valid *VkDevice* handle
- **pCreateInfo** must be a valid pointer to a valid *VkDescriptorPoolCreateInfo* structure
- If **pAllocator** is not NULL, **pAllocator** must be a valid pointer to a valid *VkAllocationCallbacks* structure
- **pDescriptorPool** must be a valid pointer to a *VkDescriptorPool* handle
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY
• VK_ERROR_FRAGMENTATION_EXT

Additional information about the pool is passed in a `VkDescriptorPoolCreateInfo` structure:

```c
typedef struct VkDescriptorPoolCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkDescriptorPoolCreateFlags flags;
    uint32_t maxSets;
    uint32_t poolSizeCount;
    const VkDescriptorPoolSize* pPoolSizes;
} VkDescriptorPoolCreateInfo;
```

• `sType` is the type of this structure.
• `pNext` is `NULL` or a pointer to an extension-specific structure.
• `flags` is a bitmask of `VkDescriptorPoolCreateFlagBits` specifying certain supported operations on the pool.
• `maxSets` is the maximum number of descriptor sets that can be allocated from the pool.
• `poolSizeCount` is the number of elements in `pPoolSizes`.
• `pPoolSizes` is a pointer to an array of `VkDescriptorPoolSize` structures, each containing a descriptor type and number of descriptors of that type to be allocated in the pool.

If multiple `VkDescriptorPoolSize` structures appear in the `pPoolSizes` array then the pool will be created with enough storage for the total number of descriptors of each type.

Fragmentation of a descriptor pool is possible and may lead to descriptor set allocation failures. A failure due to fragmentation is defined as failing a descriptor set allocation despite the sum of all outstanding descriptor set allocations from the pool plus the requested allocation requiring no more than the total number of descriptors requested at pool creation. Implementations provide certain guarantees of when fragmentation must not cause allocation failure, as described below.

If a descriptor pool has not had any descriptor sets freed since it was created or most recently reset then fragmentation must not cause an allocation failure (note that this is always the case for a pool created without the `VK_DESCRIPTOR_POOL_CREATE_FREE_DESCRIPTOR_SET_BIT` bit set). Additionally, if all sets allocated from the pool since it was created or most recently reset use the same number of descriptors (of each type) and the requested allocation also uses that same number of descriptors
(of each type), then fragmentation must not cause an allocation failure.

If an allocation failure occurs due to fragmentation, an application can create an additional descriptor pool to perform further descriptor set allocations.

If flags has the VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT bit set, descriptor pool creation may fail with the error VK_ERROR_FRAGMENTATION if the total number of descriptors across all pools (including this one) created with this bit set exceeds maxUpdateAfterBindDescriptorsInAllPools, or if fragmentation of the underlying hardware resources occurs.

Valid Usage

- maxSets must be greater than 0

Valid Usage (Implicit)

- sType must be VK_STRUCTURE_TYPE_DESCRIPTOR_POOL_CREATE_INFO
- pNext must be NULL or a pointer to a valid instance of VkDescriptorPoolInlineUniformBlockCreateInfoEXT
- The sType value of each struct in the pNext chain must be unique
- flags must be a valid combination of VkDescriptorPoolCreateFlagBits values
- pPoolSizes must be a valid pointer to an array of poolSizeCount valid VkDescriptorPoolSize structures
- poolSizeCount must be greater than 0

In order to be able to allocate descriptor sets having inline uniform block bindings the descriptor pool must be created with specifying the inline uniform block binding capacity of the descriptor pool, in addition to the total inline uniform data capacity in bytes which is specified through a VkDescriptorPoolSize structure with a descriptorType value of VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT. This can be done by adding a VkDescriptorPoolInlineUniformBlockCreateInfoEXT structure to the pNext chain of VkDescriptorPoolCreateInfo.

The VkDescriptorPoolInlineUniformBlockCreateInfoEXT structure is defined as:

```c
typedef struct VkDescriptorPoolInlineUniformBlockCreateInfoEXT {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           maxInlineUniformBlockBindings;
} VkDescriptorPoolInlineUniformBlockCreateInfoEXT;
```

- sType is the type of this structure.
- pNext is NULL or a pointer to an extension-specific structure.
• **maxInlineUniformBlockBindings** is the number of inline uniform block bindings to allocate.

### Valid Usage (Implicit)

- **sType must** be **VK_STRUCTURE_TYPE_DESCRIPTOR_POOL_INLINE_UNIFORM_BLOCK_CREATE_INFO_EXT**

Bits which **can** be set in **VkDescriptorPoolCreateInfo::flags** to enable operations on a descriptor pool are:

```c
typedef enum VkDescriptorPoolCreateFlagBits {
    VK_DESCRIPTOR_POOL_CREATE_FREE_DESCRIPTOR_SET_BIT = 0x00000001,
    VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT = 0x00000002,
    VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT_EXT =
    VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT,
} VkDescriptorPoolCreateFlagBits;
```

- **VK_DESCRIPTOR_POOL_CREATE_FREE_DESCRIPTOR_SET_BIT** specifies that descriptor sets **can** return their individual allocations to the pool, i.e. all of **vkAllocateDescriptorSets**, **vkFreeDescriptorSets**, and **vkResetDescriptorPool** are allowed. Otherwise, descriptor sets allocated from the pool **must** not be individually freed back to the pool, i.e. only **vkAllocateDescriptorSets** and **vkResetDescriptorPool** are allowed.

- **VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT** specifies that descriptor sets allocated from this pool **can** include bindings with the **VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT** bit set. It is valid to allocate descriptor sets that have bindings that do not set the **VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT** bit from a pool that has **VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT** set.

```c
typedef VkFlags VkDescriptorPoolCreateFlags;

VkDescriptorPoolCreateFlags is a bitmask type for setting a mask of zero or more VkDescriptorPoolCreateFlagBits.
```

The **VkDescriptorPoolSize** structure is defined as:

```c
typedef struct VkDescriptorPoolSize {
    VkDescriptorType type;
    uint32_t descriptorCount;
} VkDescriptorPoolSize;
```

- **type** is the type of descriptor.

- **descriptorCount** is the number of descriptors of that type to allocate. If **type** is **VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT** then **descriptorCount** is the number of bytes to allocate for descriptors of this type.
When creating a descriptor pool that will contain descriptors for combined image samplers of multi-planar formats, an application needs to account for non-trivial descriptor consumption when choosing the `descriptorCount` value, as indicated by `VkSamplerYcbcrConversionImageFormatProperties::combinedImageSamplerDescriptorCount`.

**Valid Usage**

- `descriptorCount` must be greater than 0
- If `type` is `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then `descriptorCount` must be a multiple of 4

**Valid Usage (Implicit)**

- `type` must be a valid `VkDescriptorType` value

To destroy a descriptor pool, call:

```c
void vkDestroyDescriptorPool(
    VkDevice device,        // device
    VkDescriptorPool descriptorPool,  // descriptorPool
    const VkAllocationCallbacks* pAllocator);  // pAllocator
```

- `device` is the logical device that destroys the descriptor pool.
- `descriptorPool` is the descriptor pool to destroy.
- `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

When a pool is destroyed, all descriptor sets allocated from the pool are implicitly freed and become invalid. Descriptor sets allocated from a given pool do not need to be freed before destroying that descriptor pool.

**Valid Usage**

- All submitted commands that refer to `descriptorPool` (via any allocated descriptor sets) must have completed execution
- If `VkAllocationCallbacks` were provided when `descriptorPool` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `descriptorPool` was created, `pAllocator` must be `NULL`
Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle

- If `descriptorPool` is not `VK_NULL_HANDLE`, `descriptorPool` must be a valid `VkDescriptorPool` handle

- If `pAllocator` is not NULL, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure

- If `descriptorPool` is a valid handle, it must have been created, allocated, or retrieved from `device`

Host Synchronization

- Host access to `descriptorPool` must be externally synchronized

Descriptor sets are allocated from descriptor pool objects, and are represented by `VkDescriptorSet` handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkDescriptorSet)
```

To allocate descriptor sets from a descriptor pool, call:

```c
VkResult vkAllocateDescriptorSets(
    VkDevice                                    device,
    const VkDescriptorSetAllocateInfo*          pAllocateInfo,
    VkDescriptorSet*                            pDescriptorSets);
```

- **device** is the logical device that owns the descriptor pool.

- **pAllocateInfo** is a pointer to a `VkDescriptorSetAllocateInfo` structure describing parameters of the allocation.

- **pDescriptorSets** is a pointer to an array of `VkDescriptorSet` handles in which the resulting descriptor set objects are returned.

The allocated descriptor sets are returned in `pDescriptorSets`.

When a descriptor set is allocated, the initial state is largely uninitialized and all descriptors are undefined. Descriptors also become undefined if the underlying resource is destroyed. Descriptor sets containing undefined descriptors can still be bound and used, subject to the following conditions:

- For descriptor set bindings created with the `VK_DESCRIPTOR_BINDING_PARTIALLY_BOUND_BIT` bit set, all descriptors in that binding that are dynamically used must have been populated before the descriptor set is consumed.

- For descriptor set bindings created without the `VK_DESCRIPTOR_BINDING_PARTIALLY_BOUND_BIT` bit
set, all descriptors in that binding that are statically used must have been populated before the descriptor set is consumed.

- Descriptor bindings with descriptor type of VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT can be undefined when the descriptor set is consumed; though values in that block will be undefined.
- Entries that are not used by a pipeline can have undefined descriptors.

If a call to vkAllocateDescriptorSets would cause the total number of descriptor sets allocated from the pool to exceed the value of VkDescriptorPoolCreateInfo::maxSets used to create pAllocateInfo->descriptorPool, then the allocation may fail due to lack of space in the descriptor pool. Similarly, the allocation may fail due to lack of space if the call to vkAllocateDescriptorSets would cause the number of any given descriptor type to exceed the sum of all the descriptorCount members of each element of VkDescriptorPoolCreateInfo::pPoolSizes with a member equal to that type.

Additionally, the allocation may also fail if a call to vkAllocateDescriptorSets would cause the total number of inline uniform block bindings allocated from the pool to exceed the value of VkDescriptorPoolInlineUniformBlockCreateInfoEXT::maxInlineUniformBlockBindings used to create the descriptor pool.

If the allocation fails due to no more space in the descriptor pool, and not because of system or device memory exhaustion, then VK_ERROR_OUT_OF_POOL_MEMORY must be returned.

vkAllocateDescriptorSets can be used to create multiple descriptor sets. If the creation of any of those descriptor sets fails, then the implementation must destroy all successfully created descriptor set objects from this command, set all entries of the pDescriptorSets array to VK_NULL_HANDLE and return the error.

### Valid Usage (Implicit)

- device must be a valid VkDevice handle
- pAllocateInfo must be a valid pointer to a valid VkDescriptorSetAllocateInfo structure
- pDescriptorSets must be a valid pointer to an array of pAllocateInfo->descriptorSetCount VkDescriptorSet handles
- The value referenced by pAllocateInfo->descriptorSetCount must be greater than 0

### Host Synchronization

- Host access to pAllocateInfo->descriptorPool must be externally synchronized
Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY
• VK_ERROR_FRAGMENTED_POOL
• VK_ERROR_OUT_OF_POOL_MEMORY

The `VkDescriptorSetAllocateInfo` structure is defined as:

```c
typedef struct VkDescriptorSetAllocateInfo {
    VkStructureType sType;
    const void* pNext;
    VkDescriptorPool descriptorPool;
    uint32_t descriptorSetCount;
    const VkDescriptorSetLayout* pSetLayouts;
} VkDescriptorSetAllocateInfo;
```

• `sType` is the type of this structure.
• `pNext` is `NULL` or a pointer to an extension-specific structure.
• `descriptorPool` is the pool which the sets will be allocated from.
• `descriptorSetCount` determines the number of descriptor sets to be allocated from the pool.
• `pSetLayouts` is a pointer to an array of descriptor set layouts, with each member specifying how the corresponding descriptor set is allocated.

Valid Usage

• Each element of `pSetLayouts` must not have been created with `VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR` set
• If any element of `pSetLayouts` was created with the `VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT` bit set, `descriptorPool` must have been created with the `VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT` flag set
**Valid Usage (Implicit)**

- **sType** must be `VK_STRUCTURE_TYPE_DESCRIPTOR_SET_ALLOCATE_INFO`.
- **pNext** must be `NULL` or a pointer to a valid instance of `VkDescriptorSetVariableDescriptorCountAllocateInfo`.
- The `sType` value of each struct in the `pNext` chain must be unique.
- **descriptorPool** must be a valid `VkDescriptorPool` handle.
- **pSetLayouts** must be a valid pointer to an array of **descriptorSetCount** valid `VkDescriptorSetLayout` handles.
- **descriptorSetCount** must be greater than 0.
- Both of **descriptorPool**, and the elements of **pSetLayouts** must have been created, allocated, or retrieved from the same `VkDevice`.

If the `pNext` chain of a `VkDescriptorSetAllocateInfo` structure includes a `VkDescriptorSetVariableDescriptorCountAllocateInfo` structure, then that structure includes an array of descriptor counts for variable descriptor count bindings, one for each descriptor set being allocated.

The `VkDescriptorSetVariableDescriptorCountAllocateInfo` structure is defined as:

```c
typedef struct VkDescriptorSetVariableDescriptorCountAllocateInfo {
    VkStructureType sType;
    const void* pNext;
    uint32_t descriptorSetCount;
    const uint32_t* pDescriptorCounts;
} VkDescriptorSetVariableDescriptorCountAllocateInfo;
```

or the equivalent:

```c
typedef VkDescriptorSetVariableDescriptorCountAllocateInfo
    VkDescriptorSetVariableDescriptorCountAllocateInfoEXT;
```

- **sType** is the type of this structure.
- **pNext** is `NULL` or a pointer to an extension-specific structure.
- **descriptorSetCount** is zero or the number of elements in **pDescriptorCounts**.
- **pDescriptorCounts** is a pointer to an array of descriptor counts, with each member specifying the number of descriptors in a variable descriptor count binding in the corresponding descriptor set being allocated.

If **descriptorSetCount** is zero or this structure is not included in the `pNext` chain, then the variable lengths are considered to be zero. Otherwise, **pDescriptorCounts[i]** is the number of descriptors in the variable count descriptor binding in the corresponding descriptor set layout. If the variable
count descriptor binding in the corresponding descriptor set layout has a descriptor type of
\texttt{VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT} then \( p\text{DescriptorCounts}[i] \) specifies the binding’s capacity in bytes. If \( \text{VkDescriptorSetAllocateInfo} :: p\text{SetLayouts}[i] \) does not include a variable count descriptor binding, then \( p\text{DescriptorCounts}[i] \) is ignored.

### Valid Usage

- If \( \text{descriptorSetCount} \) is not zero, \( \text{descriptorSetCount} \) must equal \( \text{VkDescriptorSetAllocateInfo} :: \text{descriptorSetCount} \)

- If \( \text{VkDescriptorSetAllocateInfo} :: p\text{SetLayouts}[i] \) has a variable descriptor count binding, then \( p\text{DescriptorCounts}[i] \) must be less than or equal to the descriptor count specified for that binding when the descriptor set layout was created

### Valid Usage (Implicit)

- \( \text{sType} \) must be \( \text{VK_STRUCTURE_TYPE_DESCRIPTOR_SET_VARIABLE_DESCRIPTOR_COUNT_ALLOCATE_INFO} \)

- If \( \text{descriptorSetCount} \) is not 0, \( p\text{DescriptorCounts} \) must be a valid pointer to an array of \( \text{descriptorSetCount} \) \text{uint32_t} \) values

To free allocated descriptor sets, call:

\[
\text{VkResult \text{vkFreeDescriptorSets}(}
\quad \text{VkDevice}
\quad \text{VkDescriptorPool}
\quad \text{uint32_t}
\quad \text{const \text{VkDescriptorSet}*}
\text{device,}
\text{descriptorPool,}
\text{descriptorSetCount,}
\text{pDescriptorSets);}\]

- \( \text{device} \) is the logical device that owns the descriptor pool.

- \( \text{descriptorPool} \) is the descriptor pool from which the descriptor sets were allocated.

- \( \text{descriptorSetCount} \) is the number of elements in the \( p\text{DescriptorSets} \) array.

- \( p\text{DescriptorSets} \) is a pointer to an array of handles to \text{VkDescriptorSet} objects.

After calling \text{vkFreeDescriptorSets}, all descriptor sets in \( p\text{DescriptorSets} \) are invalid.
Valid Usage

- All submitted commands that refer to any element of `pDescriptorSets` must have completed execution.
- `pDescriptorSets` must be a valid pointer to an array of `descriptorSetCount` `VkDescriptorSet` handles, each element of which must either be a valid handle or `VK_NULL_HANDLE`.
- Each valid handle in `pDescriptorSets` must have been allocated from `descriptorPool`.
- `descriptorPool` must have been created with the `VK_DESCRIPTOR_POOL_CREATE_FREE_DESCRIPTOR_SET_BIT` flag.

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle.
- `descriptorPool` must be a valid `VkDescriptorPool` handle.
- `descriptorSetCount` must be greater than 0.
- `descriptorPool` must have been created, allocated, or retrieved from `device`.
- Each element of `pDescriptorSets` that is a valid handle must have been created, allocated, or retrieved from `descriptorPool`.

Host Synchronization

- Host access to `descriptorPool` must be externally synchronized.
- Host access to each member of `pDescriptorSets` must be externally synchronized.

Return Codes

**Success**

- `VK_SUCCESS`

To return all descriptor sets allocated from a given pool to the pool, rather than freeing individual descriptor sets, call:

```
VkResult vkResetDescriptorPool(
    VkDevice device,
    VkDescriptorPool descriptorPool,
    VkDescriptorPoolResetFlags flags);
```

- `device` is the logical device that owns the descriptor pool.
- `descriptorPool` is the descriptor pool to be reset.
• flags is reserved for future use.

Resetting a descriptor pool recycles all of the resources from all of the descriptor sets allocated from the descriptor pool back to the descriptor pool, and the descriptor sets are implicitly freed.

### Valid Usage

- All uses of descriptorPool (via any allocated descriptor sets) **must** have completed execution

### Valid Usage (Implicit)

- device **must** be a valid VkDevice handle
- descriptorPool **must** be a valid VkDescriptorPool handle
- flags **must** be 0
- descriptorPool **must** have been created, allocated, or retrieved from device

### Host Synchronization

- Host access to descriptorPool **must** be externally synchronized
- Host access to any VkDescriptorSet objects allocated from descriptorPool **must** be externally synchronized

### Return Codes

**Success**

- VK_SUCCESS

```c
typedef VkFlags VkDescriptorPoolResetFlags;
```

**VkDescriptorPoolResetFlags** is a bitmask type for setting a mask, but is currently reserved for future use.

### 13.2.4. Descriptor Set Updates

Once allocated, descriptor sets **can** be updated with a combination of write and copy operations. To update descriptor sets, call:
```c
void vkUpdateDescriptorSets(
    VkDevice                                    device,
    uint32_t                                    descriptorWriteCount,
    const VkWriteDescriptorSet*                 pDescriptorWrites,
    uint32_t                                    descriptorCopyCount,
    const VkCopyDescriptorSet*                  pDescriptorCopies);
```

- **device** is the logical device that updates the descriptor sets.
- **descriptorWriteCount** is the number of elements in the **pDescriptorWrites** array.
- **pDescriptorWrites** is a pointer to an array of **VkWriteDescriptorSet** structures describing the descriptor sets to write to.
- **descriptorCopyCount** is the number of elements in the **pDescriptorCopies** array.
- **pDescriptorCopies** is a pointer to an array of **VkCopyDescriptorSet** structures describing the descriptor sets to copy between.

The operations described by **pDescriptorWrites** are performed first, followed by the operations described by **pDescriptorCopies**. Within each array, the operations are performed in the order they appear in the array.

Each element in the **pDescriptorWrites** array describes an operation updating the descriptor set using descriptors for resources specified in the structure.

Each element in the **pDescriptorCopies** array is a **VkCopyDescriptorSet** structure describing an operation copying descriptors between sets.

If the **dstSet** member of any element of **pDescriptorWrites** or **pDescriptorCopies** is bound, accessed, or modified by any command that was recorded to a command buffer which is currently in the recording or executable state, and any of the descriptor bindings that are updated were not created with the **VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT** or **VK_DESCRIPTOR_BINDING_UPDATE_UNUSED_WHILE_PENDING_BIT** bits set, that command buffer becomes invalid.

**Valid Usage**

- Descriptor bindings updated by this command which were created without the **VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT** or **VK_DESCRIPTOR_BINDING_UPDATE_UNUSED_WHILE_PENDING_BIT** bits set must not be used by any command that was recorded to a command buffer which is in the pending state.
Valid Usage (Implicit)

- **device** must be a valid *VkDevice* handle
- If `descriptorWriteCount` is not 0, `pDescriptorWrites` must be a valid pointer to an array of `descriptorWriteCount` valid `VkWriteDescriptorSet` structures
- If `descriptorCopyCount` is not 0, `pDescriptorCopies` must be a valid pointer to an array of `descriptorCopyCount` valid `VkCopyDescriptorSet` structures

Host Synchronization

- Host access to `pDescriptorWrites[].dstSet` must be externally synchronized
- Host access to `pDescriptorCopies[].dstSet` must be externally synchronized

The `VkWriteDescriptorSet` structure is defined as:

```c
typedef struct VkWriteDescriptorSet {
    VkStructureType sType;
    const void* pNext;
    VkDescriptorSet dstSet;
    uint32_t dstBinding;
    uint32_t dstArrayElement;
    uint32_t descriptorCount;
    VkDescriptorType descriptorType;
    const VkDescriptorImageInfo* pImageInfo;
    const VkDescriptorBufferInfo* pBufferInfo;
    const VkBufferView* pTexelBufferView;
} VkWriteDescriptorSet;
```

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `dstSet` is the destination descriptor set to update.
- `dstBinding` is the descriptor binding within that set.
- `dstArrayElement` is the starting element in that array. If the descriptor binding identified by `dstSet` and `dstBinding` has a descriptor type of `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then `dstArrayElement` specifies the starting byte offset within the binding.
- `descriptorCount` is the number of descriptors to update (the number of elements in `pImageInfo`, `pBufferInfo`, or `pTexelBufferView` , or a value matching the `dataSize` member of a `VkWriteDescriptorSetInlineUniformBlockEXT` structure in the `pNext` chain , or a value matching the `accelerationStructureCount` of a `VkWriteDescriptorSetAccelerationStructureKHR` structure in the `pNext` chain ). If the descriptor binding identified by `dstSet` and `dstBinding` has a descriptor type of `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then `descriptorCount` specifies the number of bytes to update.
• descriptorType is a VkDescriptorType specifying the type of each descriptor in pImageInfo, pBufferInfo, or pTexelBufferView, as described below. It must be the same type as that specified in VkDescriptorSetLayoutBinding for dstSet at dstBinding. The type of the descriptor also controls which array the descriptors are taken from.

• pImageInfo is a pointer to an array of VkDescriptorImageInfo structures or is ignored, as described below.

• pBufferInfo is a pointer to an array of VkDescriptorBufferInfo structures or is ignored, as described below.

• pTexelBufferView is a pointer to an array of VkBufferView handles as described in the Buffer Views section or is ignored, as described below.

Only one of pImageInfo, pBufferInfo, or pTexelBufferView members is used according to the descriptor type specified in the descriptorType member of the containing VkWriteDescriptorSet structure, or none of them in case descriptorType is VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT, in which case the source data for the descriptor writes is taken from the VkWriteDescriptorSetInlineUniformBlockEXT structure included in the pNext chain of VkWriteDescriptorSet, or if descriptorType is VK_DESCRIPTOR_TYPE_ACCELERATION_STRUCTURE_KHR, in which case the source data for the descriptor writes is taken from the VkWriteDescriptorSetAccelerationStructureKHR structure in the pNext chain of VkWriteDescriptorSet, as specified below.

If the nullDescriptor feature is enabled, the buffer, imageView, or bufferView can be VK_NULL_HANDLE. Loads from a null descriptor return zero values and stores and atomics to a null descriptor are discarded.

If the dstBinding has fewer than descriptorCount array elements remaining starting from dstArrayElement, then the remainder will be used to update the subsequent binding - dstBinding+1 starting at array element zero. If a binding has a descriptorCount of zero, it is skipped. This behavior applies recursively, with the update affecting consecutive bindings as needed to update all descriptorCount descriptors.

Note
The same behavior applies to bindings with a descriptor type of VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT where descriptorCount specifies the number of bytes to update while dstArrayElement specifies the starting byte offset, thus in this case if the dstBinding has a smaller byte size than the sum of dstArrayElement and descriptorCount, then the remainder will be used to update the subsequent binding - dstBinding+1 starting at offset zero. This falls out as a special case of the above rule.
Valid Usage

- **dstBinding** must be less than or equal to the maximum value of **binding** of all VkDescriptorSetLayoutBinding structures specified when dstSet's descriptor set layout was created.
- **dstBinding** must be a binding with a non-zero **descriptorCount**.
- All consecutive bindings updated via a single VkWriteDescriptorSet structure, except those with a descriptorCount of zero, must have identical **descriptorType** and **stageFlags**.
- All consecutive bindings updated via a single VkWriteDescriptorSet structure, except those with a descriptorCount of zero, must all either use immutable samplers or must all not use immutable samplers.
- **descriptorType** must match the type of dstBinding within dstSet.
- **dstSet** must be a valid VkDescriptorSet handle.
- The sum of dstArrayElement and descriptorCount must be less than or equal to the number of array elements in the descriptor set binding specified by dstBinding, and all applicable consecutive bindings, as described by consecutive binding updates.
- If descriptorType is VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT, dstArrayElement must be an integer multiple of 4.
- If descriptorType is VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT, descriptorCount must be an integer multiple of 4.
- If descriptorType is VK_DESCRIPTOR_TYPE_SAMPLER, VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE, VK_DESCRIPTOR_TYPE_STORAGE_IMAGE, or VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT, pImageInfo must be a valid pointer to an array of descriptorCount valid VkDescriptorImageInfo structures.
- If descriptorType is VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER or VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER, each element of pTexelBufferView must be either a valid VkBufferView handle or VK_NULL_HANDLE.
- If descriptorType is VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER or VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER and the nullDescriptor feature is not enabled, each element of pTexelBufferView must not be VK_NULL_HANDLE.
- If descriptorType is VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER, VK_DESCRIPTOR_TYPE_STORAGE_BUFFER, VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC, or VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC, pBufferInfo must be a valid pointer to an array of descriptorCount valid VkDescriptorBufferInfo structures.
- If descriptorType is VK_DESCRIPTOR_TYPE_SAMPLER or VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, and dstSet was not allocated with a layout that included immutable samplers for dstBinding with descriptorType, the sampler member of each element of pImageInfo must be a valid VkSampler object.
- If descriptorType is VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE, VK_DESCRIPTOR_TYPE_STORAGE_IMAGE, or VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT, the imageView member of each element of pImageInfo...
must be either a valid VkImageView handle or VK_NULL_HANDLE

- If descriptorType is VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE, VK_DESCRIPTOR_TYPE_STORAGE_IMAGE, or VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT and the nullDescriptor feature is not enabled, the imageView member of each element of pImageInfo must not be VK_NULL_HANDLE

- If descriptorType is VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT, the pNext chain must include a VkWriteDescriptorSetInlineUniformBlockEXT structure whose dataSize member equals descriptorCount

- If descriptorType is VK_DESCRIPTOR_TYPE_ACCELERATION_STRUCTURE_KHR, the pNext chain must include a VkWriteDescriptorSetAccelerationStructureKHR structure whose accelerationStructureCount member equals descriptorCount

- If descriptorType is VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE, then the imageView member of each pImageInfo element must have been created without a VkSamplerYcbcrConversionInfo structure in its pNext chain

- If descriptorType is VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, and any element of pImageInfo has a imageView member that was created with a VkSamplerYcbcrConversionInfo structure in its pNext chain, then dstSet must have been allocated with a layout that included immutable samplers for dstBinding, and the corresponding immutable sampler must have been created with an identically defined VkSamplerYcbcrConversionInfo object

- If descriptorType is VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, and dstSet was allocated with a layout that included immutable samplers for dstBinding, then the imageView member of each element of pImageInfo which corresponds to an immutable sampler that enables sampler Y′C′B′C′R conversion must have been created with a VkSamplerYcbcrConversionInfo structure in its pNext chain with an identically defined VkSamplerYcbcrConversionInfo to the corresponding immutable sampler

- If descriptorType is VK_DESCRIPTOR_TYPE_STORAGE_IMAGE, for each descriptor that will be accessed via load or store operations the imageLayout member for corresponding elements of pImageInfo must be VK_IMAGE_LAYOUT_GENERAL

- If descriptorType is VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER or VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC, the offset member of each element of pBufferInfo must be a multiple of VkPhysicalDeviceLimits::minUniformBufferOffsetAlignment

- If descriptorType is VK_DESCRIPTOR_TYPE_STORAGE_BUFFER or VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC, the offset member of each element of pBufferInfo must be a multiple of VkPhysicalDeviceLimits::minStorageBufferOffsetAlignment

- If descriptorType is VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER, VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC, VK_DESCRIPTOR_TYPE_STORAGE_BUFFER, or VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC, and the buffer member of any element of pBufferInfo is the handle of a non-sparse buffer, then that buffer must be bound completely and contiguously to a single VkDeviceMemory object

- If descriptorType is VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER or VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC, the buffer member of each element of
 pBufferInfo must have been created with VK_BUFFER_USAGE_UNIFORM_BUFFER_BIT set

• If descriptorType is VK_DESCRIPTOR_TYPE_STORAGE_BUFFER or VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC, the buffer member of each element of pBufferInfo must have been created with VK_BUFFER_USAGE_STORAGE_BUFFER_BIT set

• If descriptorType is VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER or VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC, the range member of each element of pBufferInfo, or the effective range if range is VK_WHOLE_SIZE, must be less than or equal to VkPhysicalDeviceLimits::maxUniformBufferRange

• If descriptorType is VK_DESCRIPTOR_TYPE_STORAGE_BUFFER or VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC, the range member of each element of pBufferInfo, or the effective range if range is VK_WHOLE_SIZE, must be less than or equal to VkPhysicalDeviceLimits::maxStorageBufferRange

• If descriptorType is VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER, the VkBuffer that each element of pTexelBufferView was created from must have been created with VK_BUFFER_USAGE_UNIFORM_TEXEL_BUFFER_BIT set

• If descriptorType is VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER, the VkBuffer that each element of pTexelBufferView was created from must have been created with VK_BUFFER_USAGE_STORAGE_TEXEL_BUFFER_BIT set

• If descriptorType is VK_DESCRIPTOR_TYPE_STORAGE_IMAGE or VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT, the imageView member of each element of pImageInfo must have been created with the identity swizzle

• If descriptorType is VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE or VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, the imageView member of each element of pImageInfo must have been created with VK_IMAGE_USAGE_SAMPLED_BIT set

• If descriptorType is VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE or VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, the imageLayout member of each element of pImageInfo must be a member of the list given in Sampled Image or Combined Image Sampler, corresponding to its type

• If descriptorType is VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT, the imageView member of each element of pImageInfo must have been created with VK_IMAGE_USAGE_INPUT_ATTACHMENT_BIT set

• If descriptorType is VK_DESCRIPTOR_TYPE_STORAGE_IMAGE, the imageView member of each element of pImageInfo must have been created with VK_IMAGE_USAGE_STORAGE_BIT set

• All consecutive bindings updated via a single VkWriteDescriptorSet structure, except those with a descriptorCount of zero, must have identical VkDescriptorBindingFlagBits

• If descriptorType is VK_DESCRIPTOR_TYPE_SAMPLER, then dstSet must not have been allocated with a layout that included immutable samplers for dstBinding
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_WRITE_DESCRIPTOR_SET`
- Each **pNext** member of any structure (including this one) in the **pNext** chain must be either `NULL` or a pointer to a valid instance of `VkWriteDescriptorSetAccelerationStructureKHR` or `VkWriteDescriptorSetInlineUniformBlockEXT`
- The **sType** value of each struct in the **pNext** chain must be unique
- **descriptorType** must be a valid `VkDescriptorType` value
- **descriptorCount** must be greater than 0
- Both of **dstSet**, and the elements of **pTexelBufferView** that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`

The type of descriptors in a descriptor set is specified by `VkWriteDescriptorSet::descriptorType`, which must be one of the values:

```c
typedef enum VkDescriptorType {
    VK_DESCRIPTOR_TYPE_SAMPLER = 0,
    VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER = 1,
    VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE = 2,
    VK_DESCRIPTOR_TYPE_STORAGE_IMAGE = 3,
    VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER = 4,
    VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER = 5,
    VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER = 6,
    VK_DESCRIPTOR_TYPE_STORAGE_BUFFER = 7,
    VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC = 8,
    VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC = 9,
    VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT = 10,
    VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT = 1000138000,
    VK_DESCRIPTOR_TYPE_ACCELERATION_STRUCTURE_KHR = 1000165000,
    VK_DESCRIPTOR_TYPE_ACCELERATION_STRUCTURE_NV = VK_DESCRIPTOR_TYPE_ACCELERATION_STRUCTURE_KHR,
} VkDescriptorType;
```

- **VK_DESCRIPTOR_TYPE_SAMPLER** specifies a sampler descriptor.
- **VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER** specifies a combined image sampler descriptor.
- **VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE** specifies a sampled image descriptor.
- **VK_DESCRIPTOR_TYPE_STORAGE_IMAGE** specifies a storage image descriptor.
- **VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER** specifies a uniform texel buffer descriptor.
- **VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER** specifies a storage texel buffer descriptor.
- **VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER** specifies a uniform buffer descriptor.
- **VK_DESCRIPTOR_TYPE_STORAGE_BUFFER** specifies a storage buffer descriptor.
- **VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC** specifies a dynamic uniform buffer descriptor.
• **VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC** specifies a dynamic storage buffer descriptor.

• **VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT** specifies an input attachment descriptor.

• **VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT** specifies an inline uniform block.

When a descriptor set is updated via elements of `VkWriteDescriptorSet`, members of `pImageInfo`, `pBufferInfo`, and `pTexelBufferView` are only accessed by the implementation when they correspond to descriptor type being defined - otherwise they are ignored. The members accessed are as follows for each descriptor type:

• For **VK_DESCRIPTOR_TYPE_SAMPLER**, only the `sampler` member of each element of `VkWriteDescriptorSet::pImageInfo` is accessed.

• For **VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE**, **VK_DESCRIPTOR_TYPE_STORAGE_IMAGE**, or **VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT**, only the `imageView` and `imageLayout` members of each element of `VkWriteDescriptorSet::pImageInfo` are accessed.

• For **VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER**, all members of each element of `VkWriteDescriptorSet::pImageInfo` are accessed.

• For **VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER**, **VK_DESCRIPTOR_TYPE_STORAGE_BUFFER**, **VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC**, or **VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC**, all members of each element of `VkWriteDescriptorSet::pBufferInfo` are accessed.

• For **VK_DESCRIPTOR_TYPE_UNIFORM_TEXEL_BUFFER** or **VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER**, each element of `VkWriteDescriptorSet::pTexelBufferView` is accessed.

When updating descriptors with a `descriptorType` of **VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT**, none of the `pImageInfo`, `pBufferInfo`, or `pTexelBufferView` members are accessed, instead the source data of the descriptor update operation is taken from the `VkWriteDescriptorSetInLineUniformBlockEXT` structure in the `pNext` chain of `VkWriteDescriptorSet`. When updating descriptors with a `descriptorType` of **VK_DESCRIPTOR_TYPE_ACCELERATION_STRUCTURE_KHR**, none of the `pImageInfo`, `pBufferInfo`, or `pTexelBufferView` members are accessed, instead the source data of the descriptor update operation is taken from the `VkWriteDescriptorSetAccelerationStructureKHR` structure in the `pNext` chain of `VkWriteDescriptorSet`.

The `VkDescriptorBufferInfo` structure is defined as:

```c
typedef struct VkDescriptorBufferInfo {
    VkBuffer buffer;
    VkDeviceSize offset;
    VkDeviceSize range;
} VkDescriptorBufferInfo;
```

• `buffer` is **VK_NULL_HANDLE** or the buffer resource.

• `offset` is the offset in bytes from the start of `buffer`. Access to buffer memory via this descriptor uses addressing that is relative to this starting offset.

• `range` is the size in bytes that is used for this descriptor update, or **VK_WHOLE_SIZE** to use the range from `offset` to the end of the buffer.
When setting `range` to `VK_WHOLE_SIZE`, the effective range must not be larger than the maximum range for the descriptor type (`maxUniformBufferRange` or `maxStorageBufferRange`). This means that `VK_WHOLE_SIZE` is not typically useful in the common case where uniform buffer descriptors are suballocated from a buffer that is much larger than `maxUniformBufferRange`.

For `VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC` and `VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC` descriptor types, `offset` is the base offset from which the dynamic offset is applied and `range` is the static size used for all dynamic offsets.

### Valid Usage

- `offset` must be less than the size of `buffer`
- If `range` is not equal to `VK_WHOLE_SIZE`, `range` must be greater than 0
- If `range` is not equal to `VK_WHOLE_SIZE`, `range` must be less than or equal to the size of `buffer minus offset`
- If the `nullDescriptor` feature is not enabled, `buffer` must not be `VK_NULL_HANDLE`
- If `buffer` is `VK_NULL_HANDLE`, `offset` must be zero and `range` must be `VK_WHOLE_SIZE`

### Valid Usage (Implicit)

- If `buffer` is not `VK_NULL_HANDLE`, `buffer` must be a valid `VkBuffer` handle

The `VkDescriptorImageInfo` structure is defined as:

```c
typedef struct VkDescriptorImageInfo {
    VkSampler sampler;
    VkImageView imageView;
    VkImageLayout imageLayout;
} VkDescriptorImageInfo;
```

- `sampler` is a sampler handle, and is used in descriptor updates for types `VK_DESCRIPTOR_TYPE_SAMPLER` and `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER` if the binding being updated does not use immutable samplers.
- `imageView` is `VK_NULL_HANDLE` or an image view handle, and is used in descriptor updates for types `VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE`, `VK_DESCRIPTOR_TYPE_STORAGE_IMAGE`, `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`, and `VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT`.
- `imageLayout` is the layout that the image subresources accessible from `imageView` will be in at the time this descriptor is accessed. `imageLayout` is used in descriptor updates for types `VK_DESCRIPTOR_TYPE_SAMPLED_IMAGE`, `VK_DESCRIPTOR_TYPE_STORAGE_IMAGE`, `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`, and `VK_DESCRIPTOR_TYPE_INPUT_ATTACHMENT`.
Members of `VkDescriptorImageInfo` that are not used in an update (as described above) are ignored.

### Valid Usage

- **imageView** must not be 2D or 2D array image view created from a 3D image.

- If `imageView` is created from a depth/stencil image, the `aspectMask` used to create the `imageView` must include either `VK_IMAGE_ASPECT_DEPTH_BIT` or `VK_IMAGE_ASPECT_STENCIL_BIT` but not both.

- `imageLayout` must match the actual `VkImageLayout` of each subresource accessible from `imageView` at the time this descriptor is accessed as defined by the image layout matching rules.

- If `sampler` is used and the `VkFormat` of the image is a multi-planar format, the image must have been created with `VK_IMAGE_CREATE_MUTABLE_FORMAT_BIT`, and the `aspectMask` of the `imageView` must be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT` or (for three-plane formats only) `VK_IMAGE_ASPECT_PLANE_2_BIT`.

### Valid Usage (Implicit)

- Both of `imageView`, and `sampler` that are valid handles of non-ignored parameters must have been created, allocated, or retrieved from the same `VkDevice`.

If the `descriptorType` member of `VkWriteDescriptorSet` is `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then the data to write to the descriptor set is specified through a `VkWriteDescriptorSetInlineUniformBlockEXT` structure included in the `pNext` chain of `VkWriteDescriptorSet`.

The `VkWriteDescriptorSetInlineUniformBlockEXT` structure is defined as:

```c
typedef struct VkWriteDescriptorSetInlineUniformBlockEXT {
    VkStructureType    sType;
    const void*        pNext;
    uint32_t           dataSize;
    const void*        pData;
} VkWriteDescriptorSetInlineUniformBlockEXT;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `dataSize` is the number of bytes of inline uniform block data pointed to by `pData`.
- `pData` is a pointer to `dataSize` number of bytes of data to write to the inline uniform block.
Valid Usage

- `dataSize` must be an integer multiple of 4

Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_WRITE_DESCRIPTOR_SET_INLINE_UNIFORM_BLOCK_EXT`
- `pData` must be a valid pointer to an array of `dataSize` bytes
- `dataSize` must be greater than 0

The `VkWriteDescriptorSetAccelerationStructureKHR` structure is defined as:

```c
typedef struct VkWriteDescriptorSetAccelerationStructureKHR {
    VkStructureType                      sType;
    const void*                          pNext;
    uint32_t                             accelerationStructureCount;
    const VkAccelerationStructureKHR*    pAccelerationStructures;
} VkWriteDescriptorSetAccelerationStructureKHR;
```

or the equivalent

```c
typedef VkWriteDescriptorSetAccelerationStructureKHR
    VkWriteDescriptorSetAccelerationStructureNV;
```

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `accelerationStructureCount` is the number of elements in `pAccelerationStructures`.
- `pAccelerationStructures` are the acceleration structures to update.

Valid Usage

- `accelerationStructureCount` must be equal to `descriptorCount` in the extended structure
- Each acceleration structure in `pAccelerationStructures` must have been created with `VK_ACCELERATION_STRUCTURE_TYPE_TOP_LEVEL_KHR`
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_WRITE_DESCRIPTOR_SET_ACCELERATION_STRUCTURE_KHR`
- **pAccelerationStructures** must be a valid pointer to an array of `accelerationStructureCount` valid `VkAccelerationStructureKHR` handles
- **accelerationStructureCount** must be greater than 0

The `VkCopyDescriptorSet` structure is defined as:

```c
typedef struct VkCopyDescriptorSet {
    VkStructureType    sType;
    const void*        pNext;
    VkDescriptorSet    srcSet;
    uint32_t           srcBinding;
    uint32_t           srcArrayElement;
    VkDescriptorSet    dstSet;
    uint32_t           dstBinding;
    uint32_t           dstArrayElement;
    uint32_t           descriptorCount;
} VkCopyDescriptorSet;
```

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **srcSet**, **srcBinding**, and **srcArrayElement** are the source set, binding, and array element, respectively. If the descriptor binding identified by **srcSet** and **srcBinding** has a descriptor type of `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then **srcArrayElement** specifies the starting byte offset within the binding to copy from.
- **dstSet**, **dstBinding**, and **dstArrayElement** are the destination set, binding, and array element, respectively. If the descriptor binding identified by **dstSet** and **dstBinding** has a descriptor type of `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then **dstArrayElement** specifies the starting byte offset within the binding to copy to.
- **descriptorCount** is the number of descriptors to copy from the source to destination. If **descriptorCount** is greater than the number of remaining array elements in the source or destination binding, those affect consecutive bindings in a manner similar to `VkWriteDescriptorSet` above. If the descriptor binding identified by **srcSet** and **srcBinding** has a descriptor type of `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then **descriptorCount** specifies the number of bytes to copy and the remaining array elements in the source or destination binding refer to the remaining number of bytes in those.
Valid Usage

- **srcBinding** must be a valid binding within **srcSet**

- The sum of **srcArrayElement** and **descriptorCount** must be less than or equal to the number of array elements in the descriptor set binding specified by **srcBinding**, and all applicable consecutive bindings, as described by **consecutive binding updates**

- **dstBinding** must be a valid binding within **dstSet**

- The sum of **dstArrayElement** and **descriptorCount** must be less than or equal to the number of array elements in the descriptor set binding specified by **dstBinding**, and all applicable consecutive bindings, as described by **consecutive binding updates**

- The type of **dstBinding** within **dstSet** must be equal to the type of **srcBinding** within **srcSet**

- If **srcSet** is equal to **dstSet**, then the source and destination ranges of descriptors must not overlap, where the ranges may include array elements from consecutive bindings as described by **consecutive binding updates**

- If the descriptor type of the descriptor set binding specified by **srcBinding** is **VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT**, **srcArrayElement** must be an integer multiple of 4

- If the descriptor type of the descriptor set binding specified by **dstBinding** is **VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT**, **dstArrayElement** must be an integer multiple of 4

- If the descriptor type of the descriptor set binding specified by either **srcBinding** or **dstBinding** is **VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT**, **descriptorCount** must be an integer multiple of 4

- If **srcSet**’s layout was created with the **VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT** flag set, then **dstSet**’s layout must also have been created with the **VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT** flag set

- If **srcSet**’s layout was created without the **VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT** flag set, then **dstSet**’s layout must also have been created without the **VK_DESCRIPTOR_SET_LAYOUT_CREATE_UPDATE_AFTER_BIND_POOL_BIT** flag set

- If the descriptor pool from which **srcSet** was allocated was created with the **VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT** flag set, then the descriptor pool from which **dstSet** was allocated must also have been created with the **VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT** flag set

- If the descriptor pool from which **srcSet** was allocated was created without the **VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT** flag set, then the descriptor pool from which **dstSet** was allocated must also have been created without the **VK_DESCRIPTOR_POOL_CREATE_UPDATE_AFTER_BIND_BIT** flag set

- If the descriptor type of the descriptor set binding specified by **dstBinding** is **VK_DESCRIPTOR_TYPE_SAMPLER**, then **dstSet** must not have been allocated with a layout that included immutable samplers for **dstBinding**
13.2.5. Descriptor Update Templates

A descriptor update template specifies a mapping from descriptor update information in host memory to descriptors in a descriptor set. It is designed to avoid passing redundant information to the driver when frequently updating the same set of descriptors in descriptor sets.

Descriptor update template objects are represented by `VkDescriptorUpdateTemplate` handles:

```
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkDescriptorUpdateTemplate)
```

or the equivalent

```
typedef VkDescriptorUpdateTemplate VkDescriptorUpdateTemplateKHR;
```

13.2.6. Descriptor Set Updates with Templates

Updating a large `VkDescriptorSet` array can be an expensive operation since an application must specify one `VkWriteDescriptorSet` structure for each descriptor or descriptor array to update, each of which re-specifies the same state when updating the same descriptor in multiple descriptor sets. For cases when an application wishes to update the same set of descriptors in multiple descriptor sets allocated using the same `VkDescriptorSetLayout`, `vkUpdateDescriptorSetWithTemplate` can be used as a replacement for `vkUpdateDescriptorSets`.

`VkDescriptorUpdateTemplate` allows implementations to convert a set of descriptor update operations on a single descriptor set to an internal format that, in conjunction with `vkUpdateDescriptorSetWithTemplate` or `vkCmdPushDescriptorSetWithTemplateKHR`, can be more efficient compared to calling `vkUpdateDescriptorSets` or `vkCmdPushDescriptorSetKHR`. The descriptors themselves are not specified in the `VkDescriptorUpdateTemplate`, rather, offsets into an application provided pointer to host memory are specified, which are combined with a pointer passed to `vkUpdateDescriptorSetWithTemplate` or `vkCmdPushDescriptorSetWithTemplateKHR`. This allows large batches of updates to be executed without having to convert application data structures into a strictly-defined Vulkan data structure.

To create a descriptor update template, call:
VkResult vkCreateDescriptorUpdateTemplateKHR(
    VkDevice                                    device,
    const VkDescriptorUpdateTemplateCreateInfo* pCreateInfo,
    const VkAllocationCallbacks*                pAllocator,
    VkDescriptorUpdateTemplate*                 pDescriptorUpdateTemplate);

• device is the logical device that creates the descriptor update template.
• pCreateInfo is a pointer to a VkDescriptorUpdateTemplateCreateInfo structure specifying the set of descriptors to update with a single call to vkCmdPushDescriptorSetWithTemplateKHR or vkUpdateDescriptorSetWithTemplate.
• pAllocator controls host memory allocation as described in the Memory Allocation chapter.
• pDescriptorUpdateTemplate is a pointer to a VkDescriptorUpdateTemplate handle in which the resulting descriptor update template object is returned.

Valid Usage (Implicit)

• device must be a valid VkDevice handle
• pCreateInfo must be a valid pointer to a valid VkDescriptorUpdateTemplateCreateInfo structure
• If pAllocator is not NULL, pAllocator must be a valid pointer to a valid VkAllocationCallbacks structure
• pDescriptorUpdateTemplate must be a valid pointer to a VkDescriptorUpdateTemplate handle

Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_OUT_OF_HOST_MEMORY
• VK_ERROR_OUT_OF_DEVICE_MEMORY

The VkDescriptorUpdateTemplateCreateInfo structure is defined as:
typedef struct VkDescriptorUpdateTemplateCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkDescriptorUpdateTemplateCreateFlags flags;
    uint32_t descriptorUpdateEntryCount;
    const VkDescriptorUpdateTemplateEntry* pDescriptorUpdateEntries;
    VkDescriptorUpdateTemplateType templateType;
    VkDescriptorSetLayout descriptorSetLayout;
    VkPipelineBindPoint pipelineBindPoint;
    VkPipelineLayout pipelineLayout;
    uint32_t set;
} VkDescriptorUpdateTemplateCreateInfo;

or the equivalent

typedef VkDescriptorUpdateTemplateCreateInfo VkDescriptorUpdateTemplateCreateInfoKHR;

- **sType** is the type of this structure.
- **pNext** is NULL or a pointer to an extension-specific structure.
- **flags** is reserved for future use.
- **descriptorUpdateEntryCount** is the number of elements in the **pDescriptorUpdateEntries** array.
- **pDescriptorUpdateEntries** is a pointer to an array of \( \text{VkDescriptorUpdateTemplateEntry} \) structures describing the descriptors to be updated by the descriptor update template.
- **templateType** specifies the type of the descriptor update template. If set to \( \text{VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_DESCRIPTOR_SET} \) it can only be used to update descriptor sets with a fixed **descriptorSetLayout**. If set to \( \text{VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR} \) it can only be used to push descriptor sets using the provided **pipelineBindPoint**, **pipelineLayout**, and **set** number.
- **descriptorSetLayout** is the descriptor set layout the parameter update template will be used with. All descriptor sets which are going to be updated through the newly created descriptor update template **must** be created with this layout. **descriptorSetLayout** is the descriptor set layout used to build the descriptor update template. All descriptor sets which are going to be updated through the newly created descriptor update template **must** be created with a layout that matches (is the same as, or defined identically to) this layout. This parameter is ignored if **templateType** is not \( \text{VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_DESCRIPTOR_SET} \).
- **pipelineBindPoint** is a \( \text{VkPipelineBindPoint} \) indicating whether the descriptors will be used by graphics pipelines or compute pipelines. This parameter is ignored if **templateType** is not \( \text{VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR} \).
- **pipelineLayout** is a \( \text{VkPipelineLayout} \) object used to program the bindings. This parameter is ignored if **templateType** is not \( \text{VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR} \).
- **set** is the set number of the descriptor set in the pipeline layout that will be updated. This parameter is ignored if **templateType** is not \( \text{VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR} \).
**Valid Usage**

- If `templateType` is `VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_DESCRIPTOR_SET`, `descriptorSetLayout` **must** be a valid `VkDescriptorSetLayout` handle.

- If `templateType` is `VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR`, `pipelineBindPoint` **must** be a valid `VkPipelineBindPoint` value.

- If `templateType` is `VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR`, `pipelineLayout` **must** be a valid `VkPipelineLayout` handle.

- If `templateType` is `VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR`, `set` **must** be the unique set number in the pipeline layout that uses a descriptor set layout that was created with `VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR`.

**Valid Usage (Implicit)**

- `sType` **must** be `VK_STRUCTURE_TYPE_DESCRIPTOR_UPDATE_TEMPLATE_CREATE_INFO`.

- `pNext` **must** be `NULL`.

- `flags` **must** be `0`.

- `pDescriptorUpdateEntries` **must** be a valid pointer to an array of `descriptorUpdateEntryCount` valid `VkDescriptorUpdateTemplateEntry` structures.

- `templateType` **must** be a valid `VkDescriptorUpdateTemplateType` value.

- `descriptorUpdateEntryCount` **must** be greater than `0`.

- Both of `descriptorSetLayout`, and `pipelineLayout` that are valid handles of non-ignored parameters **must** have been created, allocated, or retrieved from the same `VkDevice`.

```c
typedef VkFlags VkDescriptorUpdateTemplateCreateFlags;
```

or the equivalent

```c
typedef VkDescriptorUpdateTemplateCreateFlags VkDescriptorUpdateTemplateCreateFlagsKHR;
```

`VkDescriptorUpdateTemplateCreateFlags` is a bitmask type for setting a mask, but is currently reserved for future use.

The descriptor update template type is determined by the `VkDescriptorUpdateTemplateCreateInfo::templateType` property, which takes the following values:
typedef enum VkDescriptorUpdateTemplateType {
    VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_DESCRIPTOR_SET = 0,
    VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR = 1,
    VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_DESCRIPTOR_SET_KHR = 
    VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_DESCRIPTOR_SET,
} VkDescriptorUpdateTemplateType;

or the equivalent

typedef VkDescriptorUpdateTemplateType VkDescriptorUpdateTemplateTypeKHR;

• VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_DESCRIPTOR_SET specifies that the descriptor update template will be used for descriptor set updates only.

• VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR specifies that the descriptor update template will be used for push descriptor updates only.

The VkDescriptorUpdateTemplateEntry structure is defined as:

typedef struct VkDescriptorUpdateTemplateEntry {
    uint32_t dstBinding;
    uint32_t dstArrayElement;
    uint32_t descriptorCount;
    VkDescriptorType descriptorType;
    size_t offset;
    size_t stride;
} VkDescriptorUpdateTemplateEntry;

or the equivalent

typedef VkDescriptorUpdateTemplateEntry VkDescriptorUpdateTemplateEntryKHR;

• dstBinding is the descriptor binding to update when using this descriptor update template.

• dstArrayElement is the starting element in the array belonging to dstBinding. If the descriptor binding identified by srcBinding has a descriptor type of VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT then dstArrayElement specifies the starting byte offset to update.

• descriptorCount is the number of descriptors to update. If descriptorCount is greater than the number of remaining array elements in the destination binding, those affect consecutive bindings in a manner similar to VkWriteDescriptorSet above. If the descriptor binding identified by dstBinding has a descriptor type of VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT then descriptorCount specifies the number of bytes to update and the remaining array elements in the destination binding refer to the remaining number of bytes in it.

• descriptorType is a VkDescriptorType specifying the type of the descriptor.
• **offset** is the offset in bytes of the first binding in the raw data structure.

• **stride** is the stride in bytes between two consecutive array elements of the descriptor update informations in the raw data structure. The actual pointer `ptr` for each array element `j` of update entry `i` is computed using the following formula:

\[
\text{const char } *\text{ptr} = (\text{const char }*)\text{pData} + \text{pDescriptorUpdateEntries}[i].\text{offset} + j * \text{pDescriptorUpdateEntries}[i].\text{stride}
\]

The stride is useful in case the bindings are stored in structs along with other data. If `descriptorType` is `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT` then the value of `stride` is ignored and the stride is assumed to be `1`, i.e. the descriptor update information for them is always specified as a contiguous range.

---

**Valid Usage**

- **dstBinding** must be a valid binding in the descriptor set layout implicitly specified when using a descriptor update template to update descriptors.

- **dstArrayElement** and **descriptorCount** must be less than or equal to the number of array elements in the descriptor set binding implicitly specified when using a descriptor update template to update descriptors, and all applicable consecutive bindings, as described by consecutive binding updates.

- If `descriptor type` is `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT`, **dstArrayElement** must be an integer multiple of `4`.

- If `descriptor type` is `VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT`, **descriptorCount** must be an integer multiple of `4`.

---

**Valid Usage (Implicit)**

- **descriptorType** must be a valid `VkDescriptorType` value.

To destroy a descriptor update template, call:

```c
void vkDestroyDescriptorUpdateTemplateKHR(
    VkDevice device,
    VkDescriptorUpdateTemplate descriptorUpdateTemplate,
    const VkAllocationCallbacks* pAllocator);
```

- **device** is the logical device that has been used to create the descriptor update template.

- **descriptorUpdateTemplate** is the descriptor update template to destroy.

- **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
Valid Usage

- If `VkAllocationCallbacks` were provided when `descriptorSetLayout` was created, a compatible set of callbacks **must** be provided here.

- If no `VkAllocationCallbacks` were provided when `descriptorSetLayout` was created, `pAllocator` **must** be `NULL`.

Valid Usage (Implicit)

- `device` **must** be a valid `VkDevice` handle.

- If `descriptorUpdateTemplate` is not `VK_NULL_HANDLE`, `descriptorUpdateTemplate` **must** be a valid `VkDescriptorUpdateTemplate` handle.

- If `pAllocator` is not `NULL`, `pAllocator` **must** be a valid pointer to a valid `VkAllocationCallbacks` structure.

- If `descriptorUpdateTemplate` is a valid handle, it **must** have been created, allocated, or retrieved from `device`.

Host Synchronization

- Host access to `descriptorUpdateTemplate` **must** be externally synchronized.

Once a `VkDescriptorUpdateTemplate` has been created, descriptor sets **can** be updated by calling:

```c
void vkUpdateDescriptorSetWithTemplateKHR(
    VkDevice device,              // device
    VkDescriptorSet descriptorSet, // descriptorSet
    VkDescriptorUpdateTemplate descriptorUpdateTemplate, // descriptorUpdateTemplate
    const void* pData);            // pData
```

- `device` is the logical device that updates the descriptor sets.

- `descriptorSet` is the descriptor set to update.

- `descriptorUpdateTemplate` is a `VkDescriptorUpdateTemplate` object specifying the update mapping between `pData` and the descriptor set to update.

- `pData` is a pointer to memory containing one or more `VkDescriptorImageInfo`, `VkDescriptorBufferInfo`, or `VkBufferView` structures used to write the descriptors.
Valid Usage

- **pData** must be a valid pointer to a memory containing one or more valid instances of `VkDescriptorImageInfo`, `VkDescriptorBufferInfo`, or `VkBufferView` in a layout defined by `descriptorUpdateTemplate` when it was created with `vkCreateDescriptorUpdateTemplate`.

Valid Usage (Implicit)

- **device** must be a valid `VkDevice` handle.
- **descriptorSet** must be a valid `VkDescriptorSet` handle.
- **descriptorUpdateTemplate** must be a valid `VkDescriptorUpdateTemplate` handle.
- **descriptorUpdateTemplate** must have been created, allocated, or retrieved from **device**.

Host Synchronization

- Host access to **descriptorSet** must be externally synchronized.

API example

```c
struct AppBufferView {
    VkBufferView bufferView;
    uint32_t     applicationRelatedInformation;
};

struct AppDataStructure {
    VkDescriptorImageInfo   imageInfo;       // a single image info
    VkDescriptorBufferInfo  bufferInfoArray[3]; // 3 buffer infos in an array
    AppBufferView           bufferView[2];   // An application defined structure containing a bufferView
    // ... some more application related data
};

const VkDescriptorUpdateTemplateEntry descriptorUpdateTemplateEntries[] = {
    // binding to a single image descriptor
    { 0, 0, 1, VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER, offsetof(AppDataStructure, imageInfo), 0 }, // binding
    // dstArrayElement
    // descriptorCount
    // descriptorType
    // offset
    // stride is not required if descriptorCount is 1
};
```
// binding to an array of buffer descriptors
{
    1, // binding
    0, // dstArrayElement
    3, // descriptorCount
    VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER, // descriptorType
    offsetof(AppDataStructure, bufferInfoArray), // offset
    sizeof(VkDescriptorBufferInfo) // stride, descriptor buffer infos are compact
},

// binding to an array of buffer views
{
    2, // binding
    0, // dstArrayElement
    2, // descriptorCount
    VK_DESCRIPTOR_TYPE_STORAGE_TEXEL_BUFFER, // descriptorType
    offsetof(AppDataStructure, bufferView) +
    offsetof(AppBufferView, bufferView), // offset
    sizeof(AppBufferView) // stride, bufferViews do not have to be compact
},

// create a descriptor update template for descriptor set updates
const VkDescriptorUpdateTemplateCreateInfo createInfo =
{
    VK_STRUCTURE_TYPE_DESCRIPTOR_UPDATE_TEMPLATE_CREATE_INFO, // sType
    NULL, // pNext
    3, // flags
descriptorUpdateEntryCount
    descriptorUpdateTemplateEntries, //
pDescriptorUpdateEntries
    VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_DESCRIPTOR_SET, // templateType
    myLayout, // descriptorSetLayout
    0, // pipelineBindPoint, ignored by given templateType
    0, // pipelineLayout, ignored by given templateType
    0, // set, ignored by given templateType
};

VkDescriptorUpdateTemplate myDescriptorUpdateTemplate;
myResult = vkCreateDescriptorUpdateTemplate(
    myDevice,
    &createInfo,
    NULL,
    &myDescriptorUpdateTemplate);
AppDataStructure appData;

// fill appData here or cache it in your engine
vkUpdateDescriptorSetWithTemplate(myDevice, myDescriptorSet, myDescriptorUpdateTemplate, &appData);

### 13.2.7. Descriptor Set Binding

To bind one or more descriptor sets to a command buffer, call:

```c
void vkCmdBindDescriptorSets(
    VkCommandBuffer commandBuffer,  
    VkPipelineBindPoint pipelineBindPoint,  
    VkPipelineLayout layout,  
    uint32_t firstSet,  
    uint32_t descriptorSetCount,  
    const VkDescriptorSet* pDescriptorSets,  
    uint32_t dynamicOffsetCount,  
    const uint32_t* pDynamicOffsets);
```

- **commandBuffer** is the command buffer that the descriptor sets will be bound to.
- **pipelineBindPoint** is a `VkPipelineBindPoint` indicating whether the descriptors will be used by graphics pipelines or compute pipelines. There is a separate set of bind points for each of graphics and compute, so binding one does not disturb the other.
- **layout** is a `VkPipelineLayout` object used to program the bindings.
- **firstSet** is the set number of the first descriptor set to be bound.
- **descriptorSetCount** is the number of elements in the `pDescriptorSets` array.
- **pDescriptorSets** is a pointer to an array of handles to `VkDescriptorSet` objects describing the descriptor sets to write to.
- **dynamicOffsetCount** is the number of dynamic offsets in the `pDynamicOffsets` array.
- **pDynamicOffsets** is a pointer to an array of `uint32_t` values specifying dynamic offsets.

`vkCmdBindDescriptorSets` causes the sets numbered `firstSet .. firstSet + descriptorSetCount - 1` to use the bindings stored in `pDescriptorSets[0 .. descriptorSetCount - 1]` for subsequent rendering commands (either compute or graphics, according to the `pipelineBindPoint`). Any bindings that were previously applied via these sets are no longer valid.

Once bound, a descriptor set affects rendering of subsequent graphics or compute commands in the command buffer until a different set is bound to the same set number, or else until the set is disturbed as described in [Pipeline Layout Compatibility](#).

A compatible descriptor set **must** be bound for all set numbers that any shaders in a pipeline
access, at the time that a draw or dispatch command is recorded to execute using that pipeline. However, if none of the shaders in a pipeline statically use any bindings with a particular set number, then no descriptor set need be bound for that set number, even if the pipeline layout includes a non-trivial descriptor set layout for that set number.

If any of the sets being bound include dynamic uniform or storage buffers, then pDynamicOffsets includes one element for each array element in each dynamic descriptor type binding in each set. Values are taken from pDynamicOffsets in an order such that all entries for set N come before set N+1; within a set, entries are ordered by the binding numbers in the descriptor set layouts; and within a binding array, elements are in order. dynamicOffsetCount must equal the total number of dynamic descriptors in the sets being bound.

The effective offset used for dynamic uniform and storage buffer bindings is the sum of the relative offset taken from pDynamicOffsets, and the base address of the buffer plus base offset in the descriptor set. The range of the dynamic uniform and storage buffer bindings is the buffer range as specified in the descriptor set.

Each of the pDescriptorSets must be compatible with the pipeline layout specified by layout. The layout used to program the bindings must also be compatible with the pipeline used in subsequent graphics or compute commands, as defined in the Pipeline Layout Compatibility section.

The descriptor set contents bound by a call to vkCmdBindDescriptorSets may be consumed at the following times:

• For descriptor bindings created with the VK_DESCRIPTOR_BINDING_UPDATE_AFTER_BIND_BIT bit set, the contents may be consumed when the command buffer is submitted to a queue, or during shader execution of the resulting draws and dispatches, or any time in between. Otherwise,

• during host execution of the command, or during shader execution of the resulting draws and dispatches, or any time in between.

Thus, the contents of a descriptor set binding must not be altered (overwritten by an update command, or freed) between the first point in time that it may be consumed, and when the command completes executing on the queue.

The contents of pDynamicOffsets are consumed immediately during execution of vkCmdBindDescriptorSets. Once all pending uses have completed, it is legal to update and reuse a descriptor set.
Valid Usage

- Each element of `pDescriptorSets` **must** have been allocated with a `VkDescriptorSetLayout` that matches (is the same as, or identically defined as) the `VkDescriptorSetLayout` at set \( n \) in `layout`, where \( n \) is the sum of `firstSet` and the index into `pDescriptorSets`.

- `dynamicOffsetCount` **must** be equal to the total number of dynamic descriptors in `pDescriptorSets`.

- The sum of `firstSet` and `descriptorSetCount` **must** be less than or equal to `VkPipelineLayoutCreateInfo::setLayoutCount` provided when `layout` was created.

- `pipelineBindPoint` **must** be supported by the `commandBuffer`'s parent `VkCommandPool`'s queue family.

- Each element of `pDynamicOffsets` which corresponds to a descriptor binding with type `VK_DESCRIPTOR_TYPE_UNIFORM_BUFFER_DYNAMIC` **must** be a multiple of `VkPhysicalDeviceLimits::minUniformBufferOffsetAlignment`.

- Each element of `pDynamicOffsets` which corresponds to a descriptor binding with type `VK_DESCRIPTOR_TYPE_STORAGE_BUFFER_DYNAMIC` **must** be a multiple of `VkPhysicalDeviceLimits::minStorageBufferOffsetAlignment`.

- For each dynamic uniform or storage buffer binding in `pDescriptorSets`, the sum of the effective offset, as defined above, and the range of the binding **must** be less than or equal to the size of the buffer.

Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle.

- `pipelineBindPoint` **must** be a valid `VkPipelineBindPoint` value.

- `layout` **must** be a valid `VkPipelineLayout` handle.

- `pDescriptorSets` **must** be a valid pointer to an array of `descriptorSetCount` valid `VkDescriptorSet` handles.

- If `dynamicOffsetCount` is not 0, `pDynamicOffsets` **must** be a valid pointer to an array of `dynamicOffsetCount` `uint32_t` values.

- `commandBuffer` **must** be in the recording state.

- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics, or compute operations.

- `descriptorSetCount` **must** be greater than 0.

- Each of `commandBuffer`, `layout`, and the elements of `pDescriptorSets` **must** have been created, allocated, or retrieved from the same `VkDevice`. 
Host Synchronization

- Host access to `commandBuffer` must be externally synchronized.
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized.

13.2.8. Push Descriptor Updates

In addition to allocating descriptor sets and binding them to a command buffer, an application can record descriptor updates into the command buffer.

To push descriptor updates into a command buffer, call:

```c
void vkCmdPushDescriptorSetKHR(
    VkCommandBuffer commandBuffer,
    VkPipelineBindPoint pipelineBindPoint,
    VkPipelineLayout layout,
    uint32_t set,
    uint32_t descriptorWriteCount,
    const VkWriteDescriptorSet* pDescriptorWrites);
```

- `commandBuffer` is the command buffer that the descriptors will be recorded in.
- `pipelineBindPoint` is a `VkPipelineBindPoint` indicating whether the descriptors will be used by graphics pipelines or compute pipelines. There is a separate set of push descriptor bindings for each of graphics and compute, so binding one does not disturb the other.
- `layout` is a `VkPipelineLayout` object used to program the bindings.
- `set` is the set number of the descriptor set in the pipeline layout that will be updated.
- `descriptorWriteCount` is the number of elements in the `pDescriptorWrites` array.
- `pDescriptorWrites` is a pointer to an array of `VkWriteDescriptorSet` structures describing the descriptors to be updated.

*Push descriptors* are a small bank of descriptors whose storage is internally managed by the command buffer rather than being written into a descriptor set and later bound to a command buffer. Push descriptors allow for incremental updates of descriptors without managing the lifetime of descriptor sets.
When a command buffer begins recording, all push descriptors are undefined. Push descriptors can be updated incrementally and cause shaders to use the updated descriptors for subsequent rendering commands (either compute or graphics, according to the `pipelineBindPoint`) until the descriptor is overwritten, or else until the set is disturbed as described in Pipeline Layout Compatibility. When the set is disturbed or push descriptors with a different descriptor set layout are set, all push descriptors are undefined.

Push descriptors that are statically used by a pipeline must not be undefined at the time that a draw or dispatch command is recorded to execute using that pipeline. This includes immutable sampler descriptors, which must be pushed before they are accessed by a pipeline (the immutable samplers are pushed, rather than the samplers in `pDescriptorWrites`). Push descriptors that are not statically used can remain undefined.

Push descriptors do not use dynamic offsets. Instead, the corresponding non-dynamic descriptor types can be used and the offset member of `VkDescriptorBufferInfo` can be changed each time the descriptor is written.

Each element of `pDescriptorWrites` is interpreted as in `VkWriteDescriptorSet`, except the `dstSet` member is ignored.

To push an immutable sampler, use a `VkWriteDescriptorSet` with `dstBinding` and `dstArrayElement` selecting the immutable sampler’s binding. If the descriptor type is `VK_DESCRIPTOR_TYPE_SAMPLER`, the `pImageInfo` parameter is ignored and the immutable sampler is taken from the push descriptor set layout in the pipeline layout. If the descriptor type is `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER`, the `sampler` member of the `pImageInfo` parameter is ignored and the immutable sampler is taken from the push descriptor set layout in the pipeline layout.

---

**Valid Usage**

- `pipelineBindPoint` must be supported by the `commandBuffer`’s parent `VkCommandPool`’s queue family
- `set` must be less than `VkPipelineLayoutCreateInfo::setLayoutCount` provided when `layout` was created
- `set` must be the unique set number in the pipeline layout that uses a descriptor set layout that was created with `VK_DESCRIPTOR_SET_LAYOUT_CREATE_PUSH_DESCRIPTOR_BIT_KHR`
Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `pipelineBindPoint` must be a valid `VkPipelineBindPoint` value
- `layout` must be a valid `VkPipelineLayout` handle
- `pDescriptorWrites` must be a valid pointer to an array of `descriptorWriteCount` valid `VkWriteDescriptorSet` structures
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics, or compute operations
- `descriptorWriteCount` must be greater than 0
- Both of `commandBuffer`, and `layout` must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

13.2.9. Push Descriptor Updates with Descriptor Update Templates

It is also possible to use a descriptor update template to specify the push descriptors to update. To do so, call:

```c
void vkCmdPushDescriptorSetWithTemplateKHR(
    VkCommandBuffer                             commandBuffer,
    VkDescriptorUpdateTemplate                  descriptorUpdateTemplate,
    VkPipelineLayout                            layout,
    uint32_t                                    set,
    const void*                                 pData);
```

- `commandBuffer` is the command buffer that the descriptors will be recorded in.
• descriptorUpdateTemplate is a descriptor update template defining how to interpret the descriptor information in pData.

• layout is a VkPipelineLayout object used to program the bindings. It must be compatible with the layout used to create the descriptorUpdateTemplate handle.

• set is the set number of the descriptor set in the pipeline layout that will be updated. This must be the same number used to create the descriptorUpdateTemplate handle.

• pData is a pointer to memory containing descriptors for the templated update.

Valid Usage

• The pipelineBindPoint specified during the creation of the descriptor update template must be supported by the commandBuffer's parent VkCommandPool's queue family

• pData must be a valid pointer to a memory containing one or more valid instances of VkDescriptorImageInfo, VkDescriptorBufferInfo, or VkBufferView in a layout defined by descriptorUpdateTemplate when it was created with vkCreateDescriptorUpdateTemplateKHR

Valid Usage (Implicit)

• commandBuffer must be a valid VkCommandBuffer handle

• descriptorUpdateTemplate must be a valid VkDescriptorUpdateTemplate handle

• layout must be a valid VkPipelineLayout handle

• commandBuffer must be in the recording state

• The VkCommandPool that commandBuffer was allocated from must support graphics, or compute operations

• Each of commandBuffer, descriptorUpdateTemplate, and layout must have been created, allocated, or retrieved from the same VkDevice

Host Synchronization

• Host access to commandBuffer must be externally synchronized

• Host access to the VkCommandPool that commandBuffer was allocated from must be externally synchronized
## Command Properties

</tbody>
</table>

### API example

```c
struct AppDataStructure
{
    VkDescriptorImageInfo imageInfo;  // a single image info
    // ... some more application related data
};

cont const VkDescriptorUpdateTemplateEntry descriptorUpdateTemplateEntries[] =
{
    // binding to a single image descriptor
    {0, 0, 1, VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER,
     offsetof(AppDataStructure, imageInfo), 0
    // stride is not required if descriptorCount is 1
    }
};

// create a descriptor update template for descriptor set updates
const VkDescriptorUpdateTemplateCreateInfo createInfo =
{
    VK_STRUCTURE_TYPE_DESCRIPTOR_UPDATE_TEMPLATE_CREATE_INFO,  // sType
    NULL,  // pNext
    0,  // flags
    descriptorUpdateEntryCount,  // descriptorUpdateEntryCount
    descriptorUpdateTemplateEntries,  // descriptorUpdateEntries
    VK_DESCRIPTOR_UPDATE_TEMPLATE_TYPE_PUSH_DESCRIPTORS_KHR,  // templateType
    myPipelineLayout,  // pipelineBindPoint
    0,  // pipelineLayout
    0,  // set
};

VkDescriptorUpdateTemplate myDescriptorUpdateTemplate;
```
13.2.10. Push Constant Updates

As described above in section Pipeline Layouts, the pipeline layout defines shader push constants which are updated via Vulkan commands rather than via writes to memory or copy commands.

**Note**

Push constants represent a high speed path to modify constant data in pipelines that is expected to outperform memory-backed resource updates.

The values of push constants are undefined at the start of a command buffer.

To update push constants, call:

```c
void vkCmdPushConstants(
    VkCommandBuffer                             commandBuffer,
    VkPipelineLayout                            layout,
    VkShaderStageFlags                          stageFlags,
    uint32_t                                    offset,
    uint32_t                                    size,
    const void*                                 pValues);
```

- **commandBuffer** is the command buffer in which the push constant update will be recorded.
- **layout** is the pipeline layout used to program the push constant updates.
- **stageFlags** is a bitmask of VkShaderStageFlagBits specifying the shader stages that will use the push constants in the updated range.
- **offset** is the start offset of the push constant range to update, in units of bytes.
- **size** is the size of the push constant range to update, in units of bytes.
- **pValues** is a pointer to an array of size bytes containing the new push constant values.

**Note**

As stageFlags needs to include all flags the relevant push constant ranges were created with, any flags that are not supported by the queue family that the VkCommandPool used to allocate commandBuffer was created on are ignored.
Valid Usage

- For each byte in the range specified by offset and size and for each shader stage in stageFlags, there must be a push constant range in layout that includes that byte and that stage.
- For each byte in the range specified by offset and size and for each push constant range that overlaps that byte, stageFlags must include all stages in that push constant range’s VkPushConstantRange::stageFlags.
- offset must be a multiple of 4
- size must be a multiple of 4
- offset must be less than VkPhysicalDeviceLimits::maxPushConstantsSize
- size must be less than or equal to VkPhysicalDeviceLimits::maxPushConstantsSize minus offset.

Valid Usage (Implicit)

- commandBuffer must be a valid VkCommandBuffer handle
- layout must be a valid VkPipelineLayout handle
- stageFlags must be a valid combination of VkShaderStageFlagBits values
- stageFlags must not be 0
- pValues must be a valid pointer to an array of size bytes
- commandBuffer must be in the recording state
- The VkCommandPool that commandBuffer was allocated from must support graphics, or compute operations
- size must be greater than 0
- Both of commandBuffer, and layout must have been created, allocated, or retrieved from the same VkDevice

Host Synchronization

- Host access to commandBuffer must be externally synchronized
- Host access to the VkCommandPool that commandBuffer was allocated from must be externally synchronized
13.3. Physical Storage Buffer Access

To query a 64-bit buffer device address value through which buffer memory can be accessed in a shader, call:

```cpp
VkDeviceAddress vkGetBufferDeviceAddressKHR(
    VkDevice device,
    const VkBufferDeviceAddressInfo* pInfo);
```

or the equivalent command

```cpp
VkDeviceAddress vkGetBufferDeviceAddressEXT(
    VkDevice device,
    const VkBufferDeviceAddressInfo* pInfo);
```

- `device` is the logical device that the buffer was created on.
- `pInfo` is a pointer to a `VkBufferDeviceAddressInfo` structure specifying the buffer to retrieve an address for.

The 64-bit return value is an address of the start of `pInfo->buffer`. The address range starting at this value and whose size is the size of the buffer can be used in a shader to access the memory bound to that buffer, using the `SPV_KHR_physical_storage_buffer` extension and the `PhysicalStorageBuffer` storage class. For example, this value can be stored in a uniform buffer, and the shader can read the value from the uniform buffer and use it to do a dependent read/write to this buffer. A value of zero is reserved as a “null” pointer and must not be returned as a valid buffer device address. All loads, stores, and atomics in a shader through `PhysicalStorageBuffer` pointers must access addresses in the address range of some buffer.

If the buffer was created with a non-zero value of `VkBufferOpaqueCaptureAddressCreateInfo::opaqueCaptureAddress` `VkBufferDeviceAddressCreateInfoEXT::deviceAddress` the return value will be the same address that was returned at capture time.
Valid Usage

- The `bufferDeviceAddress` or `VkPhysicalDeviceBufferDeviceAddressFeaturesEXT::bufferDeviceAddress` feature must be enabled.

- If `device` was created with multiple physical devices, then the `bufferDeviceAddressMultiDevice` or `VkPhysicalDeviceBufferDeviceAddressFeaturesEXT::bufferDeviceAddressMultiDevice` feature must be enabled.

Valid Usage ( Implicit )

- `device` must be a valid `VkDevice` handle.
- `pInfo` must be a valid pointer to a valid `VkBufferDeviceAddressInfo` structure.

The `VkBufferDeviceAddressInfo` structure is defined as:

```c
typedef struct VkBufferDeviceAddressInfo {
    VkStructureType sType;
    const void* pNext;
    VkBuffer buffer;
} VkBufferDeviceAddressInfo;
```

or the equivalent

```c
typedef VkBufferDeviceAddressInfo VkBufferDeviceAddressInfoKHR;
```

or the equivalent

```c
typedef VkBufferDeviceAddressInfo VkBufferDeviceAddressInfoEXT;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `buffer` specifies the buffer whose address is being queried.

Valid Usage

- If `buffer` is non-sparse and was not created with the `VK_BUFFER_CREATE_DEVICE_ADDRESS_CAPTURE_REPLAY_BIT` flag, then it must be bound completely and contiguously to a single `VkDeviceMemory` object.
- `buffer` must have been created with `VK_BUFFER_USAGE_SHADER_DEVICE_ADDRESS_BIT`
Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_BUFFER_DEVICE_ADDRESS_INFO
• pNext must be NULL
• buffer must be a valid VkBuffer handle

To query a 64-bit buffer opaque capture address, call:

uint64_t vkGetBufferOpaqueCaptureAddressKHR(
    VkDevice  device,
    const VkBufferDeviceAddressInfo*  pInfo);

• device is the logical device that the buffer was created on.
• pInfo is a pointer to a VkBufferDeviceAddressInfo structure specifying the buffer to retrieve an address for.

The 64-bit return value is an opaque capture address of the start of pInfo->buffer.

If the buffer was created with a non-zero value of VkBufferOpaqueCaptureAddressCreateInfo::opaqueCaptureAddress the return value must be the same address.

Valid Usage

• The bufferDeviceAddress feature must be enabled
• If device was created with multiple physical devices, then the bufferDeviceAddressMultiDevice feature must be enabled

Valid Usage (Implicit)

• device must be a valid VkDevice handle
• pInfo must be a valid pointer to a valid VkBufferDeviceAddressInfo structure
Chapter 14. Shader Interfaces

When a pipeline is created, the set of shaders specified in the corresponding `Vk*PipelineCreateInfo` structure are implicitly linked at a number of different interfaces.

- Shader Input and Output Interface
- Vertex Input Interface
- Fragment Output Interface
- Fragment Input Attachment Interface
- Shader Resource Interface

Interface definitions make use of the following SPIR-V decorations:

- `DescriptorSet` and `Binding`
- `Location`, `Component`, and `Index`
- `Flat`, `NoPerspective`, `Centroid`, and `Sample`
- `Block` and `BufferBlock`
- `InputAttachmentIndex`
- `Offset`, `ArrayStride`, and `MatrixStride`
- `BuiltIn`
- `PassthroughNV`

This specification describes valid uses for Vulkan of these decorations. Any other use of one of these decorations is invalid.

14.1. Shader Input and Output Interfaces

When multiple stages are present in a pipeline, the outputs of one stage form an interface with the inputs of the next stage. When such an interface involves a shader, shader outputs are matched against the inputs of the next stage, and shader inputs are matched against the outputs of the previous stage.

All the variables forming the shader input and output `interfaces` are listed as operands to the `OpEntryPoint` instruction and are declared with the `Input` or `Output` storage classes, respectively, in the SPIR-V module. These generally form the interfaces between consecutive shader stages, regardless of any non-shader stages between the consecutive shader stages.

There are two classes of variables that can be matched between shader stages, built-in variables and user-defined variables. Each class has a different set of matching criteria.

Output variables of a shader stage have undefined values until the shader writes to them or uses the `Initializer` operand when declaring the variable.
14.1.1. Built-in Interface Block

Shader built-in variables meeting the following requirements define the built-in interface block. They must

- be explicitly declared (there are no implicit built-ins),
- be identified with a BuiltIn decoration,
- form object types as described in the Built-in Variables section, and
- be declared in a block whose top-level members are the built-ins.

There must be no more than one built-in interface block per shader per interface.

Built-ins must not have any Location or Component decorations.

14.1.2. User-defined Variable Interface

The non-built-in variables listed by OpEntryPoint with the Input or Output storage class form the user-defined variable interface. These must have SPIR-V numerical types or, recursively, composite types of such types. By default, the components of such types have a width of 32 or 64 bits. If an implementation supports storageInputOutput16, components can also have a width of 16 bits. These variables must be identified with a Location decoration and can also be identified with a Component decoration.

14.1.3. Interface Matching

Interface matching rules only apply to built-ins when they are declared as members of the built-in interface block.

Tessellation control and mesh shader per-vertex output variables and blocks, and tessellation control, tessellation evaluation, and geometry shader per-vertex input variables and blocks are required to be declared as arrays, with each element representing input or output values for a single vertex of a multi-vertex primitive. For the purposes of interface matching, the outermost array dimension of such variables and blocks is ignored.

A user-defined output variable is considered to match an input variable in the subsequent stage if the two variables are declared with the same Location and Component decoration and match in type and decoration, except that interpolation decorations are not required to match. XfbBuffer, XfbStride, Offset, and Stream are also not required to match for the purposes of interface matching. For the purposes of interface matching, variables declared without a Component decoration are considered to have a Component decoration of zero.

Note

Matching rules for passthrough geometry shaders are slightly different and are described in the Passthrough Interface Matching section.

Variables or block members declared as structures are considered to match in type if and only if the structure members match in type, decoration, number, and declaration order. Variables or block members declared as arrays are considered to match in type only if both declarations specify
the same element type and size.

At an interface between two non-fragment shader stages, the built-in interface block must match exactly, as described above, except for per-view outputs as described in Mesh Shader Per-View Outputs. At an interface involving the fragment shader inputs, the presence or absence of any built-in output does not affect the interface matching.

At an interface between two shader stages, the user-defined variable interface must match exactly, as described above.

Any input value to a shader stage is well-defined as long as the preceding stages writes to a matching output, as described above.

Additionally, scalar and vector inputs are well-defined if there is a corresponding output satisfying all of the following conditions:

- the input and output match exactly in decoration,
- the output is a vector with the same basic type and has at least as many components as the input, and
- the common component type of the input and output is 16-bit integer or floating-point, or 32-bit integer or floating-point (64-bit component types are excluded).

In this case, the components of the input will be taken from the first components of the output, and any extra components of the output will be ignored.

14.1.4. Location Assignment

This section describes location assignments for user-defined variables and how many locations are consumed by a given user-variable type. As mentioned above, some inputs and outputs have an additional level of arrayness relative to other shader inputs and outputs. This outer array level is removed from the type before considering how many locations the type consumes.

The Location value specifies an interface slot comprised of a 32-bit four-component vector conveyed between stages. The Component specifies components within these vector locations. Only types with widths of 16, 32 or 64 are supported in shader interfaces.

Inputs and outputs of the following types consume a single interface location:

- 16-bit scalar and vector types, and
- 32-bit scalar and vector types, and
- 64-bit scalar and 2-component vector types.

64-bit three- and four-component vectors consume two consecutive locations.

If a declared input or output is an array of size $n$ and each element takes $m$ locations, it will be assigned $m \times n$ consecutive locations starting with the location specified.

If the declared input or output is an $n \times m$ 16-, 32- or 64-bit matrix, it will be assigned multiple locations starting with the location specified. The number of locations assigned for each matrix will
be the same as for an \( n \)-element array of \( m \)-component vectors.

An \texttt{OpVariable} with a structure type that is not a block must be decorated with a \texttt{Location}.

When an \texttt{OpVariable} with a structure type (either block or non-block) is decorated with a \texttt{Location}, the members in the structure type \texttt{must} not be decorated with a \texttt{Location}. The \texttt{OpVariable}'s members are assigned consecutive locations in declaration order, starting from the first member, which is assigned the location decoration from the \texttt{OpVariable}.

When a block-type \texttt{OpVariable} is declared without a \texttt{Location} decoration, each member in its structure type \texttt{must} be decorated with a \texttt{Location}. Types nested deeper than the top-level members \texttt{must} not have \texttt{Location} decorations.

The locations consumed by block and structure members are determined by applying the rules above in a depth-first traversal of the instantiated members as though the structure or block member were declared as an input or output variable of the same type.

Any two inputs listed as operands on the same \texttt{OpEntryPoint} \texttt{must} not be assigned the same location, either explicitly or implicitly. Any two outputs listed as operands on the same \texttt{OpEntryPoint} \texttt{must} not be assigned the same location, either explicitly or implicitly.

The number of input and output locations available for a shader input or output interface are limited, and dependent on the shader stage as described in \texttt{Shader Input and Output Locations}. All variables in both the \texttt{built-in interface block} and the \texttt{user-defined variable interface} count against these limits. Each effective \texttt{Location} \texttt{must} have a value less than the number of locations available for the given interface, as specified in the "Locations Available" column in \texttt{Shader Input and Output Locations}.

14.1.5. Component Assignment

The Component decoration allows the Location to be more finely specified for scalars and vectors, down to the individual components within a location that are consumed. The components within a location are 0, 1, 2, and 3. A variable or block member starting at component N will consume components N, N+1, N+2, ... up through its size. For 16-, and 32-bit types, it is invalid if this sequence of components gets larger than 3. A scalar 64-bit type will consume two of these components in sequence, and a two-component 64-bit vector type will consume all four components available within a location. A three- or four-component 64-bit vector type must not specify a Component decoration. A three-component 64-bit vector type will consume all four components of the first location and components 0 and 1 of the second location. This leaves components 2 and 3 available for other component-qualified declarations.

A scalar or two-component 64-bit data type must not specify a Component decoration of 1 or 3. A Component decoration must not be specified for any type that is not a scalar or vector.

14.2. Vertex Input Interface

When the vertex stage is present in a pipeline, the vertex shader input variables form an interface with the vertex input attributes. The vertex shader input variables are matched by the Location and Component decorations to the vertex input attributes specified in the pVertexInputState member of the VkGraphicsPipelineCreateInfo structure.

The vertex shader input variables listed by OpEntryPoint with the Input storage class form the vertex input interface. These variables must be identified with a Location decoration and can also be identified with a Component decoration.

For the purposes of interface matching: variables declared without a Component decoration are considered to have a Component decoration of zero. The number of available vertex input locations is given by the maxVertexInputAttributes member of the VkPhysicalDeviceLimits structure.

See Attribute Location and Component Assignment for details.

All vertex shader inputs declared as above must have a corresponding attribute and binding in the pipeline.

14.3. Fragment Output Interface

When the fragment stage is present in a pipeline, the fragment shader outputs form an interface with the output attachments of the current subpass. The fragment shader output variables are matched by the Location and Component decorations to the color attachments specified in the pColorAttachments array of the VkSubpassDescription structure describing the subpass that the fragment shader is executed in.

The fragment shader output variables listed by OpEntryPoint with the Output storage class form the fragment output interface. These variables must be identified with a Location decoration. They can also be identified with a Component decoration and/or an Index decoration. For the purposes of interface matching: variables declared without a Component decoration are considered to have a Component decoration of zero, and variables declared without an Index decoration are considered to
have an Index decoration of zero.

A fragment shader output variable identified with a Location decoration of i is directed to the color attachment indicated by pColorAttachments[i], after passing through the blending unit as described in Blending, if enabled. Locations are consumed as described in Location Assignment. The number of available fragment output locations is given by the maxFragmentOutputAttachments member of the VkPhysicalDeviceLimits structure.

Components of the output variables are assigned as described in Component Assignment. Output components identified as 0, 1, 2, and 3 will be directed to the R, G, B, and A inputs to the blending unit, respectively, or to the output attachment if blending is disabled. If two variables are placed within the same location, they must have the same underlying type (floating-point or integer). The input values to blending or color attachment writes are undefined for components which do not correspond to a fragment shader output.

Fragment outputs identified with an Index of zero are directed to the first input of the blending unit associated with the corresponding Location. Outputs identified with an Index of one are directed to the second input of the corresponding blending unit.

No component aliasing of output variables is allowed, that is there must not be two output variables which have the same location, component, and index, either explicitly declared or implied.

Output values written by a fragment shader must be declared with either OpTypeFloat or OpTypeInt, and a Width of 32. If storageInputOutput16 is supported, output values written by a fragment shader can be also declared with either OpTypeFloat or OpTypeInt and a Width of 16. Composites of these types are also permitted. If the color attachment has a signed or unsigned normalized fixed-point format, color values are assumed to be floating-point and are converted to fixed-point as described in Conversion from Floating-Point to Normalized Fixed-Point; If the color attachment has an integer format, color values are assumed to be integers and converted to the bit-depth of the target. Any value that cannot be represented in the attachment's format is undefined. For any other attachment format no conversion is performed. If the type of the values written by the fragment shader do not match the format of the corresponding color attachment, the resulting values are undefined for those components.

### 14.4. Fragment Input Attachment Interface

When a fragment stage is present in a pipeline, the fragment shader subpass inputs form an interface with the input attachments of the current subpass. The fragment shader subpass input variables are matched by InputAttachmentIndex decorations to the input attachments specified in the pInputAttachments array of the VkSubpassDescription structure describing the subpass that the fragment shader is executed in.

The fragment shader subpass input variables with the UniformConstant storage class and a decoration of InputAttachmentIndex that are statically used by OpEntryPoint form the fragment input attachment interface. These variables must be declared with a type of OpTypeImage, a Dim operand of SubpassData, and a Sampled operand of 2.

A subpass input variable identified with an InputAttachmentIndex decoration of i reads from the input attachment indicated by pInputAttachments[i] member of VkSubpassDescription. If the subpass
input variable is declared as an array of size N, it consumes N consecutive input attachments, starting with the index specified. There must not be more than one input variable with the same InputAttachmentIndex whether explicitly declared or implied by an array declaration. The number of available input attachment indices is given by the maxPerStageDescriptorInputAttachments member of the VkPhysicalDeviceLimits structure.

Variables identified with the InputAttachmentIndex must only be used by a fragment stage. The basic data type (floating-point, integer, unsigned integer) of the subpass input must match the basic format of the corresponding input attachment, or the values of subpass loads from these variables are undefined.

See Input Attachment for more details.

14.5. Shader Resource Interface

When a shader stage accesses buffer or image resources, as described in the Resource Descriptors section, the shader resource variables must be matched with the pipeline layout that is provided at pipeline creation time.

The set of shader resources that form the shader resource interface for a stage are the variables statically used by OpEntryPoint with the storage class of Uniform, UniformConstant, or PushConstant. For the fragment shader, this includes the fragment input attachment interface.

The shader resource interface consists of two sub-interfaces: the push constant interface and the descriptor set interface.

14.5.1. Push Constant Interface

The shader variables defined with a storage class of PushConstant that are statically used by the shader entry points for the pipeline define the push constant interface. They must be:

- typed as OpTypeStruct,
- identified with a Block decoration, and
- laid out explicitly using the Offset, ArrayStride, and MatrixStride decorations as specified in Offset and Stride Assignment.

There must be no more than one push constant block statically used per shader entry point.

Each statically used member of a push constant block must be placed at an Offset such that the entire member is entirely contained within the VkPushConstantRange for each OpEntryPoint that uses it, and the stageFlags for that range must specify the appropriate VkShaderStageFlagBits for that stage. The Offset decoration for any member of a push constant block must not cause the space required for that member to extend outside the range [0, maxPushConstantsSize).

Any member of a push constant block that is declared as an array must only be accessed with dynamically uniform indices.
14.5.2. Descriptor Set Interface

The descriptor set interface is comprised of the shader variables with the storage class of StorageBuffer, Uniform or UniformConstant (including the variables in the fragment input attachment interface) that are statically used by the shader entry points for the pipeline.

These variables must have DescriptorSet and Binding decorations specified, which are assigned and matched with the VkDescriptorsetLayout objects in the pipeline layout as described in DescriptorSet and Binding Assignment.

The Image Format of an OpTypeImage declaration must not be Unknown, for variables which are used for OpImageRead, OpImageSparseRead, or OpImageWrite operations, except under the following conditions:

- For OpImageWrite, if the shaderStorageImageWriteWithoutFormat feature is enabled and the shader module declares the StorageImageWriteWithoutFormat capability.
- For OpImageRead or OpImageSparseRead, if the shaderStorageImageReadWithoutFormat feature is enabled and the shader module declares the StorageImageReadWithoutFormat capability.
- For OpImageRead, if Dim is SubpassData (indicating a read from an input attachment).

The Image Format of an OpTypeImage declaration must not be Unknown, for variables which are used for OpAtomic* operations.

Variables identified with the Uniform storage class are used to access transparent buffer backed resources. Such variables must be:

- typed as OpTypeStruct, or an array of this type,
- identified with a Block or BufferBlock decoration, and
- laid out explicitly using the Offset, ArrayStride, and MatrixStride decorations as specified in Offset and Stride Assignment.

Variables identified with the StorageBuffer storage class are used to access transparent buffer backed resources. Such variables must be:

- typed as OpTypeStruct, or an array of this type,
- identified with a Block decoration, and
- laid out explicitly using the Offset, ArrayStride, and MatrixStride decorations as specified in Offset and Stride Assignment.

The Offset decoration for any member of a Block-decorated variable in the Uniform storage class must not cause the space required for that variable to extend outside the range [0, maxUniformBufferRange). The Offset decoration for any member of a Block-decorated variable in the StorageBuffer storage class must not cause the space required for that variable to extend outside the range [0, maxStorageBufferRange).

Variables identified with the Uniform storage class can also be used to access transparent descriptor set backed resources when the variable is assigned to a descriptor set layout binding with a descriptorType of VK_DESCRIPTOR_TYPE_INLINE_UNIFORM_BLOCK_EXT. In this case the variable must be
typed as `OpTypeStruct` and **cannot** be aggregated into arrays of that type. Further, the `Offset` decoration for any member of such a variable **must** not cause the space required for that variable to extend outside the range \([0, \text{maxInlineUniformBlockSize}]\).

Variables identified with a storage class of `UniformConstant` and a decoration of `InputAttachmentIndex` **must** be declared as described in Fragment Input Attachment Interface.

SPIR-V variables decorated with a descriptor set and binding that identify a combined image sampler descriptor **can** have a type of `OpTypeImage`, `OpTypeSampler (Sampled=1)`, or `OpTypeSampledImage`.

Arrays of any of these types **can** be indexed with *constant integral expressions*. The following features **must** be enabled and capabilities **must** be declared in order to index such arrays with dynamically uniform or non-uniform indices:

- **Storage images (except storage texel buffers and input attachments):**
  - Dynamically uniform: `shaderStorageImageArrayDynamicIndexing` and `StorageImageArrayDynamicIndexing`
  - Non-uniform: `shaderStorageImageArrayNonUniformIndexing` and `StorageImageArrayNonUniformIndexing`

- **Storage texel buffers:**
  - Dynamically uniform: `shaderStorageTexelBufferArrayDynamicIndexing` and `StorageTexelBufferArrayDynamicIndexing`
  - Non-uniform: `shaderStorageTexelBufferArrayNonUniformIndexing` and `StorageTexelBufferArrayNonUniformIndexing`

- **Input attachments:**
  - Dynamically uniform: `shaderInputAttachmentArrayDynamicIndexing` and `InputAttachmentArrayDynamicIndexing`
  - Non-uniform: `shaderInputAttachmentArrayNonUniformIndexing` and `InputAttachmentArrayNonUniformIndexing`

- **Sampled images (except uniform texel buffers), samplers and combined image samplers:**
  - Dynamically uniform: `shaderSampledImageArrayDynamicIndexing` and `SampledImageArrayDynamicIndexing`
  - Non-uniform: `shaderSampledImageArrayNonUniformIndexing` and `SampledImageArrayNonUniformIndexing`

- **Uniform texel buffers:**
  - Dynamically uniform: `shaderUniformTexelBufferArrayDynamicIndexing` and `UniformTexelBufferArrayDynamicIndexing`
  - Non-uniform: `shaderUniformTexelBufferArrayNonUniformIndexing` and `UniformTexelBufferArrayNonUniformIndexing`

- **Uniform buffers:**
  - Dynamically uniform: `shaderUniformBufferArrayDynamicIndexing` and `UniformBufferArrayDynamicIndexing`
  - Non-uniform: `shaderUniformBufferArrayNonUniformIndexing` and `UniformBufferArrayNonUniformIndexing`

- **Storage buffers:**
• Dynamically uniform: shaderStorageBufferArrayDynamicIndexing and StorageBufferArrayDynamicIndexing
• Non-uniform: shaderStorageBufferArrayNonUniformIndexing and StorageBufferArrayNonUniformIndexing

• Acceleration structures:
  • No additional capabilities needed.

If an instruction loads from or stores to a resource (including atomics and image instructions) and the resource descriptor being accessed is not dynamically uniform, then the corresponding non-uniform indexing feature must be enabled and the capability must be declared. If an instruction loads from or stores to a resource (including atomics and image instructions) and the resource descriptor being accessed is not uniform, then the corresponding dynamic indexing or non-uniform feature must be enabled and the capability must be declared.

If the combined image sampler enables sampler Y’C’C_b conversion or samples a subsampled image, it must be indexed only by constant integral expressions when aggregated into arrays in shader code, irrespective of the shaderSampledImageArrayDynamicIndexing feature.

¹ in addition to DescriptorSet and Binding

### 14.5.3. DescriptorSet and Binding Assignment

A variable decorated with a `DescriptorSet` decoration of `s` and a `Binding` decoration of `b` indicates that this variable is associated with the `VkDescriptorSetLayoutBinding` that has a `binding` equal to `b` in `pSetLayouts[s]` that was specified in `VkPipelineLayoutCreateInfo`.

`DescriptorSet` decoration values must be between zero and `maxBoundDescriptorSets` minus one, inclusive. `Binding` decoration values can be any 32-bit unsigned integer value, as described in `Descriptor Set Layout`. Each descriptor set has its own binding name space.

If the `Binding` decoration is used with an array, the entire array is assigned that binding value. The array must be a single-dimensional array and size of the array must be no larger than the number of descriptors in the binding. If the array is runtime-sized, then array elements greater than or equal to the size of that binding in the bound descriptor set must not be used. If the array is runtime-sized, the `runtimeDescriptorArray` feature must be enabled and the `RuntimeDescriptorArray` capability must be declared. The index of each element of the array is referred to as the `arrayElement`. For the purposes of interface matching and descriptor set operations, if a resource variable is not an array, it is treated as if it has an `arrayElement` of zero.

There is a limit on the number of resources of each type that can be accessed by a pipeline stage as shown in Shader Resource Limits. The “Resources Per Stage” column gives the limit on the number
each type of resource that **can** be statically used for an entry point in any given stage in a pipeline. The “Resource Types” column lists which resource types are counted against the limit. Some resource types count against multiple limits.

The pipeline layout **may** include descriptor sets and bindings which are not referenced by any variables statically used by the entry points for the shader stages in the binding’s `stageFlags`.

However, if a variable assigned to a given `DescriptorSet` and `Binding` is statically used by the entry point for a shader stage, the pipeline layout **must** contain a descriptor set layout binding in that descriptor set layout and for that binding number, and that binding’s `stageFlags` **must** include the appropriate `VkShaderStageFlagBits` for that stage. The variable **must** be of a valid resource type determined by its SPIR-V type and storage class, as defined in Shader Resource and Storage Class Correspondence. The descriptor set layout binding **must** be of a corresponding descriptor type, as defined in Shader Resource and Descriptor Type Correspondence.

---

**Note**

There are no limits on the number of shader variables that can have overlapping set and binding values in a shader; but which resources are statically used has an impact. If any shader variable identifying a resource is statically used in a shader, then the underlying descriptor bound at the declared set and binding must support the declared type in the shader when the shader executes.

If multiple shader variables are declared with the same set and binding values, and with the same underlying descriptor type, they can all be statically used within the same shader. However, accesses are not automatically synchronized, and **Aliased** decorations should be used to avoid data hazards (see section 2.18.2 Aliasing in the SPIR-V specification).

If multiple shader variables with the same set and binding values are declared in a single shader, but with different declared types, where any of those are not supported by the relevant bound descriptor, that shader can only be executed if the variables with the unsupported type are not statically used.

A noteworthy example of using multiple statically-used shader variables sharing the same descriptor set and binding values is a descriptor of type `VK_DESCRIPTOR_TYPE_COMBINED_IMAGE_SAMPLER` that has multiple corresponding shader variables in the `UniformConstant` storage class, where some could be `OpTypeImage`, some could be `OpTypeSampler` (`Sampled=1`), and some could be `OpTypeSampledImage`.

### 14.5.4. Offset and Stride Assignment

All variables with a storage class of Uniform, StorageBuffer, or PushConstant **must** be explicitly laid out using the Offset, ArrayStride, and MatrixStride decorations.

**Note**

The numeric order of Offset decorations does not need to follow member declaration order.

### Alignment Requirements

There are different alignment requirements depending on the specific resources and on the features enabled on the device.

The **scalar alignment** of the type of an OpTypeStruct member is defined recursively as follows:

- A scalar of size N has a scalar alignment of N.
- A vector or matrix type has a scalar alignment equal to that of its component type.
- An array type has a scalar alignment equal to that of its element type.
- A structure has a scalar alignment equal to the largest scalar alignment of any of its members.

The **base alignment** of the type of an OpTypeStruct member is defined recursively as follows:
• A scalar has a base alignment equal to its scalar alignment.
• A two-component vector has a base alignment equal to twice its scalar alignment.
• A three- or four-component vector has a base alignment equal to four times its scalar alignment.
• An array has a base alignment equal to the base alignment of its element type.
• A structure has a base alignment equal to the largest base alignment of any of its members.
• A row-major matrix of C columns has a base alignment equal to the base alignment of a vector of C matrix components.
• A column-major matrix has a base alignment equal to the base alignment of the matrix column type.

The extended alignment of the type of an `OpTypeStruct` member is similarly defined as follows:

• A scalar, vector or matrix type has an extended alignment equal to its base alignment.
• An array or structure type has an extended alignment equal to the largest extended alignment of any of its members, rounded up to a multiple of 16.

A member is defined to improperly straddle if either of the following are true:

• It is a vector with total size less than or equal to 16 bytes, and has `Offset` decorations placing its first byte at F and its last byte at L, where floor(F / 16) != floor(L / 16).
• It is a vector with total size greater than 16 bytes and has its `Offset` decorations placing its first byte at a non-integer multiple of 16.

**Standard Buffer Layout**

Every member of an `OpTypeStruct` with storage class of `Uniform`, `StorageBuffer`, or `PushConstant` must be aligned according to the first matching rule as follows:

1. If the `scalarBlockLayout` feature is enabled on the device then every member must be aligned according to its scalar alignment.
2. All vectors must be aligned according to their scalar alignment.
3. If the `uniformBufferStandardLayout` feature is not enabled on the device, then any member of an `OpTypeStruct` with a storage class of `Uniform` and a decoration of `Block` must be aligned according to its extended alignment.
4. Every other member must be aligned according to its base alignment.

**Note**

Even if scalar alignment is supported, it is generally more performant to use the base alignment.

The memory layout must obey the following rules:

• The `Offset` decoration of any member must be a multiple of its alignment.
• Any `ArrayStride` or `MatrixStride` decoration must be a multiple of the alignment of the array or matrix as defined above.
Unless the `scalarBlockLayout` feature is enabled on the device:

- Vectors **must** not improperly straddle, as defined above.
- The `Offset` decoration of a member **must** not place it between the end of a structure or an array and the next multiple of the alignment of that structure or array.

**Note**
The `std430 layout` in GLSL satisfies these rules for types using the base alignment. The `std140 layout` satisfies the rules for types using the extended alignment.

### 14.6. Built-In Variables

Built-in variables are accessed in shaders by declaring a variable decorated with a `BuiltIn SPIR-V` decoration. The meaning of each `BuiltIn` decoration is as follows. In the remainder of this section, the name of a built-in is used interchangeably with a term equivalent to a variable decorated with that particular built-in. Built-ins that represent integer values **can** be declared as either signed or unsigned 32-bit integers.

As mentioned above, some inputs and outputs have an additional level of arrayness relative to other shader inputs and outputs. This level of arrayness is not included in the type descriptions below, but must be included when declaring the built-in.

**BaryCoordNV**

The `BaryCoordNV` decoration **can** be used to decorate a fragment shader input variable. This variable will contain a three-component floating-point vector with barycentric weights that indicate the location of the fragment relative to the screen-space locations of vertices of its primitive, obtained using perspective interpolation.

The `BaryCoordNV` decoration **must** be used only within fragment shaders.

The variable decorated with `BaryCoordNV` **must** be declared using the `Input` storage class.

The variable decorated with `BaryCoordNV` **must** be declared as three-component vector of 32-bit floating-point values.

**BaryCoordNoPerspAMD**

The `BaryCoordNoPerspAMD` decoration **can** be used to decorate a fragment shader input variable. This variable will contain the (I,J) pair of the barycentric coordinates corresponding to the fragment evaluated using linear interpolation at the fragment’s center. The K coordinate of the barycentric coordinates **can** be derived given the identity I + J + K = 1.0.

**BaryCoordNoPerspNV**

The `BaryCoordNoPerspNV` decoration **can** be used to decorate a fragment shader input variable. This variable will contain a three-component floating-point vector with barycentric weights that indicate the location of the fragment relative to the screen-space locations of vertices of its primitive, obtained using linear interpolation.

The `BaryCoordNoPerspNV` decoration **must** be used only within fragment shaders.
The variable decorated with BaryCoordNoPerspNV must be declared using the Input storage class.

The variable decorated with BaryCoordNoPerspNV must be declared as three-component vector of 32-bit floating-point values.

**BaryCoordNoPerspCentroidAMD**

The BaryCoordNoPerspCentroidAMD decoration can be used to decorate a fragment shader input variable. This variable will contain the (I,J) pair of the barycentric coordinates corresponding to the fragment evaluated using linear interpolation at the centroid. The K coordinate of the barycentric coordinates can be derived given the identity I + J + K = 1.0.

**BaryCoordNoPerspSampleAMD**

The BaryCoordNoPerspCentroidAMD decoration can be used to decorate a fragment shader input variable. This variable will contain the (I,J) pair of the barycentric coordinates corresponding to the fragment evaluated using linear interpolation at each covered sample. The K coordinate of the barycentric coordinates can be derived given the identity I + J + K = 1.0.

**BaryCoordPullModelAMD**

The BaryCoordPullModelAMD decoration can be used to decorate a fragment shader input variable. This variable will contain (1/W, 1/I, 1/J) evaluated at the fragment center and can be used to calculate gradients and then interpolate I, J, and W at any desired sample location.

**BaryCoordSmoothAMD**

The BaryCoordSmoothAMD decoration can be used to decorate a fragment shader input variable. This variable will contain the (I,J) pair of the barycentric coordinates corresponding to the fragment evaluated using perspective interpolation at the fragment's center. The K coordinate of the barycentric coordinates can be derived given the identity I + J + K = 1.0.

**BaryCoordSmoothCentroidAMD**

The BaryCoordSmoothCentroidAMD decoration can be used to decorate a fragment shader input variable. This variable will contain the (I,J) pair of the barycentric coordinates corresponding to the fragment evaluated using perspective interpolation at the centroid. The K coordinate of the barycentric coordinates can be derived given the identity I + J + K = 1.0.

**BaryCoordSmoothSampleAMD**

The BaryCoordSmoothCentroidAMD decoration can be used to decorate a fragment shader input variable. This variable will contain the (I,J) pair of the barycentric coordinates corresponding to the fragment evaluated using perspective interpolation at each covered sample. The K coordinate of the barycentric coordinates can be derived given the identity I + J + K = 1.0.

**BaseInstance**

Decorating a variable with the BaseInstance built-in will make that variable contain the integer value corresponding to the first instance that was passed to the command that invoked the current vertex shader invocation. BaseInstance is the firstInstance parameter to a direct drawing command or the firstInstance member of a structure consumed by an indirect drawing command.

The BaseInstance decoration must be used only within vertex shaders.
The variable decorated with `BaseInstance` must be declared using the input storage class.

The variable decorated with `BaseInstance` must be declared as a scalar 32-bit integer.

**BaseVertex**

Decorating a variable with the `BaseVertex` built-in will make that variable contain the integer value corresponding to the first vertex or vertex offset that was passed to the command that invoked the current vertex shader invocation. For **non-indexed drawing commands**, this variable is the `firstVertex` parameter to a **direct drawing command** or the `firstVertex` member of the structure consumed by an **indirect drawing command**. For **indexed drawing commands**, this variable is the `vertexOffset` parameter to a **direct drawing command** or the `vertexOffset` member of the structure consumed by an **indirect drawing command**.

The `BaseVertex` decoration must be used only within vertex shaders.

The variable decorated with `BaseVertex` must be declared using the input storage class.

The variable decorated with `BaseVertex` must be declared as a scalar 32-bit integer.

**ClipDistance**

Decorating a variable with the `ClipDistance` built-in decoration will make that variable contain the mechanism for controlling user clipping. `ClipDistance` is an array such that the $i^{th}$ element of the array specifies the clip distance for plane $i$. A clip distance of 0 means the vertex is on the plane, a positive distance means the vertex is inside the clip half-space, and a negative distance means the point is outside the clip half-space.

The `ClipDistance` decoration must be used only within mesh, vertex, fragment, tessellation control, tessellation evaluation, and geometry shaders.

In mesh or vertex shaders, any variable decorated with `ClipDistance` must be declared using the **Output** storage class.

In fragment shaders, any variable decorated with `ClipDistance` must be declared using the **Input** storage class.

In tessellation control, tessellation evaluation, or geometry shaders, any variable decorated with `ClipDistance` must not be in a storage class other than `Input` or `Output`.

Any variable decorated with `ClipDistance` must be declared as an array of 32-bit floating-point values.

---

**Note**

The array variable decorated with `ClipDistance` is explicitly sized by the shader.

---

**Note**

In the last vertex processing stage, these values will be linearly interpolated across the primitive and the portion of the primitive with interpolated distances less than 0 will be considered outside the clip volume. If `ClipDistance` is then used by a fragment shader, `ClipDistance` contains these linearly interpolated values.
ClipDistancePerViewNV

Decorating a variable with the ClipDistancePerViewNV built-in decoration will make that variable contain the per-view clip distances. The per-view clip distances have the same semantics as ClipDistance.

The ClipDistancePerViewNV must be used only within mesh shaders.

Any variable decorated with ClipDistancePerViewNV must be declared using the Output storage class, and must also be decorated with the PerViewNV decoration.

Any variable decorated with ClipDistancePerViewNV must be declared as a two-dimensional array of 32-bit floating-point values.

CullDistance

Decorating a variable with the CullDistance built-in decoration will make that variable contain the mechanism for controlling user culling. If any member of this array is assigned a negative value for all vertices belonging to a primitive, then the primitive is discarded before rasterization.

The CullDistance decoration must be used only within mesh, vertex, fragment, tessellation control, tessellation evaluation, and geometry shaders.

In mesh or vertex shaders, any variable decorated with CullDistance must be declared using the Output storage class.

In fragment shaders, any variable decorated with CullDistance must be declared using the Input storage class.

In tessellation control, tessellation evaluation, or geometry shaders, any variable decorated with CullDistance must not be declared in a storage class other than input or output.

Any variable decorated with CullDistance must be declared as an array of 32-bit floating-point values.

<table>

<tr>
<td>In fragment shaders, the values of the CullDistance array are linearly interpolated across each primitive.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>If CullDistance decorates an input variable, that variable will contain the corresponding value from the CullDistance decorated output variable from the previous shader stage.</td>
</tr>
</tbody>
</table>

CullDistancePerViewNV

Decorating a variable with the CullDistancePerViewNV built-in decoration will make that variable contain the per-view cull distances. The per-view clip distances have the same semantics as CullDistance.

The CullDistancePerViewNV must be used only within mesh shaders.
Any variable decorated with `CullDistancePerViewNV` must be declared using the `Output` storage class, and **must** also be decorated with the `PerViewNV` decoration.

Any variable decorated with `CullDistancePerViewNV` must be declared as a two-dimensional array of 32-bit floating-point values.

**DeviceIndex**

The `DeviceIndex` decoration **can** be applied to a shader input which will be filled with the device index of the physical device that is executing the current shader invocation. This value will be in the range \([0, \text{max}(1, \text{physicalDeviceCount}))\), where `physicalDeviceCount` is the `physicalDeviceCount` member of `VkDeviceGroupDeviceCreateInfo`.

The `DeviceIndex` decoration **can** be used in any shader.

The variable decorated with `DeviceIndex` **must** be declared using the `Input` storage class.

The variable decorated with `DeviceIndex` **must** be declared as a scalar 32-bit integer.

**DrawIndex**

Decorating a variable with the `DrawIndex` built-in will make that variable contain the integer value corresponding to the zero-based index of the drawing command that invoked the current task, mesh, or vertex shader invocation. For **indirect drawing commands**, `DrawIndex` begins at zero and increments by one for each draw command executed. The number of draw commands is given by the `drawCount` parameter. For **direct drawing commands**, `DrawIndex` is always zero. `DrawIndex` is dynamically uniform.

The `DrawIndex` decoration **must** be used only within task, mesh or vertex shaders.

The variable decorated with `DrawIndex` **must** be declared using the input storage class.

The variable decorated with `DrawIndex` **must** be declared as a scalar 32-bit integer.

When task or mesh shaders are used, only the first active stage will have proper access to the variable, other stages will have undefined values.

**FragCoord**

Decorating a variable with the `FragCoord` built-in decoration will make that variable contain the framebuffer coordinate \((x, y, z, \frac{1}{w})\) of the fragment being processed. The \((x,y)\) coordinate \((0,0)\) is the upper left corner of the upper left pixel in the framebuffer.

When **Sample Shading** is enabled, the \(x\) and \(y\) components of `FragCoord` reflect the location of one of the samples corresponding to the shader invocation.

Otherwise, the \(x\) and \(y\) components of `FragCoord` reflect the location of the center of the fragment.

The \(z\) component of `FragCoord` is the interpolated depth value of the primitive.

The \(w\) component is the interpolated \(\frac{1}{w}\).

The `FragCoord` decoration **must** be used only within fragment shaders.
The variable decorated with `FragCoord` must be declared using the `Input` storage class.

The `Centroid` interpolation decoration is ignored, but allowed, on `FragCoord`.

The variable decorated with `FragCoord` must be declared as a four-component vector of 32-bit floating-point values.

**FragDepth**

To have a shader supply a fragment-depth value, the shader must declare the `DepthReplacing` execution mode. Such a shader's fragment-depth value will come from the variable decorated with the `FragDepth` built-in decoration.

This value will be used for any subsequent depth testing performed by the implementation or writes to the depth attachment.

The `FragDepth` decoration must be used only within fragment shaders.

The variable decorated with `FragDepth` must be declared using the `Output` storage class.

The variable decorated with `FragDepth` must be declared as a scalar 32-bit floating-point value.

**FragInvocationCountEXT**

Decorating a variable with the `FragInvocationCountEXT` built-in decoration will make that variable contain the maximum number of fragment shader invocations for the fragment, as determined by `minSampleShading`.

The `FragInvocationCountEXT` decoration must be used only within fragment shaders and the `FragmentDensityEXT` capability must be declared.

If `Sample Shading` is not enabled, `FragInvocationCountEXT` will be filled with a value of 1.

The variable decorated with `FragInvocationCountEXT` must be declared using the `Input` storage class.

The variable decorated with `FragInvocationCountEXT` must be declared as a scalar 32-bit integer.

**FragSizeEXT**

Decorating a variable with the `FragSizeEXT` built-in decoration will make that variable contain the dimensions in pixels of the area that the fragment covers for that invocation.

The `FragSizeEXT` decoration must be used only within fragment shaders and the `FragmentDensityEXT` capability must be declared.

If fragment density map is not enabled, `FragSizeEXT` will be filled with a value of (1,1).

The variable decorated with `FragSizeEXT` must be declared using the `Input` storage class.

The variable decorated with `FragSizeEXT` must be declared as a two-component vector of 32-bit integers.
FragStencilRefEXT

Decorating a variable with the `FragStencilRefEXT` built-in decoration will make that variable contain the new stencil reference value for all samples covered by the fragment. This value will be used as the stencil reference value used in stencil testing.

To write to `FragStencilRefEXT`, a shader **must** declare the `StencilRefReplacingEXT` execution mode. If a shader declares the `StencilRefReplacingEXT` execution mode and there is an execution path through the shader that does not set `FragStencilRefEXT`, then the fragment’s stencil reference value is undefined for executions of the shader that take that path.

The `FragStencilRefEXT` decoration **must** be used only within fragment shaders.

The variable decorated with `FragStencilRefEXT` **must** be declared using the `Output` storage class.

The variable decorated with `FragStencilRefEXT` **must** be declared as a scalar integer value. Only the least significant \( s \) bits of the integer value of the variable decorated with `FragStencilRefEXT` are considered for stencil testing, where \( s \) is the number of bits in the stencil framebuffer attachment, and higher order bits are discarded.

FragmentSizeNV

Decorating a variable with the `FragmentSizeNV` built-in decoration will make that variable contain the width and height of the fragment.

The `FragmentSizeNV` decoration **must** be used only within fragment shaders.

The variable decorated with `FragmentSizeNV` **must** be declared using the `Input` storage class.

The variable decorated with `FragmentSizeNV` **must** be declared as a two-component vector of 32-bit integers.

FrontFacing

Decorating a variable with the `FrontFacing` built-in decoration will make that variable contain whether the fragment is front or back facing. This variable is non-zero if the current fragment is considered to be part of a front-facing polygon primitive or of a non-polygon primitive and is zero if the fragment is considered to be part of a back-facing polygon primitive.

The `FrontFacing` decoration **must** be used only within fragment shaders.

The variable decorated with `FrontFacing` **must** be declared using the `Input` storage class.

The variable decorated with `FrontFacing` **must** be declared as a boolean.

FullyCoveredEXT

Decorating a variable with the `FullyCoveredEXT` built-in decoration will make that variable indicate whether the fragment area is fully covered by the generating primitive. This variable is non-zero if conservative rasterization is enabled and the current fragment area is fully covered by the generating primitive, and is zero if the fragment is not covered or partially covered, or conservative rasterization is disabled.

The `FullyCoveredEXT` decoration **must** be used only within fragment shaders and the
FragmentFullyCoveredEXT capability must be declared.

The variable decorated with FullyCoveredEXT must be declared using the Input storage class.

The variable decorated with FullyCoveredEXT must be declared as a boolean.

If the implementation supports VkPhysicalDeviceConservativeRasterizationPropertiesEXT::conservativeRasterizationPostDepthCoverage and the PostDepthCoverage execution mode is specified the SampleMask built-in input variable will reflect the coverage after the early per-fragment depth and stencil tests are applied. If VkPhysicalDeviceConservativeRasterizationPropertiesEXT::conservativeRasterizationPostDepthCoverage is not supported the PostDepthCoverage execution mode must not be specified.

GlobalInvocationId

Decorating a variable with the GlobalInvocationId built-in decoration will make that variable contain the location of the current invocation within the global workgroup. Each component is equal to the index of the local workgroup multiplied by the size of the local workgroup plus LocalInvocationId.

The GlobalInvocationId decoration must be used only within task, mesh, or compute shaders.

The variable decorated with GlobalInvocationId must be declared using the Input storage class.

The variable decorated with GlobalInvocationId must be declared as a three-component vector of 32-bit integers.

HelperInvocation

Decorating a variable with the HelperInvocation built-in decoration will make that variable contain whether the current invocation is a helper invocation. This variable is non-zero if the current fragment being shaded is a helper invocation and zero otherwise. A helper invocation is an invocation of the shader that is produced to satisfy internal requirements such as the generation of derivatives.

The HelperInvocation decoration must be used only within fragment shaders.

The variable decorated with HelperInvocation must be declared using the Input storage class.

The variable decorated with HelperInvocation must be declared as a boolean.

Note
It is very likely that a helper invocation will have a value of SampleMask fragment shader input value that is zero.

HitKindKHR

A variable decorated with the HitKindKHR decoration will describe the intersection that triggered the execution of the current shader. The values are determined by the intersection shader. For user-defined intersection shaders this is the value that was passed to the “Hit Kind” operand of OpReportIntersectionKHR. For triangle intersection candidates, this will be one of HitKindFrontFacingTriangleKHR or HitKindBackFacingTriangleKHR.
The `HitKindKHR` decoration **must** only be used in any-hit and closest hit shaders.

Any variable decorated with `HitKindKHR` **must** be declared using the `Input` storage class.

Any variable decorated with `HitKindKHR` **must** be declared as a scalar 32-bit integer.

**HitTNV**

A variable decorated with the `HitTNV` decoration is equivalent to a variable decorated with the `RayTmaxKHR` decoration.

The `HitTNV` decoration **must** only be used in any-hit and closest hit shaders.

Any variable decorated with `HitTNV` **must** be declared using the `Input` storage class.

Any variable decorated with `HitTNV` **must** be declared as a scalar 32-bit floating-point value.

**IncomingRayFlagsKHR**

A variable with the `IncomingRayFlagsKHR` decoration will contain the ray flags passed in to the trace call that invoked this particular shader.

The `IncomingRayFlagsKHR` decoration **must** only be used in the intersection, any-hit, closest hit, and miss shaders.

Any variable decorated with `IncomingRayFlagsKHR` **must** be declared using the `Input` storage class.

Any variable decorated with `IncomingRayFlagsKHR` **must** be declared as a scalar 32-bit integer.

**InstanceId**

Decorating a variable in an intersection, any-hit, or closest hit shader with the `InstanceId` decoration will make that variable contain the index of the instance that intersects the current ray.

The `InstanceId` decoration **must** be used only within intersection, any-hit, or closest hit shaders.

The variable decorated with `InstanceId` **must** be declared using the `Input` storage class.

The variable decorated with `InstanceId` **must** be declared as a scalar 32-bit integer.
**InvocationId**

Decorating a variable with the `InvocationId` built-in decoration will make that variable contain the index of the current shader invocation in a geometry shader, or the index of the output patch vertex in a tessellation control shader.

In a geometry shader, the index of the current shader invocation ranges from zero to the number of instances declared in the shader minus one. If the instance count of the geometry shader is one or is not specified, then `InvocationId` will be zero.

The `InvocationId` decoration **must** be used only within tessellation control and geometry shaders.

The variable decorated with `InvocationId` **must** be declared using the `Input` storage class.

The variable decorated with `InvocationId` **must** be declared as a scalar 32-bit integer.

**InvocationsPerPixelNV**

Decorating a variable with the `InvocationsPerPixelNV` built-in decoration will make that variable contain the maximum number of fragment shader invocations per pixel, as derived from the effective shading rate for the fragment. If a primitive does not fully cover a pixel, the number of fragment shader invocations for that pixel **may** be less than the value of `InvocationsPerPixelNV`. If the shading rate indicates a fragment covering multiple pixels, then `InvocationsPerPixelNV` will be one.

The `InvocationsPerPixelNV` decoration **must** be used only within fragment shaders.

The variable decorated with `InvocationsPerPixelNV` **must** be declared using the `Input` storage class.

The variable decorated with `InvocationsPerPixelNV` **must** be declared as a scalar 32-bit integer.

**InstanceIndex**

Decorating a variable in a vertex shader with the `InstanceIndex` built-in decoration will make that variable contain the index of the instance that is being processed by the current vertex shader invocation. `InstanceIndex` begins at the `firstInstance` parameter to `vkCmdDraw` or `vkCmdDrawIndexed` or at the `firstInstance` member of a structure consumed by `vkCmdDrawIndirect` or `vkCmdDrawIndexedIndirect`.

The `InstanceIndex` decoration **must** be used only within vertex shaders.

The variable decorated with `InstanceIndex` **must** be declared using the `Input` storage class.

The variable decorated with `InstanceIndex` **must** be declared as a scalar 32-bit integer.

**LaunchIDKHR**

A variable decorated with the `LaunchIDKHR` decoration will specify the index of the work item being process. One work item is generated for each of the `width` × `height` × `depth` items dispatched by a `vkCmdTraceRaysKHR` command. All shader invocations inherit the same value for variables decorated with `LaunchIDKHR`. 
The `LaunchIDKHR` decoration **must** only be used within the ray generation, intersection, any-hit, closest hit, and miss shaders.

Any variable decorated with `LaunchIDKHR` **must** be declared using the `Input` storage class.

Any variable decorated with `LaunchIDKHR` **must** be declared as a three-component vector of 32-bit integer values.

**LaunchSizeKHR**

A variable decorated with the `LaunchSizeKHR` decoration will contain the `width`, `height`, and `depth` dimensions passed to the `vkCmdTraceRaysKHR` command that initiated this shader execution. The `width` is in the first component, the `height` is in the second component, and the `depth` is in the third component.

The `LaunchSizeKHR` decoration **must** only be used within ray generation, intersection, any-hit, closest hit, and miss shaders.

Any variable decorated with `LaunchSizeKHR` **must** be declared using the `Input` storage class.

Any variable decorated with `LaunchSizeKHR` **must** be declared as a three-component vector of 32-bit integer values.

**Layer**

Decorating a variable with the `Layer` built-in decoration will make that variable contain the select layer of a multi-layer framebuffer attachment.

In a mesh, vertex, tessellation evaluation, or geometry shader, any variable decorated with `Layer` can be written with the framebuffer layer index to which the primitive produced by that shader will be directed.

The last active vertex processing stage (in pipeline order) controls the `Layer` that is used. Outputs in previous shader stages are not used, even if the last stage fails to write the `Layer`.

If the last active vertex processing stage shader entry point’s interface does not include a variable decorated with `Layer`, then the first layer is used. If a vertex processing stage shader entry point’s interface includes a variable decorated with `Layer`, it **must** write the same value to `Layer` for all output vertices of a given primitive. If the `Layer` value is less than 0 or greater than or equal to the number of layers in the framebuffer, then primitives **may** still be rasterized, fragment shaders **may** be executed, and the framebuffer values for all layers are undefined.

The `Layer` decoration **must** be used only within mesh, vertex, tessellation evaluation, geometry, and fragment shaders.

In a mesh, vertex, tessellation evaluation, or geometry shader, any variable decorated with `Layer` **must** be declared using the `Output` storage class. If such a variable is also decorated with `ViewportRelativeNV`, then the `ViewportIndex` is added to the layer that is used for rendering and that is made available in the fragment shader. If the shader writes to a variable decorated `ViewportMaskNV`, then the layer selected has a different value for each viewport a primitive is rendered to.
In a fragment shader, a variable decorated with `Layer` contains the layer index of the primitive that the fragment invocation belongs to.

In a fragment shader, any variable decorated with `Layer` must be declared using the `Input` storage class.

Any variable decorated with `Layer` must be declared as a scalar 32-bit integer.

LayerPerViewNV

Decorating a variable with the `LayerPerViewNV` built-in decoration will make that variable contain the per-view layer information. The per-view layer has the same semantics as `Layer`, for each view.

The `LayerPerViewNV` must only be used within mesh shaders.

Any variable decorated with `LayerPerViewNV` must be declared using the `Output` storage class, and must also be decorated with the `PerViewNV` decoration.

Any variable decorated with `LayerPerViewNV` must be declared as an array of scalar 32-bit integer values.

LocalInvocationId

Decorating a variable with the `LocalInvocationId` built-in decoration will make that variable contain the location of the current task, mesh, or compute shader invocation within the local workgroup. Each component ranges from zero through to the size of the workgroup in that dimension minus one.

The `LocalInvocationId` decoration must be used only within task, mesh, or compute shaders.

The variable decorated with `LocalInvocationId` must be declared using the `Input` storage class.

The variable decorated with `LocalInvocationId` must be declared as a three-component vector of 32-bit integers.

Note

If the size of the workgroup in a particular dimension is one, then the `LocalInvocationId` in that dimension will be zero. If the workgroup is effectively two-dimensional, then `LocalInvocationId.z` will be zero. If the workgroup is effectively one-dimensional, then both `LocalInvocationId.y` and `LocalInvocationId.z` will be zero.

LocalInvocationIndex

Decorating a variable with the `LocalInvocationIndex` built-in decoration will make that variable contain a one-dimensional representation of `LocalInvocationId`. This is computed as:
LocalInvocationIndex =
    LocalInvocationId.z * WorkgroupSize.x * WorkgroupSize.y +
    LocalInvocationId.y * WorkgroupSize.x +
    LocalInvocationId.x;

The **LocalInvocationIndex** decoration **must** be used only within task, mesh, or compute shaders.

The variable decorated with **LocalInvocationIndex** **must** be declared using the **Input** storage class.

The variable decorated with **LocalInvocationIndex** **must** be declared as a scalar 32-bit integer.

**MeshViewCountNV**

Decorating a variable with the **MeshViewCountNV** built-in decoration will make that variable contain the number of views processed by the current mesh or task shader invocations.

The **MeshViewCountNV** decoration **must** only be used in task and mesh shaders.

Any variable decorated with **MeshViewCountNV** **must** be declared using the **Input** storage class.

Any variable decorated with **MeshViewCountNV** **must** be declared as a scalar 32-bit integer.

**MeshViewIndicesNV**

Decorating a variable with the **MeshViewIndicesNV** built-in decoration will make that variable contain the mesh view indices. The mesh view indices is an array of values where each element holds the view number of one of the views being processed by the current mesh or task shader invocations. The array elements with indices great than or equal to **MeshViewCountNV** are undefined. If the value of **MeshViewIndicesNV**[i] is j, then any outputs decorated with **PerViewNV** will take on the value of array element i when processing primitives for view index j.

The **MeshViewIndicesNV** decoration **must** only be used in task and mesh shaders.

Any variable decorated with **MeshViewIndicesNV** **must** be declared using the **Input** storage class.

Any variable decorated with **MeshViewIndicesNV** **must** be declared as an array of scalar 32-bit integers.

**NumWorkgroups**

Decorating a variable with the **NumWorkgroups** built-in decoration will make that variable contain the number of local workgroups that are part of the dispatch that the invocation belongs to. Each component is equal to the values of the workgroup count parameters passed into the dispatch commands.

The **NumWorkgroups** decoration **must** be used only within compute shaders.

The variable decorated with **NumWorkgroups** **must** be declared using the **Input** storage class.

The variable decorated with **NumWorkgroups** **must** be declared as a three-component vector of 32-bit integers.
ObjectRayDirectionKHR

A variable decorated with the ObjectRayDirectionKHR decoration will specify the direction of the ray being processed, in object space.

The ObjectRayDirectionKHR decoration must only be used within intersection, any-hit, and closest hit shaders.

Any variable decorated with ObjectRayDirectionKHR must be declared using the Input storage class.

Any variable decorated with ObjectRayDirectionKHR must be declared as a three-component vector of 32-bit floating-point values.

ObjectRayOriginKHR

A variable decorated with the ObjectRayOriginKHR decoration will specify the origin of the ray being processed, in object space.

The ObjectRayOriginKHR decoration must only be used within intersection, any-hit, and closest hit shaders.

Any variable decorated with ObjectRayOriginKHR must be declared using the Input storage class.

Any variable decorated with ObjectRayOriginKHR must be declared as a three-component vector of 32-bit floating-point values.

ObjectToWorldKHR

A variable decorated with the ObjectToWorldKHR decoration will contain the current object-to-world transformation matrix, which is determined by the instance of the current intersection.

The ObjectToWorldKHR decoration must only be used within intersection, any-hit, and closest hit shaders.

Any variable decorated with ObjectToWorldKHR must be declared using the Input storage class.

Any variable decorated with ObjectToWorldKHR must be declared as a matrix with four columns of three-component vectors of 32-bit floating-point values.

PatchVertices

Decorating a variable with the PatchVertices built-in decoration will make that variable contain the number of vertices in the input patch being processed by the shader. A single tessellation control or tessellation evaluation shader can read patches of differing sizes, so the value of the PatchVertices variable may differ between patches.

The PatchVertices decoration must be used only within tessellation control and tessellation evaluation shaders.

The variable decorated with PatchVertices must be declared using the Input storage class.

The variable decorated with PatchVertices must be declared as a scalar 32-bit integer.
PointCoord

Decorating a variable with the `PointCoord` built-in decoration will make that variable contain the coordinate of the current fragment within the point being rasterized, normalized to the size of the point with origin in the upper left corner of the point, as described in Basic Point Rasterization. If the primitive the fragment shader invocation belongs to is not a point, then the variable decorated with `PointCoord` contains an undefined value.

The `PointCoord` decoration must be used only within fragment shaders.

The variable decorated with `PointCoord` must be declared using the `Input` storage class.

The variable decorated with `PointCoord` must be declared as two-component vector of 32-bit floating-point values.

Note

Depending on how the point is rasterized, `PointCoord` may never reach (0,0) or (1,1).

PointSize

Decorating a variable with the `PointSize` built-in decoration will make that variable contain the size of point primitives. The value written to the variable decorated with `PointSize` by the last vertex processing stage in the pipeline is used as the framebuffer-space size of points produced by rasterization.

The `PointSize` decoration must be used only within mesh, vertex, tessellation control, tessellation evaluation, and geometry shaders.

In a mesh or vertex shader, any variable decorated with `PointSize` must be declared using the `Output` storage class.

In a tessellation control, tessellation evaluation, or geometry shader, any variable decorated with `PointSize` must be declared using either the `Input` or `Output` storage class.

Any variable decorated with `PointSize` must be declared as a scalar 32-bit floating-point value.

Note

When `PointSize` decorates a variable in the `Input` storage class, it contains the data written to the output variable decorated with `PointSize` from the previous shader stage.

Position

Decorating a variable with the `Position` built-in decoration will make that variable contain the position of the current vertex. In the last vertex processing stage, the value of the variable decorated with `Position` is used in subsequent primitive assembly, clipping, and rasterization operations.

The `Position` decoration must be used only within mesh, vertex, tessellation control, tessellation evaluation, and geometry shaders.
In a mesh or vertex shader, any variable decorated with `Position` must be declared using the `Output` storage class.

In a tessellation control, tessellation evaluation, or geometry shader, any variable decorated with `Position` must not be declared in a storage class other than `Input` or `Output`.

Any variable decorated with `Position` must be declared as a four-component vector of 32-bit floating-point values.

**Note**
When `Position` decorates a variable in the `Input` storage class, it contains the data written to the output variable decorated with `Position` from the previous shader stage.

**PositionPerViewNV**

Decorating a variable with the `PositionPerViewNV` built-in decoration will make that variable contain the position of the current vertex, for each view.

The `PositionPerViewNV` decoration must be used only within mesh, vertex, tessellation control, tessellation evaluation, and geometry shaders.

In a vertex shader, any variable decorated with `PositionPerViewNV` must be declared using the `Output` storage class.

In a tessellation control, tessellation evaluation, or geometry shader, any variable decorated with `PositionPerViewNV` must not be declared in a storage class other than input or output.

Any variable decorated with `PositionPerViewNV` must be declared as an array of four-component vector of 32-bit floating-point values with at least as many elements as the maximum view in the subpass's view mask plus one. The array must be indexed by a constant or specialization constant.

Elements of the array correspond to views in a multiview subpass, and those elements corresponding to views in the view mask of the subpass the shader is compiled against will be used as the position value for those views. For the final vertex processing stage in the pipeline, values written to an output variable decorated with `PositionPerViewNV` are used in subsequent primitive assembly, clipping, and rasterization operations, as with `Position`. `PositionPerViewNV` output in an earlier vertex processing stage is available as an input in the subsequent vertex processing stage.

If a shader is compiled against a subpass that has the `VK_SUBPASS_DESCRIPTION_PER_VIEW_POSITION_X_ONLY_BIT_NVX` bit set, then the position values for each view must not differ in any component other than the X component. If the values do differ, one will be chosen in an implementation-dependent manner.

**PrimitiveCountNV**

Decorating a variable with the `PrimitiveCountNV` decoration will make that variable contain the primitive count. The primitive count specifies the number of primitives in the output mesh produced by the mesh shader that will be processed by subsequent pipeline stages.
The `PrimitiveCountNV` decoration **must** only be used in mesh shaders.

Any variable decorated with `PrimitiveCountNV` **must** be declared using the `Output` storage class.

Any variable decorated with `PrimitiveCountNV` **must** be declared as a scalar 32-bit integer.

**PrimitiveId**

Decorating a variable with the `PrimitiveId` built-in decoration will make that variable contain the index of the current primitive.

The index of the first primitive generated by a drawing command is zero, and the index is incremented after every individual point, line, or triangle primitive is processed.

For triangles drawn as points or line segments (see **Polygon Mode**), the primitive index is incremented only once, even if multiple points or lines are eventually drawn.

Variables decorated with `PrimitiveId` are reset to zero between each instance drawn.

Restarting a primitive topology using primitive restart has no effect on the value of variables decorated with `PrimitiveId`.

In tessellation control and tessellation evaluation shaders, it will contain the index of the patch within the current set of rendering primitives that correspond to the shader invocation.

In a geometry shader, it will contain the number of primitives presented as input to the shader since the current set of rendering primitives was started.

In a fragment shader, it will contain the primitive index written by the geometry shader if a geometry shader is present, or with the value that would have been presented as input to the geometry shader had it been present.

In an intersection, any-hit, or closest hit shader, it will contain the index within the geometry of the triangle or bounding box being processed.

If a geometry shader is present and the fragment shader reads from an input variable decorated with `PrimitiveId`, then the geometry shader **must** write to an output variable decorated with `PrimitiveId` in all execution paths.

If a mesh shader is present and the fragment shader reads from an input variable decorated with `PrimitiveId`, then the mesh shader **must** write to the output variables decorated with `PrimitiveId` in all execution paths.

The `PrimitiveId` decoration **must** be used only within mesh, intersection, any-hit, closest hit, fragment, tessellation control, tessellation evaluation, and geometry shaders.

In an intersection, any-hit, closest hit, tessellation control, or tessellation evaluation shader, any variable decorated with `PrimitiveId` **must** be declared using the `Input` storage class.

In a geometry shader, any variable decorated with `PrimitiveId` **must** be declared using either the `Input` or `Output` storage class.
In a mesh shader, any variable decorated with `PrimitiveId` must be declared using the `Output` storage class.

In a fragment shader, any variable decorated with `PrimitiveId` must be declared using the `Input` storage class, and either the `Geometry` or `Tessellation` capability must also be declared.

Any variable decorated with `PrimitiveId` must be declared as a scalar 32-bit integer.

**Note**

When the `PrimitiveId` decoration is applied to an output variable in the mesh shader or geometry shader, the resulting value is seen through the `PrimitiveId` decorated input variable in the fragment shader.

**PrimitiveIndicesNV**

Decorating a variable with the `PrimitiveIndicesNV` decoration will make that variable contain the output array of vertex index values. Depending on the output primitive type declared using the execution mode, the indices are split into groups of one (`OutputPoints`), two (`OutputLinesNV`), or three (`OutputTriangles`) indices and each group generates a primitive.

All index values must be in the range \([0, \text{N}-1]\), where N is the value specified by the `OutputVertices` execution mode.

The `PrimitiveIndicesNV` decoration must only be used in mesh shaders.

Any variable decorated with `PrimitiveIndicesNV` must be declared using the `Output` storage class.

Any variable decorated with `PrimitiveIndicesNV` must be declared as an array of scalar 32-bit integers. The array must be sized according to the primitive type and `OutputPrimitivesNV` execution modes, where the size is:

- the value specified by `OutputPrimitivesNV` if the execution mode is `OutputPoints`,
- two times the value specified by `OutputPrimitivesNV` if the execution mode is `OutputLinesNV`, or
- three times the value specified by `OutputPrimitivesNV` if the execution mode is `OutputTrianglesNV`.

**RayGeometryIndexKHR**

A variable decorated with the `RayGeometryIndexKHR` decoration will contain the generated index for the acceleration structure geometry currently being shaded.

The `RayGeometryIndexKHR` decoration must only be used within intersection, any-hit, and closest hit shaders.

Any variable decorated with `RayGeometryIndexKHR` must be declared using the `Input` storage class.

Any variable decorated with `RayGeometryIndexKHR` must be declared as a scalar 32-bit integer value.
RayTmaxKHR

A variable decorated with the RayTmaxKHR decoration will contain the parametric $t_{\text{max}}$ values of the ray being processed. The values are independent of the space in which the ray and origin exist.

The $t_{\text{max}}$ value changes throughout the lifetime of the ray query that produced the intersection. In the closest hit shader, the value reflects the closest distance to the intersected primitive. In the any-hit shader, it reflects the distance to the primitive currently being intersected. In the intersection shader, it reflects the distance to the closest primitive intersected so far. The value can change in the intersection shader after calling OpReportIntersectionKHR if the corresponding any-hit shader does not ignore the intersection. In a miss shader, the value is identical to the parameter passed into OpTraceRayKHR.

The RayTmaxKHR decoration must only be used with the intersection, any-hit, closest hit, and miss shaders.

Any variable decorated with RayTmaxKHR must be declared with the Input storage class.

Any variable decorated with RayTmaxKHR must be declared as a scalar 32-bit floating-point value.

RayTminKHR

A variable decorated with the RayTminKHR decoration will contain the parametric $t_{\text{min}}$ values of the ray being processed. The values are independent of the space in which the ray and origin exist.

The $t_{\text{min}}$ value remains constant for the duration of the ray query.

The RayTminKHR decoration must only be used with the intersection, any-hit, closest hit, and miss shaders.

Any variable decorated with RayTminKHR must be declared with the Input storage class.

Any variable decorated with RayTminKHR must be declared as a scalar 32-bit floating-point value.

SampleId

Decorating a variable with the SampleId built-in decoration will make that variable contain the coverage index for the current fragment shader invocation. SampleId ranges from zero to the number of samples in the framebuffer minus one. If a fragment shader entry point's interface includes an input variable decorated with SampleId, Sample Shading is considered enabled with a minSampleShading value of 1.0.

The SampleId decoration must be used only within fragment shaders.

The variable decorated with SampleId must be declared using the Input storage class.

The variable decorated with SampleId must be declared as a scalar 32-bit integer.

SampleMask

Decorating a variable with the SampleMask built-in decoration will make any variable contain the coverage mask for the current fragment shader invocation.
A variable in the Input storage class decorated with SampleMask will contain a bitmask of the set of samples covered by the primitive generating the fragment during rasterization. It has a sample bit set if and only if the sample is considered covered for this fragment shader invocation. SampleMask[] is an array of integers. Bits are mapped to samples in a manner where bit B of mask M (SampleMask[M]) corresponds to sample $32 \times M + B$.

When state specifies multiple fragment shader invocations for a given fragment, the sample mask for any single fragment shader invocation specifies the subset of the covered samples for the fragment that correspond to the invocation. In this case, the bit corresponding to each covered sample will be set in exactly one fragment shader invocation.

If the PostDepthCoverage execution mode is specified, the sample is considered covered if and only if the sample is covered by the primitive, and the sample is still covered after depth testing. Otherwise the sample is considered covered if the sample is covered by the primitive, regardless of the result of the fragment tests.

A variable in the Output storage class decorated with SampleMask is an array of integers forming a bit array in a manner similar an input variable decorated with SampleMask, but where each bit represents coverage as computed by the shader. Modifying the sample mask by writing zero to a bit of SampleMask causes the sample to be considered uncovered. If this variable is also decorated with OverrideCoverageNV, the fragment coverage is replaced with the sample mask bits set in the shader otherwise the fragment coverage is ANDed with the bits of the sample mask. If the fragment shader is being evaluated at any frequency other than per-fragment, bits of the sample mask not corresponding to the current fragment shader invocation are ignored. This array must be sized in the fragment shader either implicitly or explicitly, to be no larger than the implementation-dependent maximum sample-mask (as an array of 32-bit elements), determined by the maximum number of samples. If a fragment shader entry point's interface includes an output variable decorated with SampleMask, the sample mask will be undefined for any array elements of any fragment shader invocations that fail to assign a value. If a fragment shader entry point's interface does not include an output variable decorated with SampleMask, the sample mask has no effect on the processing of a fragment.

The SampleMask decoration must be used only within fragment shaders.

Any variable decorated with SampleMask must be declared using either the Input or Output storage class.

Any variable decorated with SampleMask must be declared as an array of 32-bit integers.

SamplePosition

Decorating a variable with the SamplePosition built-in decoration will make that variable contain the sub-pixel position of the sample being shaded. The top left of the pixel is considered to be at coordinate (0,0) and the bottom right of the pixel is considered to be at coordinate (1,1).

If the render pass has a fragment density map attachment, the variable will instead contain the sub-fragment position of the sample being shaded. The top left of the fragment is considered to be at coordinate (0,0) and the bottom right of the fragment is considered to be at coordinate (1,1) for any fragment area.

If a fragment shader entry point's interface includes an input variable decorated with
SamplePosition, Sample Shading is considered enabled with a minSampleShading value of 1.0.

The SamplePosition decoration must be used only within fragment shaders.

The variable decorated with SamplePosition must be declared using the Input storage class. If the current pipeline uses custom sample locations the value of any variable decorated with the SamplePosition built-in decoration is undefined.

The variable decorated with SamplePosition must be declared as a two-component vector of 32-bit floating-point values.

**SMCountNV**

Decorating a variable with the SMCountNV built-in decoration will make that variable contain the number of SMs on the device.

The variable decorated with SMCountNV must be declared using the Input storage class.

The variable decorated with SMCountNV must be declared as a scalar 32-bit integer value.

**SMIDNV**

Decorating a variable with the SMIDNV built-in decoration will make that variable contain the ID of the SM on which the current shader invocation is running. This variable is in the range [0, SMCountNV-1].

The variable decorated with SMIDNV must be declared using the Input storage class.

The variable decorated with SMIDNV must be declared as a scalar 32-bit integer value.

**SubgroupEqMask**

Decorating a variable with the SubgroupEqMask builtin decoration will make that variable contain the subgroup mask of the current subgroup invocation. The bit corresponding to the SubgroupLocalInvocationId is set in the variable decorated with SubgroupEqMask. All other bits are set to zero.

The variable decorated with SubgroupEqMask must be declared using the Input storage class.

The variable decorated with SubgroupEqMask must be declared as a four-component vector of 32-bit integer values.

SubgroupEqMaskKHR is an alias of SubgroupEqMask.

**SubgroupGeMask**

Decorating a variable with the SubgroupGeMask builtin decoration will make that variable contain the subgroup mask of the current subgroup invocation. The bits corresponding to the invocations greater than or equal to SubgroupLocalInvocationId through SubgroupSize-1 are set in the variable decorated with SubgroupGeMask. All other bits are set to zero.

The variable decorated with SubgroupGeMask must be declared using the Input storage class.

The variable decorated with SubgroupGeMask must be declared as a four-component vector of 32-bit integer values.
SubgroupGeMaskKHR is an alias of SubgroupGeMask.

**SubgroupGtMask**

Decorating a variable with the SubgroupGtMask builtin decoration will make that variable contain the subgroup mask of the current subgroup invocation. The bits corresponding to the invocations greater than SubgroupLocalInvocationId through SubgroupSize-1 are set in the variable decorated with SubgroupGtMask. All other bits are set to zero.

The variable decorated with **SubgroupGtMask** must be declared using the Input storage class.

The variable decorated with **SubgroupGtMask** must be declared as a four-component vector of 32-bit integer values.

SubgroupGtMaskKHR is an alias of SubgroupGtMask.

**SubgroupLeMask**

Decorating a variable with the SubgroupLeMask builtin decoration will make that variable contain the subgroup mask of the current subgroup invocation. The bits corresponding to the invocations less than or equal to SubgroupLocalInvocationId are set in the variable decorated with SubgroupLeMask. All other bits are set to zero.

The variable decorated with **SubgroupLeMask** must be declared using the Input storage class.

The variable decorated with **SubgroupLeMask** must be declared as a four-component vector of 32-bit integer values.

SubgroupLeMaskKHR is an alias of SubgroupLeMask.

**SubgroupLtMask**

Decorating a variable with the SubgroupLtMask builtin decoration will make that variable contain the subgroup mask of the current subgroup invocation. The bits corresponding to the invocations less than SubgroupLocalInvocationId are set in the variable decorated with SubgroupLtMask. All other bits are set to zero.

The variable decorated with **SubgroupLtMask** must be declared using the Input storage class.

The variable decorated with **SubgroupLtMask** must be declared as a four-component vector of 32-bit integer values.

SubgroupLtMaskKHR is an alias of SubgroupLtMask.

**SubgroupLocalInvocationId**

Decorating a variable with the SubgroupLocalInvocationId builtin decoration will make that variable contain the index of the invocation within the subgroup. This variable is in range [0,SubgroupSize-1].

The variable decorated with **SubgroupLocalInvocationId** must be declared using the Input storage class.

The variable decorated with **SubgroupLocalInvocationId** must be declared as a scalar 32-bit
integer.

**Note**

There is no direct relationship between `SubgroupLocalInvocationId` and `LocalInvocationId` or `LocalInvocationIndex`. If the pipeline was created with `VK_PIPELINE_SHADER_STAGE_CREATE_REQUIRE_FULL_SUBGROUPS_BIT_EXT`, applications can compute their own local invocation index to serve the same purpose:

\[ \text{index} = \text{SubgroupLocalInvocationId} + \text{SubgroupId} \times \text{SubgroupSize} \]

If full subgroups are not enabled, some subgroups may be dispatched with inactive invocations that don't correspond to a local workgroup invocation, making the value of index unreliable.

**SubgroupSize**

Decorating a variable with the `SubgroupSize` builtin decoration will make that variable contain the implementation-dependent **number of invocations in a subgroup**. This value **must** be a power-of-two integer.

If the pipeline was created with the `VK_PIPELINE_SHADER_STAGE_CREATE_ALLOW_VARYING_SUBGROUP_SIZE_BIT_EXT` flag set, the `SubgroupSize` decorated variable will contain the subgroup size for each subgroup that gets dispatched. This value **must** be between `minSubgroupSize` and `maxSubgroupSize` and **must** be uniform with subgroup scope. The value **may** vary across a single draw or dispatch call, and for fragment shaders **may** vary across a single primitive.

If the pipeline was created with a chained `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT` structure, the `SubgroupSize` decorated variable will match `requiredSubgroupSize`.

If the pipeline was not created with the `VK_PIPELINE_SHADER_STAGE_CREATE_ALLOW_VARYING_SUBGROUP_SIZE_BIT_EXT` flag set and no `VkPipelineShaderStageRequiredSubgroupSizeCreateInfoEXT` structure was chained, the variable decorated with `SubgroupSize` will match `subgroupSize`.

The maximum number of invocations that an implementation can support per subgroup is 128.

The variable decorated with `SubgroupSize` **must** be declared using the `Input` storage class.

The variable decorated with `SubgroupSize` **must** be declared as a scalar 32-bit integer.

**TaskCountNV**

Decorating a variable with the `TaskCountNV` decoration will make that variable contain the task count. The task count specifies the number of subsequent mesh shader workgroups that get generated upon completion of the task shader.

The `TaskCountNV` decoration **must** only be used in task shaders.

Any variable decorated with `TaskCountNV` **must** be declared using the `Output` storage class.
Any variable decorated with `TaskCountNV` must be declared as a scalar 32-bit integer.

**TessCoord**

Decorating a variable with the `TessCoord` built-in decoration will make that variable contain the three-dimensional (u,v,w) barycentric coordinate of the tessellated vertex within the patch. u, v, and w are in the range [0,1] and vary linearly across the primitive being subdivided. For the tessellation modes of `Quads` or `IsoLines`, the third component is always zero.

The `TessCoord` decoration must be used only within tessellation evaluation shaders.

The variable decorated with `TessCoord` must be declared using the `Input` storage class.

The variable decorated with `TessCoord` must be declared as three-component vector of 32-bit floating-point values.

**TessLevelOuter**

Decorating a variable with the `TessLevelOuter` built-in decoration will make that variable contain the outer tessellation levels for the current patch.

In tessellation control shaders, the variable decorated with `TessLevelOuter` can be written to, which controls the tessellation factors for the resulting patch. These values are used by the tessellator to control primitive tessellation and can be read by tessellation evaluation shaders.

In tessellation evaluation shaders, the variable decorated with `TessLevelOuter` can read the values written by the tessellation control shader.

The `TessLevelOuter` decoration must be used only within tessellation control and tessellation evaluation shaders.

In a tessellation control shader, any variable decorated with `TessLevelOuter` must be declared using the `Output` storage class.

In a tessellation evaluation shader, any variable decorated with `TessLevelOuter` must be declared using the `Input` storage class.

Any variable decorated with `TessLevelOuter` must be declared as an array of size four, containing 32-bit floating-point values.

**TessLevelInner**

Decorating a variable with the `TessLevelInner` built-in decoration will make that variable contain the inner tessellation levels for the current patch.

In tessellation control shaders, the variable decorated with `TessLevelInner` can be written to, which controls the tessellation factors for the resulting patch. These values are used by the tessellator to control primitive tessellation and can be read by tessellation evaluation shaders.

In tessellation evaluation shaders, the variable decorated with `TessLevelInner` can read the values written by the tessellation control shader.

The `TessLevelInner` decoration must be used only within tessellation control and tessellation evaluation shaders.
In a tessellation control shader, any variable decorated with `TessLevelInner` must be declared using the *Output* storage class.

In a tessellation evaluation shader, any variable decorated with `TessLevelInner` must be declared using the *Input* storage class.

Any variable decorated with `TessLevelInner` must be declared as an array of size two, containing 32-bit floating-point values.

**VertexIndex**

Decorating a variable with the `VertexIndex` built-in decoration will make that variable contain the index of the vertex that is being processed by the current vertex shader invocation. For non-indexed draws, this variable begins at the `firstVertex` parameter to `vkCmdDraw` or the `firstVertex` member of a structure consumed by `vkCmdDrawIndirect` and increments by one for each vertex in the draw. For indexed draws, its value is the content of the index buffer for the vertex plus the `vertexOffset` parameter to `vkCmdDrawIndexed` or the `vertexOffset` member of the structure consumed by `vkCmdDrawIndexedIndirect`.

The `VertexIndex` decoration must be used only within vertex shaders.

The variable decorated with `VertexIndex` must be declared using the *Input* storage class.

The variable decorated with `VertexIndex` must be declared as a scalar 32-bit integer.

*Note*

`VertexIndex` starts at the same starting value for each instance.

**ViewIndex**

The `ViewIndex` decoration can be applied to a shader input which will be filled with the index of the view that is being processed by the current shader invocation.

If multiview is enabled in the render pass, this value will be one of the bits set in the view mask of the subpass the pipeline is compiled against. If multiview is not enabled in the render pass, this value will be zero.

The `ViewIndex` decoration must not be used within compute shaders.

The variable decorated with `ViewIndex` must be declared using the *Input* storage class.

The variable decorated with `ViewIndex` must be declared as a scalar 32-bit integer.

**ViewportIndex**

Decorating a variable with the `ViewportIndex` built-in decoration will make that variable contain the index of the viewport.

In a mesh, vertex, tessellation evaluation, or geometry shader, the variable decorated with `ViewportIndex` can be written to with the viewport index to which the primitive produced by that shader will be directed.

The selected viewport index is used to select the viewport transform, scissor rectangle, and
exclusive scissor rectangle.

The last active *vertex processing stage* (in pipeline order) controls the `ViewportIndex` that is used. Outputs in previous shader stages are not used, even if the last stage fails to write the `ViewportIndex`.

If the last active vertex processing stage shader entry point's interface does not include a variable decorated with `ViewportIndex`, then the first viewport is used. If a vertex processing stage shader entry point's interface includes a variable decorated with `ViewportIndex`, it must write the same value to `ViewportIndex` for all output vertices of a given primitive.

The `ViewportIndex` decoration must be used only within mesh, vertex, tessellation evaluation, geometry, and fragment shaders.

In a mesh, vertex, tessellation evaluation, or geometry shader, any variable decorated with `ViewportIndex` must be declared using the `Output` storage class.

In a fragment shader, the variable decorated with `ViewportIndex` contains the viewport index of the primitive that the fragment invocation belongs to.

In a fragment shader, any variable decorated with `ViewportIndex` must be declared using the `Input` storage class.

Any variable decorated with `ViewportIndex` must be declared as a scalar 32-bit integer.

**ViewportMaskNV**

Decorating a variable with the `ViewportMaskNV` built-in decoration will make that variable contain the viewport mask.

In a mesh, vertex, tessellation evaluation, or geometry shader, the variable decorated with `ViewportMaskNV` can be written to with the mask of which viewports the primitive produced by that shader will directed.

The `ViewportMaskNV` variable must be an array that has ⌈(VkPhysicalDeviceLimits::maxViewports / 32)⌉ elements. When a shader writes to this variable, bit B of element M controls whether a primitive is emitted to viewport 32 × M + B. The viewports indicated by the mask are used to select the viewport transform, scissor rectangle, and exclusive scissor rectangle that a primitive will be transformed by.

The last active *vertex processing stage* (in pipeline order) controls the `ViewportMaskNV` that is used. Outputs in previous shader stages are not used, even if the last stage fails to write the `ViewportMaskNV`. When `ViewportMaskNV` is written by the final vertex processing stage, any variable decorated with `ViewportIndex` in the fragment shader will have the index of the viewport that was used in generating that fragment.

If a vertex processing stage shader entry point's interface includes a variable decorated with `ViewportMaskNV`, it must write the same value to `ViewportMaskNV` for all output vertices of a given primitive.

The `ViewportMaskNV` decoration must be used only within mesh, vertex, tessellation evaluation, and geometry shaders.
Any variable decorated with `ViewportMaskNV` must be declared using the `Output` storage class.

Any variable decorated with `ViewportMaskNV` must be declared as an array of 32-bit integers.

`ViewportMaskPerViewNV`  
Decorating a variable with the `ViewportMaskPerViewNV` built-in decoration will make that variable contain the mask of viewports primitives are broadcast to, for each view.

The `ViewportMaskPerViewNV` decoration must be used only within mesh, vertex, tessellation control, tessellation evaluation, and geometry shaders.

Any variable decorated with `ViewportMaskPerViewNV` must be declared using the `Output` storage class.

The value written to an element of `ViewportMaskPerViewNV` in the last vertex processing stage is a bitmask indicating which viewports the primitive will be directed to. The primitive will be broadcast to the viewport corresponding to each non-zero bit of the bitmask, and that viewport index is used to select the viewport transform, scissor rectangle, and exclusive scissor rectangle, for each view. The same values must be written to all vertices in a given primitive, or else the set of viewports used for that primitive is undefined.

Any variable decorated with `ViewportMaskPerViewNV` must be declared as an array of scalar 32-bit integers with at least as many elements as the maximum view in the subpass's view mask plus one. The array must be indexed by a constant or specialization constant.

Elements of the array correspond to views in a multiview subpass, and those elements corresponding to views in the view mask of the subpass the shader is compiled against will be used as the viewport mask value for those views. `ViewportMaskPerViewNV` output in an earlier vertex processing stage is not available as an input in the subsequent vertex processing stage.

Although `ViewportMaskNV` is an array, `ViewportMaskPerViewNV` is not a two-dimensional array. Instead, `ViewportMaskPerViewNV` is limited to 32 viewports.

`WarpsPerSMNV`  
Decorating a variable with the `WarpsPerSMNV` built-in decoration will make that variable contain the maximum number of warps executing on a SM.

The variable decorated with `WarpsPerSMNV` must be declared using the `Input` storage class.

The variable decorated with `WarpsPerSMNV` must be declared as a scalar 32-bit integer value.

`WarpIDNV`  
Decorating a variable with the `WarpIDNV` built-in decoration will make that variable contain the ID of the warp on a SM on which the current shader invocation is running. This variable is in the range [0, `WarpsPerSMNV`-1].

The variable decorated with `WarpIDNV` must be declared using the `Input` storage class.

The variable decorated with `WarpIDNV` must be declared as a scalar 32-bit integer value.
WorkgroupId
Decorating a variable with the WorkgroupId built-in decoration will make that variable contain the global workgroup that the current invocation is a member of. Each component ranges from a base value to a base + count value, based on the parameters passed into the dispatch commands.

The WorkgroupId decoration must be used only within task, mesh, or compute shaders.

The variable decorated with WorkgroupId must be declared using the Input storage class.

The variable decorated with WorkgroupId must be declared as a three-component vector of 32-bit integers.

WorkgroupSize
Decorating an object with the WorkgroupSize built-in decoration will make that object contain the dimensions of a local workgroup. If an object is decorated with the WorkgroupSize decoration, this must take precedence over any execution mode set for LocalSize.

The WorkgroupSize decoration must be used only within task, mesh, or compute shaders.

The object decorated with WorkgroupSize must be a specialization constant or a constant.

The object decorated with WorkgroupSize must be declared as a three-component vector of 32-bit integers.

WorldRayDirectionKHR
A variable decorated with the WorldRayDirectionKHR decoration will specify the direction of the ray being processed, in world space.

The WorldRayDirectionKHR decoration must only be used within intersection, any-hit, closest hit, and miss shaders.

Any variable decorated with WorldRayDirectionKHR must be declared using the Input storage class.

Any variable decorated with WorldRayDirectionKHR must be declared as a three-component vector of 32-bit floating-point values.

WorldRayOriginKHR
A variable decorated with the WorldRayOriginKHR decoration will specify the origin of the ray being processed, in world space.

The WorldRayOriginKHR decoration must only be used within intersection, any-hit, closest hit, and miss shaders.

Any variable decorated with WorldRayOriginKHR must be declared using the Input storage class.

Any variable decorated with WorldRayOriginKHR must be declared as a three-component vector of 32-bit floating-point values.
**WorldToObjectKHR**

A variable decorated with the `WorldToObjectKHR` decoration will contain the current world-to-object transformation matrix, which is determined by the instance of the current intersection.

The `WorldToObjectKHR` decoration **must** only be used within intersection, any-hit, and closest hit shaders.

Any variable decorated with `WorldToObjectKHR` **must** be declared using the `Input` storage class.

Any variable decorated with `WorldToObjectKHR` **must** be declared as a matrix with four columns of three-component vectors of 32-bit floating-point values.
Chapter 15. Image Operations

15.1. Image Operations Overview

Vulkan Image Operations are operations performed by those SPIR-V Image Instructions which take an OpTypeImage (representing a VkImageView) or OpTypeSampledImage (representing a (VkImageView, VkSampler) pair) and texel coordinates as operands, and return a value based on one or more neighboring texture elements (texels) in the image.

Note
Texel is a term which is a combination of the words texture and element. Early interactive computer graphics supported texture operations on textures, a small subset of the image operations on images described here. The discrete samples remain essentially equivalent, however, so we retain the historical term texel to refer to them.

Image Operations include the functionality of the following SPIR-V Image Instructions:

- **OpImageSample** and **OpImageSparseSample** read one or more neighboring texels of the image, and filter the texel values based on the state of the sampler.
  - Instructions with ImplicitLod in the name determine the LOD used in the sampling operation based on the coordinates used in neighboring fragments.
  - Instructions with ExplicitLod in the name determine the LOD used in the sampling operation based on additional coordinates.
  - Instructions with Proj in the name apply homogeneous projection to the coordinates.
- **OpImageFetch** and **OpImageSparseFetch** return a single texel of the image. No sampler is used.
- **OpImageGather** and **OpImageSparseGather** read neighboring texels and return a single component of each.
- **OpImageRead** (and **OpImageSparseRead**) and **OpImageWrite** read and write, respectively, a texel in the image. No sampler is used.
- **OpImageSampleFootprintNV** identifies and returns information about the set of texels in the image that would be accessed by an equivalent OpImageSample* instruction.
- Instructions with Dref in the name apply depth comparison on the texel values.
- Instructions with Sparse in the name additionally return a sparse residency code.

15.1.1. Texel Coordinate Systems

Images are addressed by texel coordinates. There are three texel coordinate systems:

- normalized texel coordinates [0.0, 1.0]
- unnormalized texel coordinates [0.0, width / height / depth]
- integer texel coordinates [0, width / height / depth]
SPIR-V **OpImageFetch**, **OpImageSparseFetch**, **OpImageRead**, **OpImageSparseRead**, and **OpImageWrite** instructions use integer texel coordinates. Other image instructions can use either normalized or unnormalized texel coordinates (selected by the `unnormalizedCoordinates` state of the sampler used in the instruction), but there are limitations on what operations, image state, and sampler state is supported. Normalized coordinates are logically converted to unnormalized as part of image operations, and certain steps are only performed on normalized coordinates. The array layer coordinate is always treated as unnormalized even when other coordinates are normalized.

Normalized texel coordinates are referred to as \((s,t,r,q,a)\), with the coordinates having the following meanings:

- **s**: Coordinate in the first dimension of an image.
- **t**: Coordinate in the second dimension of an image.
- **r**: Coordinate in the third dimension of an image.
  - \((s,t,r)\) are interpreted as a direction vector for Cube images.
- **q**: Fourth coordinate, for homogeneous (projective) coordinates.
- **a**: Coordinate for array layer.

The coordinates are extracted from the SPIR-V operand based on the dimensionality of the image variable and type of instruction. For **Proj** instructions, the components are in order \((s \[,t\] \[,r\] q)\), with \(t\) and \(r\) being conditionally present based on the **Dim** of the image. For non-**Proj** instructions, the coordinates are \((s \[,t\] \[,r\] \[,a\])\), with \(t\) and \(r\) being conditionally present based on the **Dim** of the image and \(a\) being conditionally present based on the **Arrayed** property of the image. Projective image instructions are not supported on **Arrayed** images.

Unnormalized texel coordinates are referred to as \((u,v,w,a)\), with the coordinates having the following meanings:

- **u**: Coordinate in the first dimension of an image.
- **v**: Coordinate in the second dimension of an image.
- **w**: Coordinate in the third dimension of an image.
- **a**: Coordinate for array layer.

Only the \(u\) and \(v\) coordinates are directly extracted from the SPIR-V operand, because only 1D and 2D (non-**Arrayed**) dimensionalities support unnormalized coordinates. The components are in order \((u \[,v\])\), with \(v\) being conditionally present when the dimensionality is 2D. When normalized coordinates are converted to unnormalized coordinates, all four coordinates are used.

Integer texel coordinates are referred to as \((i,j,k,l,n)\), with the coordinates having the following meanings:

- **i**: Coordinate in the first dimension of an image.
- **j**: Coordinate in the second dimension of an image.
- **k**: Coordinate in the third dimension of an image.
- **l**: Coordinate for array layer.
• n: Index of the sample within the texel.

They are extracted from the SPIR-V operand in order (i, [j], [k], [l]), with j and k conditionally present based on the Dim of the image, and l conditionally present based on the Arrayed property of the image. n is conditionally present and is taken from the Sample image operand.

For all coordinate types, unused coordinates are assigned a value of zero.

Figure 3. Texel Coordinate Systems, Linear Filtering

The Texel Coordinate Systems - For the example shown of an 8×4 texel two dimensional image.

• Normalized texel coordinates:
  ◦ The s coordinate goes from 0.0 to 1.0.
  ◦ The t coordinate goes from 0.0 to 1.0.

• Unnormalized texel coordinates:
  ◦ The u coordinate within the range 0.0 to 8.0 is within the image, otherwise it is outside the image.
  ◦ The v coordinate within the range 0.0 to 4.0 is within the image, otherwise it is outside the image.

• Integer texel coordinates:
  ◦ The i coordinate within the range 0 to 7 addresses texels within the image, otherwise it is outside the image.
  ◦ The j coordinate within the range 0 to 3 addresses texels within the image, otherwise it outside the image.

• Also shown for linear filtering:
  ◦ Given the unnormalized coordinates (u,v), the four texels selected are i0j0, i1j0, i0j1, and i1j1.
The fractions $\alpha$ and $\beta$.
Given the offset $\Delta_i$ and $\Delta_j$, the four texels selected by the offset are $i_0j', i_1j', i_0j$, and $i_1j$.

**Note**
For formats with reduced-resolution channels, $\Delta_i$ and $\Delta_j$ are relative to the resolution of the highest-resolution channel, and therefore may be divided by two relative to the unnormalized coordinate space of the lower-resolution channels.

---

**Figure 4. Texel Coordinate Systems, Nearest Filtering**

The Texel Coordinate Systems - For the example shown of an $8 \times 4$ texel two dimensional image.

- Texel coordinates as above. Also shown for nearest filtering:
  - Given the unnormalized coordinates $(u,v)$, the texel selected is $ij$.
  - Given the offset $\Delta_i$ and $\Delta_j$, the texel selected by the offset is $ij'$.

For corner-sampled images, the texel samples are located at the grid intersections instead of the texel centers.
15.2. Conversion Formulas

15.2.1. RGB to Shared Exponent Conversion

An RGB color (red, green, blue) is transformed to a shared exponent color (red\textsubscript{shared}, green\textsubscript{shared}, blue\textsubscript{shared}, exp\textsubscript{shared}) as follows:

First, the components (red, green, blue) are clamped to (red\textsubscript{clamped}, green\textsubscript{clamped}, blue\textsubscript{clamped}) as:

\[ \text{red}\textsubscript{clamped} = \max(0, \min(\text{sharedexp}\textsubscript{max}, \text{red})) \]
\[ \text{green}\textsubscript{clamped} = \max(0, \min(\text{sharedexp}\textsubscript{max}, \text{green})) \]
\[ \text{blue}\textsubscript{clamped} = \max(0, \min(\text{sharedexp}\textsubscript{max}, \text{blue})) \]

where:

\[ N = 9 \]
\[ B = 15 \]
\[ E\textsubscript{max} = 31 \]
\[ \text{sharedexp}\textsubscript{max} = \frac{(2^N - 1)}{2^N} \times 2^{(E\textsubscript{max} - B)} \]

Note

NaN, if supported, is handled as in IEEE 754-2008 \texttt{minNum()} and \texttt{maxNum()}. This results in any NaN being mapped to zero.
The largest clamped component, $\max_{\text{clamped}}$, is determined:

$$\max_{\text{clamped}} = \max(\text{red}_{\text{clamped}}, \text{green}_{\text{clamped}}, \text{blue}_{\text{clamped}})$$

A preliminary shared exponent $\exp'$ is computed:

$$\exp' = \begin{cases} \log_2(\max_{\text{clamped}}) + (B + 1) & \text{for } \max_{\text{clamped}} > 2^{-(B + 1)} \\ 0 & \text{for } \max_{\text{clamped}} \leq 2^{-(B + 1)} \end{cases}$$

The shared exponent $\exp_{\text{shared}}$ is computed:

$$\max_{\text{shared}} = \frac{\max_{\text{clamped}}}{2^{(\exp' - B - N)}} + \frac{1}{2}$$

$$\exp_{\text{shared}} = \begin{cases} \exp' & \text{for } 0 \leq \max_{\text{shared}} < 2^N \\ \exp' + 1 & \text{for } \max_{\text{shared}} = 2^N \end{cases}$$

Finally, three integer values in the range 0 to $2^N$ are computed:

$$\text{red}_{\text{shared}} = \left\lfloor \frac{\text{red}_{\text{clamped}}}{2^{(\exp_{\text{shared}} - B - N)}} + \frac{1}{2} \right\rfloor$$

$$\text{green}_{\text{shared}} = \left\lfloor \frac{\text{green}_{\text{clamped}}}{2^{(\exp_{\text{shared}} - B - N)}} + \frac{1}{2} \right\rfloor$$

$$\text{blue}_{\text{shared}} = \left\lfloor \frac{\text{blue}_{\text{clamped}}}{2^{(\exp_{\text{shared}} - B - N)}} + \frac{1}{2} \right\rfloor$$

### 15.2.2. Shared Exponent to RGB

A shared exponent color ($\text{red}_{\text{shared}}, \text{green}_{\text{shared}}, \text{blue}_{\text{shared}}, \exp_{\text{shared}}$) is transformed to an RGB color (red, green, blue) as follows:

$$\text{red} = \text{red}_{\text{shared}} \times 2^{(\exp_{\text{shared}} - B - N)}$$

$$\text{green} = \text{green}_{\text{shared}} \times 2^{(\exp_{\text{shared}} - B - N)}$$

$$\text{blue} = \text{blue}_{\text{shared}} \times 2^{(\exp_{\text{shared}} - B - N)}$$

where:

- $N = 9$ (number of mantissa bits per component)
- $B = 15$ (exponent bias)
15.3. Texel Input Operations

Texel input instructions are SPIR-V image instructions that read from an image. Texel input operations are a set of steps that are performed on state, coordinates, and texel values while processing a texel input instruction, and which are common to some or all texel input instructions. They include the following steps, which are performed in the listed order:

- Validation operations
  - Instruction/Sampler/Image validation
  - Coordinate validation
  - Sparse validation
  - Layout validation
- Format conversion
- Texel replacement
- Depth comparison
- Conversion to RGBA
- Component swizzle
- Chroma reconstruction
- \( Y'C_bC_r \) conversion

For texel input instructions involving multiple texels (for sampling or gathering), these steps are applied for each texel that is used in the instruction. Depending on the type of image instruction, other steps are conditionally performed between these steps or involving multiple coordinate or texel values.

If Chroma Reconstruction is implicit, Texel Filtering instead takes place during chroma reconstruction, before sampler \( Y'C_bC_r \) conversion occurs.

15.3.1. Texel Input Validation Operations

Texel input validation operations inspect instruction/image/sampler state or coordinates, and in certain circumstances cause the texel value to be replaced or become undefined. There are a series of validations that the texel undergoes.

Instruction/Sampler/Image View Validation

There are a number of cases where a SPIR-V instruction can mismatch with the sampler, the image view, or both. There are a number of cases where the sampler can mismatch with the image view. In such cases the value of the texel returned is undefined.

These cases include:

- The sampler \( \text{borderColor} \) is an integer type and the image view format is not one of the \( \text{VkFormat} \) integer types or a stencil component of a depth/stencil format.
• The sampler `borderColor` is a float type and the image view `format` is not one of the `VkFormat` float types or a depth component of a depth/stencil format.

• The sampler `borderColor` is one of the opaque black colors (`VK_BORDER_COLOR_FLOAT_OPAQUE_BLACK` or `VK_BORDER_COLOR_INT_OPAQUE_BLACK`) and the image view `VkComponentSwizzle` for any of the `VkComponentMapping` components is not `VK_COMPONENT_SWIZZLE_IDENTITY`.

• The `VkImageLayout` of any subresource in the image view does not match that specified in `VkDescriptorImageInfo::imageLayout` used to write the image descriptor.

• If the instruction is `OpImageRead` or `OpImageSparseRead` and the `shaderStorageImageReadWithoutFormat` feature is not enabled, or the instruction is `OpImageWrite` and the `shaderStorageImageWriteWithoutFormat` feature is not enabled, then the SPIR-V Image Format must be compatible with the image view’s `format`.

• The sampler `unnormalizedCoordinates` is `VK_TRUE` and any of the limitations of unnormalized coordinates are violated.

• The sampler was created with `flags` containing `VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT` and the image was not created with `flags` containing `VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT`.

• The sampler was not created with `flags` containing `VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT` and the image was created with `flags` containing `VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT`.

• The sampler was created with `flags` containing `VK_SAMPLER_CREATE_SUBSAMPLED_BIT_EXT` and is used with a function that is not `OpImageSampleImplicitLod` or `OpImageSampleExplicitLod`, or is used with operands `Offset` or `ConstOffsets`.

• The SPIR-V instruction is one of the `OpImage*Dref*` instructions and the sampler `compareEnable` is `VK_FALSE`.

• The SPIR-V instruction is not one of the `OpImage*Dref*` instructions and the sampler `compareEnable` is `VK_TRUE`.

• The SPIR-V instruction is one of the `OpImage*Dref*` instructions and the image view `format` is not one of the depth/stencil formats with a depth component, or the image view aspect is not `VK_IMAGE_ASPECT_DEPTH_BIT`.

• The SPIR-V instruction’s image variable’s properties are not compatible with the image view:
  ◦ Rules for `viewType`:
    ✷ `VK_IMAGE_VIEW_TYPE_1D` must have `Dim = 1D`, `Arrayed = 0`, `MS = 0`.
    ✷ `VK_IMAGE_VIEW_TYPE_2D` must have `Dim = 2D`, `Arrayed = 0`.
    ✷ `VK_IMAGE_VIEW_TYPE_3D` must have `Dim = 3D`, `Arrayed = 0`, `MS = 0`.
    ✷ `VK_IMAGE_VIEW_TYPE_CUBE` must have `Dim = Cube`, `Arrayed = 0`, `MS = 0`.
    ✷ `VK_IMAGE_VIEW_TYPE_1D_ARRAY` must have `Dim = 1D`, `Arrayed = 1`, `MS = 0`.
    ✷ `VK_IMAGE_VIEW_TYPE_2D_ARRAY` must have `Dim = 2D`, `Arrayed = 1`.
    ✷ `VK_IMAGE_VIEW_TYPE_CUBE_ARRAY` must have `Dim = Cube`, `Arrayed = 1`, `MS = 0`.
  ◦ If the image was created with `VkImageCreateInfo::samples` equal to `VK_SAMPLE_COUNT_1_BIT`, the instruction must have `MS = 0`.
  ◦ If the image was created with `VkImageCreateInfo::samples` not equal to `VK_SAMPLE_COUNT_1_BIT`, the instruction must have `MS = 1`.
• If the image was created with `VkImageCreateInfo::flags` containing `VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV`, the sampler addressing modes must only use a `VkSamplerAddressMode` of `VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE`.

• The SPIR-V instruction is `OpImageSampleFootprintNV` with `Dim = 2D` and `addressModeU` or `addressModeV` in the sampler is not `VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE`.

• The SPIR-V instruction is `OpImageSampleFootprintNV` with `Dim = 3D` and `addressModeU`, `addressModeV`, or `addressModeW` in the sampler is not `VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE`.

• The sampler was created with a specified `VkSamplerCustomBorderColorCreateInfoEXT::format` which does not match the `VkFormat` of the image view(s) it is sampling.

• The sampler is sampling an image view of `VK_FORMAT_B4G4R4A4_UNORM_PACK16` format without a specified `VkSamplerCustomBorderColorCreateInfoEXT::format`.

Only `OpImageSample*` and `OpImageSparseSample*` can be used with a sampler that enables sampler Y'CbCr conversion.

`OpImageFetch`, `OpImageSparseFetch`, `OpImage*Gather`, and `OpImageSparse*Gather` must not be used with a sampler that enables sampler Y'CbCr conversion.

The `ConstOffset` and `Offset` operands must not be used with a sampler that enables sampler Y'CbCr conversion.

**Integer Texel Coordinate Validation**

Integer texel coordinates are validated against the size of the image level, and the number of layers and number of samples in the image. For SPIR-V instructions that use integer texel coordinates, this is performed directly on the integer coordinates. For instructions that use normalized or unnormalized texel coordinates, this is performed on the coordinates that result after conversion to integer texel coordinates.

If the integer texel coordinates do not satisfy all of the conditions

\[
0 \leq i < w_s \\
0 \leq j < h_s \\
0 \leq k < d_s \\
0 \leq l < \text{layers} \\
0 \leq n < \text{samples}
\]

where:
\( w_s = \text{width of the image level} \)

\( h_s = \text{height of the image level} \)

\( d_s = \text{depth of the image level} \)

\( \text{layers} = \text{number of layers in the image} \)

\( \text{samples} = \text{number of samples per texel in the image} \)

then the texel fails integer texel coordinate validation.

There are four cases to consider:

1. Valid Texel Coordinates
   - If the texel coordinates pass validation (that is, the coordinates lie within the image),
     then the texel value comes from the value in image memory.

2. Border Texel
   - If the texel coordinates fail validation, and
   - If the read is the result of an image sample instruction or image gather instruction, and
   - If the image is not a cube image,
     then the texel is a border texel and \textit{texel replacement} is performed.

3. Invalid Texel
   - If the texel coordinates fail validation, and
   - If the read is the result of an image fetch instruction, image read instruction, or atomic instruction,
     then the texel is an invalid texel and \textit{texel replacement} is performed.

4. Cube Map Edge or Corner

   Otherwise the texel coordinates lie beyond the edges or corners of the selected cube map face, and \textit{cube map edge handling} is performed.

\textbf{Cube Map Edge Handling}

If the texel coordinates lie beyond the edges or corners of the selected cube map face, the following steps are performed. Note that this does not occur when using \texttt{VK\_FILTER\_NEAREST} filtering within a mip level, since \texttt{VK\_FILTER\_NEAREST} is treated as using \texttt{VK\_SAMPLER\_ADDRESS\_MODE\_CLAMP\_TO\_EDGE}. 
• Cube Map Edge Texel
  ◦ If the texel lies beyond the selected cube map face in either only i or only j, then the coordinates (i,j) and the array layer l are transformed to select the adjacent texel from the appropriate neighboring face.

• Cube Map Corner Texel
  ◦ If the texel lies beyond the selected cube map face in both i and j, then there is no unique neighboring face from which to read that texel. The texel should be replaced by the average of the three values of the adjacent texels in each incident face. However, implementations may replace the cube map corner texel by other methods. The methods are subject to the constraint that for linear filtering if the three available texels have the same value, the resulting filtered texel must have that value, and for cubic filtering if the twelve available samples have the same value, the resulting filtered texel must have that value.

Sparse Validation
If the texel reads from an unbound region of a sparse image, the texel is a sparse unbound texel, and processing continues with texel replacement.

Layout Validation
If all planes of a disjoint multi-planar image are not in the same image layout, the image must not be sampled with sampler Y’CnCn conversion enabled.

15.3.2. Format Conversion
Texels undergo a format conversion from the VkFormat of the image view to a vector of either floating point or signed or unsigned integer components, with the number of components based on the number of components present in the format.

• Color formats have one, two, three, or four components, according to the format.
• Depth/stencil formats are one component. The depth or stencil component is selected by the aspectMask of the image view.

Each component is converted based on its type and size (as defined in the Format Definition section for each VkFormat), using the appropriate equations in 16-Bit Floating-Point Numbers, Unsigned 11-Bit Floating-Point Numbers, Unsigned 10-Bit Floating-Point Numbers, Fixed-Point Data Conversion, and Shared Exponent to RGB. Signed integer components smaller than 32 bits are sign-extended.

If the image view format is sRGB, the color components are first converted as if they are UNORM, and then sRGB to linear conversion is applied to the R, G, and B components as described in the “sRGB EOTF” section of the Khronos Data Format Specification. The A component, if present, is unchanged.

If the image view format is block-compressed, then the texel value is first decoded, then converted based on the type and number of components defined by the compressed format.
15.3.3. Texel Replacement

A texel is replaced if it is one (and only one) of:

- a border texel,
- an invalid texel, or
- a sparse unbound texel.

Border texels are replaced with a value based on the image format and the `borderColor` of the sampler. The border color is:

<table>
<thead>
<tr>
<th>Sampler</th>
<th>Corresponding Border Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>VK_BORDER_COLOR_FLOAT_TRANSPARENT_BLACK</td>
<td>[B_r, B_g, B_b, B_a] = [0.0, 0.0, 0.0, 0.0]</td>
</tr>
<tr>
<td>VK_BORDER_COLOR_FLOAT_OPAQUE_BLACK</td>
<td>[B_r, B_g, B_b, B_a] = [0.0, 0.0, 0.0, 1.0]</td>
</tr>
<tr>
<td>VK_BORDER_COLOR_FLOAT_OPAQUE_WHITE</td>
<td>[B_r, B_g, B_b, B_a] = [1.0, 1.0, 1.0, 1.0]</td>
</tr>
<tr>
<td>VK_BORDER_COLOR_INT_TRANSPARENT_BLACK</td>
<td>[B_r, B_g, B_b, B_a] = [0, 0, 0, 0]</td>
</tr>
<tr>
<td>VK_BORDER_COLOR_INT_OPAQUE_BLACK</td>
<td>[B_r, B_g, B_b, B_a] = [0, 0, 0, 1]</td>
</tr>
<tr>
<td>VK_BORDER_COLOR_INT_OPAQUE_WHITE</td>
<td>[B_r, B_g, B_b, B_a] = [1, 1, 1, 1]</td>
</tr>
<tr>
<td>VK_BORDER_COLOR_FLOAT_CUSTOM_EXT</td>
<td>[B_r, B_g, B_b, B_a] = [U_r, U_g, U_b, U_a]</td>
</tr>
<tr>
<td>VK_BORDER_COLOR_INT_CUSTOM_EXT</td>
<td>[B_r, B_g, B_b, B_a] = [U_r, U_g, U_b, U_a]</td>
</tr>
</tbody>
</table>

**Note**

The names `VK_BORDER_COLOR_*_TRANSPARENT_BLACK`, `VK_BORDER_COLOR_*_OPAQUE_BLACK`, and `VK_BORDER_COLOR_*_OPAQUE_WHITE` are meant to describe which components are zeros and ones in the vocabulary of compositing, and are not meant to imply that the numerical value of `VK_BORDER_COLOR_INT_OPAQUE_WHITE` is a saturating value for integers.

This is substituted for the texel value by replacing the number of components in the image format

<table>
<thead>
<tr>
<th>Texel Aspect or Format</th>
<th>Component Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Depth aspect</td>
<td>D = B_r</td>
</tr>
<tr>
<td>Stencil aspect</td>
<td>S = B_r</td>
</tr>
<tr>
<td>One component color format</td>
<td>Color_r = B_r</td>
</tr>
<tr>
<td>Two component color format</td>
<td>[Color_r,Color_g] = [B_r,B_g]</td>
</tr>
<tr>
<td>Three component color format</td>
<td>[Color_r,Color_g,Color_b] = [B_r,B_g,B_b]</td>
</tr>
<tr>
<td>Four component color format</td>
<td>[Color_r,Color_g,Color_b,Color_a] = [B_r,B_g,B_b,B_a]</td>
</tr>
</tbody>
</table>

The value returned by a read of an invalid texel is undefined, unless that read operation is from a
buffer resource and the `robustBufferAccess` feature is enabled. In that case, an invalid texel is replaced as described by the `robustBufferAccess` feature. If the access is to an image resource and the x, y, z, or layer coordinate validation fails and `robustImageAccess2` is enabled, zero values must be returned. If only the sample index was invalid, the values returned are undefined.

Loads from a null descriptor return a four component color value of all zeros. However, for storage images and storage texel buffers using an explicit SPIR-V Image Format, loads from a null descriptor may return an alpha value of 1 (float or integer, depending on format) if the format doesn’t include alpha.

If the `VkPhysicalDeviceSparseProperties::residencyNonResidentStrict` property is `VK_TRUE`, a sparse unbound texel is replaced with 0 or 0.0 values for integer and floating-point components of the image format, respectively.

If `residencyNonResidentStrict` is `VK_FALSE`, the value of the sparse unbound texel is undefined.

### 15.3.4. Depth Compare Operation

If the image view has a depth/stencil format, the depth component is selected by the `aspectMask`, and the operation is a `Dref` instruction, a depth comparison is performed. The value of the result D is 1.0 if the result of the compare operation is true, and 0.0 otherwise. The compare operation is selected by the `compareOp` member of the sampler.

\[
D = \begin{cases} 
1.0 & \text{if } D_{\text{ref}} \leq D \text{ for LEQUAL} \\
1.0 & \text{if } D_{\text{ref}} \geq D \text{ for GEQUAL} \\
0.0 & \text{if } D_{\text{ref}} < D \text{ for LESS} \\
0.0 & \text{if } D_{\text{ref}} > D \text{ for GREATER} \\
D_{\text{ref}} = D \text{ for EQUAL} \\
true & \text{for ALWAYS} \\
false & \text{for NEVER} \\
\end{cases}
\]

where, in the depth comparison:

\[D_{\text{ref}} = \text{shaderOp.D}_{\text{ref}} \text{ (from optional SPIR-V operand)}\]

\[D \text{ (texel depth value)}\]

### 15.3.5. Conversion to RGBA

The texel is expanded from one, two, or three components to four components based on the image base color:

<table>
<thead>
<tr>
<th>Texel Aspect or Format</th>
<th>RGBA Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>Depth aspect</td>
<td>([\text{Color}_r,\text{Color}_g,\text{Color}_b, \text{Color}_a] = [D,0,0,1])</td>
</tr>
</tbody>
</table>

Table 24. Texel Color After Conversion To RGBA
<table>
<thead>
<tr>
<th>Texel Aspect or Format</th>
<th>RGBA Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stencil aspect</td>
<td>[Color&lt;sub&gt;r&lt;/sub&gt;,Color&lt;sub&gt;g&lt;/sub&gt;,Color&lt;sub&gt;b&lt;/sub&gt;, Color&lt;sub&gt;a&lt;/sub&gt;] = [S,0,0,one]</td>
</tr>
<tr>
<td>One component color format</td>
<td>[Color&lt;sub&gt;r&lt;/sub&gt;,Color&lt;sub&gt;g&lt;/sub&gt;,Color&lt;sub&gt;b&lt;/sub&gt;, Color&lt;sub&gt;a&lt;/sub&gt;] = [Color&lt;sub&gt;r&lt;/sub&gt;,0,0,one]</td>
</tr>
<tr>
<td>Two component color format</td>
<td>[Color&lt;sub&gt;r&lt;/sub&gt;,Color&lt;sub&gt;g&lt;/sub&gt;,Color&lt;sub&gt;b&lt;/sub&gt;, Color&lt;sub&gt;a&lt;/sub&gt;] = [Color&lt;sub&gt;r&lt;/sub&gt;,Color&lt;sub&gt;g&lt;/sub&gt;,0,one]</td>
</tr>
<tr>
<td>Three component color format</td>
<td>[Color&lt;sub&gt;r&lt;/sub&gt;,Color&lt;sub&gt;g&lt;/sub&gt;,Color&lt;sub&gt;b&lt;/sub&gt;, Color&lt;sub&gt;a&lt;/sub&gt;] = [Color&lt;sub&gt;r&lt;/sub&gt;,Color&lt;sub&gt;g&lt;/sub&gt;,Color&lt;sub&gt;b&lt;/sub&gt;,one]</td>
</tr>
<tr>
<td>Four component color format</td>
<td>[Color&lt;sub&gt;r&lt;/sub&gt;,Color&lt;sub&gt;g&lt;/sub&gt;,Color&lt;sub&gt;b&lt;/sub&gt;, Color&lt;sub&gt;a&lt;/sub&gt;] = [Color&lt;sub&gt;r&lt;/sub&gt;,Color&lt;sub&gt;g&lt;/sub&gt;,Color&lt;sub&gt;b&lt;/sub&gt;,Color&lt;sub&gt;a&lt;/sub&gt;]</td>
</tr>
</tbody>
</table>

where one = 1.0f for floating-point formats and depth aspects, and one = 1 for integer formats and stencil aspects.

### 15.3.6. Component Swizzle

All texel input instructions apply a swizzle based on:

- the VkComponentSwizzle enums in the components member of the VkImageViewCreateInfo structure for the image being read if sampler Y'C<sub>b</sub>C<sub>r</sub> conversion is not enabled, and
- the VkComponentSwizzle enums in the components member of the VkSamplerYcbcrConversionCreateInfo structure for the sampler Y'C<sub>b</sub>C<sub>r</sub> conversion if sampler Y'C<sub>b</sub>C<sub>r</sub> conversion is enabled.

The swizzle can rearrange the components of the texel, or substitute zero or one for any components. It is defined as follows for each color component:

\[
\text{Color}_{\text{component}} = \begin{cases} 
    \text{Color}_r & \text{for RED swizzle} \\
    \text{Color}_g & \text{for GREEN swizzle} \\
    \text{Color}_b & \text{for BLUE swizzle} \\
    \text{Color}_a & \text{for ALPHA swizzle} \\
    0 & \text{for ZERO swizzle} \\
    \text{one} & \text{for ONE swizzle} \\
    \text{identity} & \text{for IDENTITY swizzle} 
\end{cases}
\]

where:

\[
\text{one} = \begin{cases} 
    1.0f & \text{for floating point components} \\
    1 & \text{for integer components} 
\end{cases}
\]

\[
\text{identity} = \begin{cases} 
    \text{Color}_r & \text{for component = r} \\
    \text{Color}_g & \text{for component = g} \\
    \text{Color}_b & \text{for component = b} \\
    \text{Color}_a & \text{for component = a} 
\end{cases}
\]

If the border color is one of the VK_BORDER_COLOR_*_OPAQUE_BLACK enums and the VkComponentSwizzle is not VK_COMPONENT_SWIZZLE_IDENTITY for all components (or the equivalent identity mapping), the value of the texel after swizzle is undefined.

### 15.3.7. Sparse Residency

OpImageSparse* instructions return a structure which includes a residency code indicating whether any texels accessed by the instruction are sparse unbound texels. This code can be interpreted by
15.3.8. Chroma Reconstruction

In some color models, the color representation is defined in terms of monochromatic light intensity (often called “luma”) and color differences relative to this intensity, often called “chroma”. It is common for color models other than RGB to represent the chroma channels at lower spatial resolution than the luma channel. This approach is used to take advantage of the eye’s lower spatial sensitivity to color compared with its sensitivity to brightness. Less commonly, the same approach is used with additive color, since the green channel dominates the eye’s sensitivity to light intensity and the spatial sensitivity to color introduced by red and blue is lower.

Lower-resolution channels are “downsampled” by resizing them to a lower spatial resolution than the channel representing luminance. The process of reconstructing a full color value for texture access involves accessing both chroma and luma values at the same location. To generate the color accurately, the values of the lower-resolution channels at the location of the luma samples must be reconstructed from the lower-resolution sample locations, an operation known here as “chroma reconstruction” irrespective of the actual color model.

The location of the chroma samples relative to the luma coordinates is determined by the `xChromaOffset` and `yChromaOffset` members of the `VkSamplerYcbcrConversionCreateInfo` structure used to create the sampler Y’C_bC_r conversion.

The following diagrams show the relationship between unnormalized (u,v) coordinates and (i,j) integer texel positions in the luma channel (shown in black, with circles showing integer sample positions) and the texel coordinates of reduced-resolution chroma channels, shown as crosses in red.

**Note**

If the chroma values are reconstructed at the locations of the luma samples by means of interpolation, chroma samples from outside the image bounds are needed; these are determined according to Wrapping Operation. These diagrams represent this by showing the bounds of the “chroma texel” extending beyond the image bounds, and including additional chroma sample positions where required for interpolation. The limits of a sample for NEAREST sampling is shown as a grid.
Figure 6. 422 downsampling, xChromaOffset=COSITED_EVEN

Figure 7. 422 downsampling, xChromaOffset=MIDPOINT
Figure 8. 420 downsampling, xChromaOffset=COSITED_EVEN, yChromaOffset=COSITED_EVEN

Figure 9. 420 downsampling, xChromaOffset=MIDPOINT, yChromaOffset=COSITED_EVEN
Figure 10. 420 downsampling, xChromaOffset=COSITED_EVEN, yChromaOffset=MIDPOINT

Figure 11. 420 downsampling, xChromaOffset=MIDPOINT, yChromaOffset=MIDPOINT

Reconstruction is implemented in one of two ways:

If the format of the image that is to be sampled sets `VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_CHROMA_RECONSTRUCTION_EXPLICIT_BIT`, or the `VkSamplerYcbcrConversionCreateInfo`'s `forceExplicitReconstruction` is set to `VK_TRUE`, reconstruction is performed as an explicit step independent of filtering, described in the Explicit Reconstruction section.
If the format of the image that is to be sampled does not set `VK_FORMAT_FEATURE_SAMPLED_IMAGE_YCBCR_CONVERSION_CHROMA_RECONSTRUCTION_EXPLICIT_BIT` and if the `VkSamplerYcbcrConversionCreateInfo`'s `forceExplicitReconstruction` is set to `VK_FALSE`, reconstruction is performed as an implicit part of filtering prior to color model conversion, with no separate post-conversion texel filtering step, as described in the Implicit Reconstruction section.

**Explicit Reconstruction**

- If the `chromaFilter` member of the `VkSamplerYcbcrConversionCreateInfo` structure is `VK_FILTER_NEAREST`:
  - If the format’s R and B channels are reduced in resolution in just width by a factor of two relative to the G channel (i.e. this is a “422” format), the $\tau_{ij}[\text{level}]$ values accessed by texel filtering are reconstructed as follows:
    \[
    \begin{align*}
    \tau_R'(i, j) &= \tau_R(i \times 0.5, j)[\text{level}] \\
    \tau_B'(i, j) &= \tau_B(i \times 0.5, j)[\text{level}] 
    \end{align*}
    \]
  - If the format’s R and B channels are reduced in resolution in width and height by a factor of two relative to the G channel (i.e. this is a “420” format), the $\tau_{ij}[\text{level}]$ values accessed by texel filtering are reconstructed as follows:
    \[
    \begin{align*}
    \tau_R'(i, j) &= \tau_R(i \times 0.5, l \times 0.5)[\text{level}] \\
    \tau_B'(i, j) &= \tau_B(i \times 0.5, l \times 0.5)[\text{level}] 
    \end{align*}
    \]

  _Note_
  `xChromaOffset` and `yChromaOffset` have no effect if `chromaFilter` is `VK_FILTER_NEAREST` for explicit reconstruction.

- If the `chromaFilter` member of the `VkSamplerYcbcrConversionCreateInfo` structure is `VK_FILTER_LINEAR`:
  - If the format’s R and B channels are reduced in resolution in just width by a factor of two relative to the G channel (i.e. this is a “422” format):
    - If `xChromaOffset` is `VK_CHROMA_LOCATION_COSITED_EVEN`:
      \[
      \tau_{RB}'(i, j) = \begin{cases} 
      \tau_{RB}(i \times 0.5, j)[\text{level}], & 0.5 \times i = [0.5 \times i] \\
      0.5 \times \tau_{RB}(i \times 0.5, j)[\text{level}] + 0.5 \times \tau_{RB}(i \times 0.5, j)[\text{level}], & 0.5 \times i \neq [0.5 \times i] 
      \end{cases}
      \]
    - If `xChromaOffset` is `VK_CHROMA_LOCATION_MIDPOINT`:
      \[
      \tau_{RB}'(i, j) = \begin{cases} 
      0.25 \times \tau_{RB}(i \times 0.5 - 1, j)[\text{level}] + 0.75 \times \tau_{RB}(i \times 0.5, j)[\text{level}], & 0.5 \times i = [0.5 \times i] \\
      0.75 \times \tau_{RB}(i \times 0.5, j)[\text{level}] + 0.25 \times \tau_{RB}(i \times 0.5 + 1, j)[\text{level}], & 0.5 \times i \neq [0.5 \times i] 
      \end{cases}
      \]
  - If the format’s R and B channels are reduced in resolution in width and height by a factor of two relative to the G channel (i.e. this is a “420” format), a similar relationship applies. Due to the number of options, these formulae are expressed more concisely as follows:
In the case where the texture itself is bilinearly interpolated as described in Texel Filtering, thus requiring four full-color samples for the filtering operation, and where the reconstruction of these samples uses bilinear interpolation in the chroma channels due to \( \text{chromaFilter} = \text{VK\_FILTER\_LINEAR} \), up to nine chroma samples may be required, depending on the sample location.

**Implicit Reconstruction**

Implicit reconstruction takes place by the samples being interpolated, as required by the filter settings of the sampler, except that \( \text{chromaFilter} \) takes precedence for the chroma samples.

If \( \text{chromaFilter} \) is \( \text{VK\_FILTER\_NEAREST} \), an implementation may behave as if \( x\text{ChromaOffset} \) and \( y\text{ChromaOffset} \) were both \( \text{VK\_CHROMA\_LOCATION\_MIDPOINT} \), irrespective of the values set.

This will not have any visible effect if the locations of the luma samples coincide with the location of the samples used for rasterization.

The sample coordinates are adjusted by the downsample factor of the channel (such that, for example, the sample coordinates are divided by two if the channel has a downsample factor of two relative to the luma channel):

\[
\begin{align*}
  u_{RB} & = \begin{cases} 
    0.5 \times (i) & \text{If} \text{ChromaOffset} = \text{COSITED\_EVEN} \\
    0.5 \times (i - 0.5) & \text{If} \text{ChromaOffset} = \text{MIDPOINT} 
  \end{cases} \\
  v_{RB} & = \begin{cases} 
    0.5 \times (j) & \text{If} \text{ChromaOffset} = \text{COSITED\_EVEN} \\
    0.5 \times (j - 0.5) & \text{If} \text{ChromaOffset} = \text{MIDPOINT} 
  \end{cases}
\end{align*}
\]

\[
\begin{align*}
  i_{floor} & = \lfloor i_{RB} \rfloor \\
  j_{floor} & = \lfloor j_{RB} \rfloor \\
  i_{frac} & = i_{RB} - i_{floor} \\
  j_{frac} & = j_{RB} - j_{floor}
\end{align*}
\]

\[
\begin{align*}
  \tau_{RB}(i, j) & = \tau_{RB}(i_{floor}, j_{floor})[\text{level}] & \times (1 - i_{frac}) & \times (1 - j_{frac}) + \\
  \tau_{RB}(i + i_{floor}, j_{floor})[\text{level}] & = (i_{frac}) & \times (1 - j_{frac}) + \\
  \tau_{RB}(i_{floor}, j + j_{floor})[\text{level}] & = (1 - i_{frac}) & \times (j_{frac}) + \\
  \tau_{RB}(i + i_{floor}, j + j_{floor})[\text{level}] & = (1 - i_{frac}) & \times (1 - j_{frac})
\end{align*}
\]

**15.3.9. Sampler Y’C_bC_R Conversion**

Sampler Y’C_bC_R conversion performs the following operations, which an implementation may combine into a single mathematical operation:

- **Sampler Y’C_bC_R Range Expansion**
**Sampler Y’C₈C₉ Model Conversion**

### Sampler Y’C₈C₉ Range Expansion

Sampler Y’C₈C₉ range expansion is applied to color channel values after all texel input operations which are not specific to sampler Y’C₈C₉ conversion. For example, the input values to this stage have been converted using the normal format conversion rules.

Sampler Y’C₈C₉ range expansion is not applied if ycbcrModel is `VK_SAMPLER_YCBCR_MODEL_CONVERSION_RGB_IDENTITY`. That is, the shader receives the vector C’rgba as output by the Component Swizzle stage without further modification.

For other values of ycbcrModel, range expansion is applied to the texel channel values output by the Component Swizzle defined by the components member of VkSamplerYcbcrConversionCreateInfo. Range expansion applies independently to each channel of the image. For the purposes of range expansion and Y’C₈C₉ model conversion, the R and B channels contain color difference (chroma) values and the G channel contains luma. The A channel is not modified by sampler Y’C₈C₉ range expansion.

The range expansion to be applied is defined by the ycbcrRange member of the VkSamplerYcbcrConversionCreateInfo structure:

- If ycbcrRange is `VK_SAMPLER_YCBCR_RANGE_ITU_FULL`, the following transformations are applied:

  \[
  Y' = C'rgba[G] \\
  C_B = C'rgba[B] - \frac{2(n-1)}{(2^n-1)} \\
  C_R = C'rgba[R] - \frac{2(n-1)}{(2^n-1)}
  \]

**Note**

These formulae correspond to the “full range” encoding in the “Quantization schemes” chapter of the Khronos Data Format Specification.

Should any future amendments be made to the ITU specifications from which these equations are derived, the formulae used by Vulkan may also be updated to maintain parity.

- If ycbcrRange is `VK_SAMPLER_YCBCR_RANGE_ITU_NARROW`, the following transformations are applied:

  \[
  Y' = \frac{C'rgba[G] \times (2^n-1) - 16 \times 2^n - 8}{219 \times 2^n - 8} \\
  C_B = \frac{C'rgba[B] \times (2^n-1) - 128 \times 2^n - 8}{224 \times 2^n - 8} \\
  C_R = \frac{C'rgba[R] \times (2^n-1) - 128 \times 2^n - 8}{224 \times 2^n - 8}
  \]

**Note**

These formulae correspond to the “narrow range” encoding in the “Quantization schemes” chapter of the Khronos Data Format Specification.
• \( n \) is the bit-depth of the channels in the format.

The precision of the operations performed during range expansion **must** be at least that of the source format.

An implementation **may** clamp the results of these range expansion operations such that \( Y' \) falls in the range \([0,1]\), and/or such that \( C_b \) and \( C_r \) fall in the range \([-0.5,0.5]\).

**Sampler \( Y'C_bC_r \) Model Conversion**

The range-expanded values are converted between color models, according to the color model conversion specified in the `ycbcrModel` member:

**VK_SAMPLER_YCBCR_MODEL_CONVERSION_RGB_IDENTITY**

The color channels are not modified by the color model conversion since they are assumed already to represent the desired color model in which the shader is operating; \( Y'C_bC_r \) range expansion is also ignored.

**VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_IDENTITY**

The color channels are not modified by the color model conversion and are assumed to be treated as though in \( Y'C_bC_r \) form both in memory and in the shader; \( Y'C_bC_r \) range expansion is applied to the channels as for other \( Y'C_bC_r \) models, with the vector \((C_r,Y',C_b,A)\) provided to the shader.

**VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_709**

The color channels are transformed from a \( Y'C_bC_r \) representation to an \( R'G'B' \) representation as described in the “BT.709 \( Y'C_bC_r \) conversion” section of the Khronos Data Format Specification.

**VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_601**

The color channels are transformed from a \( Y'C_bC_r \) representation to an \( R'G'B' \) representation as described in the “BT.601 \( Y'C_bC_r \) conversion” section of the Khronos Data Format Specification.

**VK_SAMPLER_YCBCR_MODEL_CONVERSION_YCBCR_2020**

The color channels are transformed from a \( Y'C_bC_r \) representation to an \( R'G'B' \) representation as described in the “BT.2020 \( Y'C_bC_r \) conversion” section of the Khronos Data Format Specification.

In this operation, each output channel is dependent on each input channel.

An implementation **may** clamp the \( R'G'B' \) results of these conversions to the range \([0,1]\).

The precision of the operations performed during model conversion **must** be at least that of the source format.

The alpha channel is not modified by these model conversions.
Note
Sampling operations in a non-linear color space can introduce color and intensity shifts at sharp transition boundaries. To avoid this issue, the technically precise color correction sequence described in the “Introduction to Color Conversions” chapter of the *Khronos Data Format Specification* may be performed as follows:

- Calculate the unnormalized texel coordinates corresponding to the desired sample position.
- For a minFilter or magFilter of VK_FILTER_NEAREST:
  1. Calculate \((i, j)\) for the sample location as described under the “nearest filtering” formulae in \((u, v, w, a)\) to \((i, j, k, l, n)\) Transformation And Array Layer Selection
  2. Calculate the normalized texel coordinates corresponding to these integer coordinates.
  3. Sample using sampler Y'C_bC_a conversion at this location.
- For a minFilter or magFilter of VK_FILTER_LINEAR:
  1. Calculate \((i_{0,1}, j_{0,1})\) for the sample location as described under the “linear filtering” formulae in \((u, v, w, a)\) to \((i, j, k, l, n)\) Transformation And Array Layer Selection
  2. Calculate the normalized texel coordinates corresponding to these integer coordinates.
  3. Sample using sampler Y'C_bC_a conversion at each of these locations.
  4. Convert the non-linear A'R'G'B' outputs of the Y'C_bC_a conversions to linear ARGB values as described in the “Transfer Functions” chapter of the *Khronos Data Format Specification*.
  5. Interpolate the linear ARGB values using the \(\alpha\) and \(\beta\) values described in the “linear filtering” section of \((u, v, w, a)\) to \((i, j, k, l, n)\) Transformation And Array Layer Selection and the equations in Texel Filtering.

The additional calculations and, especially, additional number of sampling operations in the VK_FILTER_LINEAR case can be expected to have a performance impact compared with using the outputs directly; since the variation from “correct” results are subtle for most content, the application author should determine whether a more costly implementation is strictly necessary. Note that if chromaFilter, and minFilter or magFilter are both VK_FILTER_NEAREST, these operations are redundant and sampling using sampler Y'C_bC_a conversion at the desired sample coordinates will produce the “correct” results without further processing.

15.4. Texel Output Operations

*Texel output instructions* are SPIR-V image instructions that write to an image. *Texel output operations* are a set of steps that are performed on state, coordinates, and texel values while
processing a texel output instruction, and which are common to some or all texel output instructions. They include the following steps, which are performed in the listed order:

- **Validation operations**
  - Format validation
  - Coordinate validation
  - Sparse validation
- **Texel output format conversion**

### 15.4.1. Texel Output Validation Operations

**Texel output validation operations** inspect instruction/image state or coordinates, and in certain circumstances cause the write to have no effect. There are a series of validations that the texel undergoes.

**Texel Format Validation**

If the image format of the `OpTypeImage` is not compatible with the `VkImageView`'s format, the write causes the contents of the image's memory to become undefined.

### 15.4.2. Integer Texel Coordinate Validation

The integer texel coordinates are validated according to the same rules as for texel input coordinate validation.

If the texel fails integer texel coordinate validation, then the write has no effect.

### 15.4.3. Sparse Texel Operation

If the texel attempts to write to an unbound region of a sparse image, the texel is a sparse unbound texel. In such a case, if the `VkPhysicalDeviceSparseProperties::residencyNonResidentStrict` property is `VK_TRUE`, the sparse unbound texel write has no effect. If `residencyNonResidentStrict` is `VK_FALSE`, the write may have a side effect that becomes visible to other accesses to unbound texels in any resource, but will not be visible to any device memory allocated by the application.

### 15.4.4. Texel Output Format Conversion

If the image format is sRGB, a linear to sRGB conversion is applied to the R, G, and B components as described in the “sRGB EOTF” section of the Khronos Data Format Specification. The A component, if present, is unchanged.

Texels then undergo a format conversion from the floating point, signed, or unsigned integer type of the texel data to the `VkFormat` of the image view. Any unused components are ignored.

Each component is converted based on its type and size (as defined in the Format Definition section for each `VkFormat`). Floating-point outputs are converted as described in Floating-Point Format Conversions and Fixed-Point Data Conversion. Integer outputs are converted such that their value is preserved. The converted value of any integer that cannot be represented in the target format is
15.5. Normalized Texel Coordinate Operations

If the image sampler instruction provides normalized texel coordinates, some of the following operations are performed.

15.5.1. Projection Operation

For Proj image operations, the normalized texel coordinates \((s,t,r,q,a)\) and (if present) the \(D_{ref}\) coordinate are transformed as follows:

\[
\begin{align*}
    s &= \frac{s}{q}, & \text{for 1D, 2D, or 3D image} \\
    t &= \frac{t}{q}, & \text{for 2D or 3D image} \\
    r &= \frac{r}{q}, & \text{for 3D image} \\
    D_{ref} &= \frac{D_{ref}}{q}, & \text{if provided}
\end{align*}
\]

15.5.2. Derivative Image Operations

Derivatives are used for LOD selection. These derivatives are either implicit (in an ImplicitLod image instruction in a fragment shader) or explicit (provided explicitly by shader to the image instruction in any shader).

For explicit derivatives image instructions, the derivatives of texel coordinates are calculated in the same manner as derivative operations. That is:

\[
\begin{align*}
    \frac{\partial s}{\partial x} &= dPdx(s), & \frac{\partial s}{\partial y} &= dPdy(s), & \text{for 1D, 2D, Cube, or 3D image} \\
    \frac{\partial t}{\partial x} &= dPdx(t), & \frac{\partial t}{\partial y} &= dPdy(t), & \text{for 2D, Cube, or 3D image} \\
    \frac{\partial u}{\partial x} &= dPdx(u), & \frac{\partial u}{\partial y} &= dPdy(u), & \text{for Cube or 3D image}
\end{align*}
\]

Partial derivatives not defined above for certain image dimensionalities are set to zero.

For explicit LOD image instructions, if the optional SPIR-V operand Grad is provided, then the operand values are used for the derivatives. The number of components present in each derivative for a given image dimensionality matches the number of partial derivatives computed above.

If the optional SPIR-V operand Lod is provided, then derivatives are set to zero, the cube map derivative transformation is skipped, and the scale factor operation is skipped. Instead, the floating point scalar coordinate is directly assigned to \(\lambda_{base}\) as described in Level-of-Detail Operation.

If the image or sampler object used by an implicit derivative image instruction is not uniform across the quad and quadDivergentImplicitLod is not supported, then the derivative and LOD values are undefined. Implicit derivatives are well-defined when the image and sampler and control flow are uniform across the quad, even if they diverge between different quads.

If quadDivergentImplicitLod is supported, then derivatives and implicit LOD values are well-defined even if the image or sampler object are not uniform within a quad. The derivatives are computed
as specified above, and the implicit LOD calculation proceeds for each shader invocation using its respective image and sampler object.

15.5.3. Cube Map Face Selection and Transformations

For cube map image instructions, the (s,t,r) coordinates are treated as a direction vector \((r_x, r_y, r_z)\). The direction vector is used to select a cube map face. The direction vector is transformed to a per-face texel coordinate system \((s_{face}, t_{face})\). The direction vector is also used to transform the derivatives to per-face derivatives.

15.5.4. Cube Map Face Selection

The direction vector selects one of the cube map’s faces based on the largest magnitude coordinate direction (the major axis direction). Since two or more coordinates can have identical magnitude, the implementation must have rules to disambiguate this situation.

The rules should have as the first rule that \(r_z\) wins over \(r_x\) and \(r_y\), and the second rule that \(r_y\) wins over \(r_z\). An implementation may choose other rules, but the rules must be deterministic and depend only on \((r_x, r_y, r_z)\).

The layer number (corresponding to a cube map face), the coordinate selections for \(s_c\), \(t_c\), \(r_c\), and the selection of derivatives, are determined by the major axis direction as specified in the following two tables.

**Table 25. Cube map face and coordinate selection**

Chapter 15. Image Operations | 815
15.5.5. Cube Map Coordinate Transformation

\[ s_{face} = \frac{1}{2} \times s_c \frac{1}{r_c} + \frac{1}{2} \]
\[ t_{face} = \frac{1}{2} \times t_c \frac{1}{r_c} + \frac{1}{2} \]

15.5.6. Cube Map Derivative Transformation

\[ \frac{\partial s_{face}}{\partial x} = \frac{\partial}{\partial x} \left( \frac{1}{2} \times s_c \frac{1}{r_c} + \frac{1}{2} \right) \]
\[ \frac{\partial s_{face}}{\partial x} = \frac{1}{2} \times \frac{\partial}{\partial x} \left( s_c \frac{1}{r_c} \right) \]
\[ \frac{\partial s_{face}}{\partial x} = \frac{1}{2} \times \left( \frac{r_c \times \partial s_c / \partial x - s_c \times \partial r_c / \partial x}{(r_c)^2} \right) \]
\[ \frac{\partial s_{face}}{\partial y} = \frac{1}{2} \times \left( \frac{r_c \times \partial s_c / \partial y - s_c \times \partial r_c / \partial y}{(r_c)^2} \right) \]
\[ \frac{\partial t_{face}}{\partial x} = \frac{1}{2} \times \left( \frac{r_c \times \partial t_c / \partial x - t_c \times \partial r_c / \partial x}{(r_c)^2} \right) \]
\[ \frac{\partial t_{face}}{\partial y} = \frac{1}{2} \times \left( \frac{r_c \times \partial t_c / \partial y - t_c \times \partial r_c / \partial y}{(r_c)^2} \right) \]

15.5.7. Scale Factor Operation, Level-of-Detail Operation and Image Level(s) Selection

LOD selection can be either explicit (provided explicitly by the image instruction) or implicit (determined from a scale factor calculated from the derivatives). The implicit LOD selected can be queried using the SPIR-V instruction OpImageQueryLod, which gives access to the \( \lambda \)' and \( d \) values, defined below. These values must be computed with mipmapPrecisionBits of accuracy and may be subject to implementation-specific maxima and minima for very large, out-of-range values.

Scale Factor Operation

The magnitude of the derivatives are calculated by:

\[ m_{ux} = |\partial s/\partial x| \times w_{base} \]
\[ m_{vx} = |\partial t/\partial x| \times h_{base} \]
\[ m_{wx} = |\partial r/\partial x| \times d_{base} \]

\[ m_{wy} = |\partial s/\partial y| \times w_{base} \]

\[ m_{vy} = |\partial t/\partial y| \times h_{base} \]

\[ m_{vy} = |\partial r/\partial y| \times d_{base} \]

where:

\[ \partial t/\partial x = \partial t/\partial y = 0 \] (for 1D images)

\[ \partial r/\partial x = \partial r/\partial y = 0 \] (for 1D, 2D or Cube images)

and:

\[ w_{base} = \text{image.w} \]

\[ h_{base} = \text{image.h} \]

\[ d_{base} = \text{image.d} \]

(for the baseMipLevel, from the image descriptor).

For corner-sampled images, the \( w_{base} \), \( h_{base} \), and \( d_{base} \) are instead:

\[ w_{base} = \text{image.w} - 1 \]

\[ h_{base} = \text{image.h} - 1 \]

\[ d_{base} = \text{image.d} - 1 \]

A point sampled in screen space has an elliptical footprint in texture space. The minimum and maximum scale factors (\( \rho_{\text{min}}, \rho_{\text{max}} \)) should be the minor and major axes of this ellipse.

The scale factors \( \rho_x \) and \( \rho_y \), calculated from the magnitude of the derivatives in x and y, are used to compute the minimum and maximum scale factors.
\( \rho_x \) and \( \rho_y \) may be approximated with functions \( f_x \) and \( f_y \), subject to the following constraints:

- \( f_x \) is continuous and monotonically increasing in each of \( m_{ux}, m_{vx}, \) and \( m_{wx} \)
- \( f_y \) is continuous and monotonically increasing in each of \( m_{uy}, m_{vy}, \) and \( m_{wy} \)

\[
\max(|m_{ux}|, |m_{vx}|, |m_{wx}|) \leq f_x \leq \sqrt[2]{|m_{ux}| + |m_{vx}| + |m_{wx}|} \\
\max(|m_{uy}|, |m_{vy}|, |m_{wy}|) \leq f_y \leq \sqrt[2]{|m_{uy}| + |m_{vy}| + |m_{wy}|}
\]

The minimum and maximum scale factors (\( \rho_{\text{min}}, \rho_{\text{max}} \)) are determined by:

\[
\rho_{\text{max}} = \max(\rho_x, \rho_y) \\
\rho_{\text{min}} = \min(\rho_x, \rho_y)
\]

The ratio of anisotropy is determined by:

\[
\eta = \min(\rho_{\text{max}}/\rho_{\text{min}}, \text{maxAniso})
\]

where:

- \( \text{maxAniso} = \text{maxAnisotropy} \) (from sampler descriptor)
- \( \text{maxSamplerAnisotropy} \) (from physical device limits)

\[
\text{maxAniso} = \min(\text{maxAniso}, \text{maxSamplerAnisotropy})
\]

If \( \rho_{\text{max}} = \rho_{\text{min}} = 0 \), then all the partial derivatives are zero, the fragment's footprint in texel space is a point, and \( N \) should be treated as 1. If \( \rho_{\text{max}} \neq 0 \) and \( \rho_{\text{min}} = 0 \) then all partial derivatives along one axis are zero, the fragment's footprint in texel space is a line segment, and \( \eta \) should be treated as \( \text{maxAniso} \). However, anytime the footprint is small in texel space the implementation may use a smaller value of \( \eta \), even when \( \rho_{\text{min}} \) is zero or close to zero. If either \( \text{VkPhysicalDeviceFeatures}::\text{samplerAnisotropy} \) or \( \text{VkSamplerCreateInfo}::\text{anisotropyEnable} \) are \( \text{VK_FALSE} \), \( \text{maxAniso} \) is set to 1.

If \( \eta = 1 \), sampling is isotropic. If \( \eta > 1 \), sampling is anisotropic.

The sampling rate (\( N \)) is derived as:

\[
N = \lceil \eta \rceil
\]

An implementation may round \( N \) up to the nearest supported sampling rate. An implementation may use the value of \( N \) as an approximation of \( \eta \).
Level-of-Detail Operation

The LOD parameter $\lambda$ is computed as follows:

$$\lambda_{\text{base}}(x, y) = \begin{cases} \text{shaderOp.Lod} & \text{(from optional SPIR-V operand)} \\ \log_{2} \left( \frac{\rho_{\max}}{\eta} \right) & \text{otherwise} \end{cases}$$

$$\lambda'(x, y) = \lambda_{\text{base}} + \text{clamp}(\text{sampler.bias + shaderOp.bias, } -\max\text{SamplerLodBias}, \max\text{SamplerLodBias})$$

$$\lambda = \begin{cases} \text{lod}_{\max}, & \lambda' > \text{lod}_{\max} \\ \lambda', & \text{lod}_{\min} \leq \lambda' \leq \text{lod}_{\max} \\ \text{lod}_{\min}, & \lambda' < \text{lod}_{\min} \\ \text{undefined}, & \text{lod}_{\min} > \text{lod}_{\max} \end{cases}$$

where:

$$\text{sampler.bias} = \text{mipLodBias} \quad \text{(from sampler descriptor)}$$

$$\text{shaderOp.bias} = \begin{cases} \text{Bias} & \text{(from optional SPIR-V operand)} \\ \text{0} & \text{otherwise} \end{cases}$$

$$\text{sampler.lod}_{\min} = \text{minLod} \quad \text{(from sampler descriptor)}$$

$$\text{shaderOp.lod}_{\min} = \begin{cases} \text{MinLod} & \text{(from optional SPIR-V operand)} \\ \text{0} & \text{otherwise} \end{cases}$$

$$\text{lod}_{\min} = \max(\text{sampler.lod}_{\min}, \text{shaderOp.lod}_{\min})$$

$$\text{lod}_{\max} = \max\text{Lod} \quad \text{(from sampler descriptor)}$$

and $\max\text{SamplerLodBias}$ is the value of the VkPhysicalDeviceLimits feature $\max\text{SamplerLodBias}$.

Image Level(s) Selection

The image level(s) $d$, $d_{hi}$, and $d_{lo}$, which texels are read from are determined by an image-level parameter $d_l$, which is computed based on the LOD parameter, as follows:

$$d_l = \begin{cases} \text{nearest}(d'), & \text{mipmapMode is VK_SAMPLER_MIPMAP_MODE_NEAREST} \\ d' & \text{otherwise} \end{cases}$$

where:

$$d' = \text{level}_{\text{base}} + \text{clamp}(\lambda, 0, q)$$

$$\text{nearest}(d') = \begin{cases} \lfloor d' + 0.5 \rfloor - 1, & \text{preferred} \\ \lfloor d' + 0.5 \rfloor, & \text{alternative} \end{cases}$$

and:

$$\text{level}_{\text{base}} = \text{baseMipLevel}$$

$$q = \text{levelCount} - 1$$

$\text{baseMipLevel}$ and $\text{levelCount}$ are taken from the subresourceRange of the image view.

If the sampler’s mipmapMode is VK_SAMPLER_MIPMAP_MODE_NEAREST, then the level selected is $d = d_l$. 
If the sampler’s `mipmapMode` is `VK_SAMPLER_MIPMAP_MODE_LINEAR`, two neighboring levels are selected:

\[
\begin{align*}
\delta_n &= \lfloor d_i \rfloor \\
\delta_o &= \min(d_n + 1, q) \\
\delta &= d_i - d_n
\end{align*}
\]

\(\delta\) is the fractional value, quantized to the number of mipmap precision bits, used for linear filtering between levels.

### 15.5.8. \((s,t,r,q,a)\) to \((u,v,w,a)\) Transformation

The normalized texel coordinates are scaled by the image level dimensions and the array layer is selected.

This transformation is performed once for each level used in filtering (either \(d\), or \(d_{hi}\) and \(d_{lo}\)).

\[
\begin{align*}
u(x, y) &= s(x, y) \times width_{scale} + \Delta_i \\
v(x, y) &= \begin{cases} 0 & \text{for 1D images} \\
(t(x, y) \times height_{scale} + \Delta_j) & \text{otherwise}
\end{cases} \\
w(x, y) &= \begin{cases} 0 & \text{for 2D or Cube images} \\
r(x, y) \times depth_{scale} + \Delta_k & \text{otherwise}
\end{cases} \\
a(x, y) &= \begin{cases} a(x, y) & \text{for array images} \\
0 & \text{otherwise}
\end{cases}
\end{align*}
\]

where:

\[
\begin{align*}
width_{scale} &= width_{level} \\
height_{scale} &= height_{level} \\
depth_{scale} &= depth_{level}
\end{align*}
\]

for conventional images, and:

\[
\begin{align*}
width_{scale} &= width_{level} - 1 \\
height_{scale} &= height_{level} - 1 \\
depth_{scale} &= depth_{level} - 1
\end{align*}
\]

for corner-sampled images.

and where \((\Delta_i, \Delta_j, \Delta_k)\) are taken from the image instruction if it includes a `ConstOffset` or `Offset` operand, otherwise they are taken to be zero.
Operations then proceed to Unnormalized Texel Coordinate Operations.

15.6. Unnormalized Texel Coordinate Operations

15.6.1. (u,v,w,a) to (i,j,k,l,n) Transformation And Array Layer Selection

The unnormalized texel coordinates are transformed to integer texel coordinates relative to the selected mipmap level.

The layer index l is computed as:

\[ l = \text{clamp}(\text{RNE}(a), 0, \text{layerCount} - 1) + \text{baseArrayLayer} \]

where \( \text{layerCount} \) is the number of layers in the image subresource range of the image view, \( \text{baseArrayLayer} \) is the first layer from the subresource range, and where:

\[ \text{RNE}(a) = \begin{cases} \text{roundTiesToEven}(a) & \text{preferred, from IEEE Std 754-2008 Floating-Point Arithmetic} \\ a + 0.5 & \text{alternative} \end{cases} \]

The sample index \( n \) is assigned the value 0.

Nearest filtering (VK_FILTER_NEAREST) computes the integer texel coordinates that the unnormalized coordinates lie within:

\[
\begin{align*}
i &= \lfloor u + \text{shift} \rfloor \\
j &= \lfloor v + \text{shift} \rfloor \\
k &= \lfloor w + \text{shift} \rfloor
\end{align*}
\]

where:

\[ \text{shift} = 0.0 \]

for conventional images, and:

\[ \text{shift} = 0.5 \]

for corner-sampled images.

Linear filtering (VK_FILTER_LINEAR) computes a set of neighboring coordinates which bound the unnormalized coordinates. The integer texel coordinates are combinations of \( i_0 \) or \( i_1 \), \( j_0 \) or \( j_1 \), \( k_0 \) or \( k_1 \), as well as weights \( \alpha \), \( \beta \), and \( \gamma \).

\[
\begin{align*}
i_0 &= \lfloor u - \text{shift} \rfloor \\
i_1 &= i_0 + 1 \\
j_0 &= \lfloor v - \text{shift} \rfloor \\
j_1 &= j_0 + 1 \\
k_0 &= \lfloor w - \text{shift} \rfloor, k_1 = k_0 + 1
\end{align*}
\]
\[
\alpha = \text{frac}(u - \text{shift}) \\
\beta = \text{frac}(v - \text{shift}) \\
\gamma = \text{frac}(w - \text{shift})
\]

where:

shift = 0.5

for conventional images, and:

shift = 0.0

for corner-sampled images, and where:

\[
\text{frac}(x) = x - \lfloor x \rfloor
\]

where the number of fraction bits retained is specified by `VkPhysicalDeviceLimits::subTexelPrecisionBits`.

Cubic filtering (VK_FILTER_CUBIC_EXT) computes a set of neighboring coordinates which bound the unnormalized coordinates. The integer texel coordinates are combinations of \(i_0, i_1, i_2\) or \(i_3\), \(j_0, j_1, j_2\) or \(j_3\), \(k_0, k_1, k_2\) or \(k_3\), as well as weights \(\alpha, \beta,\) and \(\gamma\).

\[
\begin{align*}
\alpha &= \text{frac}(u - \frac{3}{2}) \\
\beta &= \text{frac}(v - \frac{3}{2}) \\
\gamma &= \text{frac}(w - \frac{3}{2})
\end{align*}
\]

where:

\[
\text{frac}(x) = x - \lfloor x \rfloor
\]

where the number of fraction bits retained is specified by `VkPhysicalDeviceLimits::subTexelPrecisionBits`.

### 15.7. Integer Texel Coordinate Operations

Integer texel coordinate operations may supply a LOD which texels are to be read from or written to using the optional SPIR-V operand `Lod`. If the `Lod` is provided then it must be an integer.
The image level selected is:

\[
d = \text{level}_{\text{base}} + \begin{cases} 
Lod & \text{(from optional SPIR-V operand)} \\
0 & \text{otherwise}
\end{cases}
\]

If \(d\) does not lie in the range \([\text{baseMipLevel}, \text{baseMipLevel} + \text{levelCount}]\) then any values fetched are zero if \text{robustImageAccess2} \ is enabled, otherwise are undefined, and any writes (if supported) are discarded.

15.8. Image Sample Operations

15.8.1. Wrapping Operation

\text{Cube} images ignore the wrap modes specified in the sampler. Instead, if \text{VK_FILTER_NEAREST} is used within a mip level then \text{VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE} is used, and if \text{VK_FILTER_LINEAR} is used within a mip level then sampling at the edges is performed as described earlier in the \text{Cube map edge handling} section.

The first integer texel coordinate \(i\) is transformed based on the \text{addressModeU} parameter of the sampler.

\[
i = \begin{cases} 
i \mod \text{size} & \text{for repeat} \\
(\text{size} - 1) - \text{mirror} \left( (i \mod (2 \times \text{size})) - \text{size} \right) & \text{for mirrored repeat} \\
\text{clamp} (i, 0, \text{size} - 1) & \text{for clamp to edge} \\
\text{clamp} (i, -1, \text{size}) & \text{for clamp to border} \\
\text{clamp} \left( \text{mirror} (i), 0, \text{size} - 1 \right) & \text{for mirror clamp to edge}
\end{cases}
\]

where:

\[
mirror (n) = \begin{cases} 
n & \text{for } n \geq 0 \\
-1 - n & \text{otherwise}
\end{cases}
\]

\(j\) (for 2D and \text{Cube} image) and \(k\) (for 3D image) are similarly transformed based on the \text{addressModeV} and \text{addressModeW} parameters of the sampler, respectively.

15.8.2. Texel Gathering

SPIR-V instructions with \text{Gather} in the name return a vector derived from 4 texels in the base level of the image view. The rules for the \text{VK_FILTER_LINEAR} minification filter are applied to identify the four selected texels. Each texel is then converted to an RGBA value according to conversion to RGBA and then swizzled. A four-component vector is then assembled by taking the component indicated by the \text{Component} value in the instruction from the swizzled color value of the four texels. If the operation does not use the \text{ConstOffsets} image operand then the four texels form the \(2 \times 2\) rectangle used for texture filtering:

\[
\tau[R] = \tau[i_{0j_{0}}][\text{level}_{\text{base}}][\text{comp}]
\]

\[
\tau[G] = \tau[i_{0j_{1}}][\text{level}_{\text{base}}][\text{comp}]
\]

\[
\tau[B] = \tau[i_{1j_{0}}][\text{level}_{\text{base}}][\text{comp}]
\]

\[
\tau[A] = \tau[i_{1j_{1}}][\text{level}_{\text{base}}][\text{comp}]
\]
If the operation does use the `ConstOffsets` image operand then the offsets allow a custom filter to be defined:

$$\tau[R] = \tau_{ij} + \Delta_x[\text{level}]_{\text{comp}}$$
$$\tau[G] = \tau_{ij} + \Delta_y[\text{level}]_{\text{comp}}$$
$$\tau[B] = \tau_{ij} + \Delta_z[\text{level}]_{\text{comp}}$$
$$\tau[A] = \tau_{ij} + \Delta_4[\text{level}]_{\text{comp}}$$

where:

$$\tau[\text{level}]_{\text{comp}} = \begin{cases} 
\tau[\text{level}]_{\text{R}}, & \text{for } \text{comp} = 0 \\
\tau[\text{level}]_{\text{G}}, & \text{for } \text{comp} = 1 \\
\tau[\text{level}]_{\text{B}}, & \text{for } \text{comp} = 2 \\
\tau[\text{level}]_{\text{A}}, & \text{for } \text{comp} = 3 
\end{cases}$$

`OpImage*Gather` must not be used on a sampled image with `sampler Y’C9C9` conversion enabled.

### 15.8.3. Texel Filtering

Texel filtering is first performed for each level (either `d` or `d_hi` and `d_lo`).

If $\lambda$ is less than or equal to zero, the texture is said to be **magnified**, and the filter mode within a mip level is selected by the `magFilter` in the sampler. If $\lambda$ is greater than zero, the texture is said to be **minified**, and the filter mode within a mip level is selected by the `minFilter` in the sampler.

#### Texel Nearest Filtering

Within a mip level, `VK_FILTER_NEAREST` filtering selects a single value using the (i, j, k) texel coordinates, with all texels taken from layer l.

$$\tau[\text{level}] = \begin{cases} 
\tau_{ijl}[\text{level}]., & \text{for 3D image} \\
\tau_{ljl}[\text{level}]., & \text{for 2D or Cube image} \\
\tau_{li}[\text{level}]., & \text{for 1D image} 
\end{cases}$$

#### Texel Linear Filtering

Within a mip level, `VK_FILTER_LINEAR` filtering combines 8 (for 3D), 4 (for 2D or Cube), or 2 (for 1D) texel values, together with their linear weights. The linear weights are derived from the fractions computed earlier:

$$w_{i0} = (1 - \alpha)$$
$$w_{i1} = \alpha$$
$$w_{j0} = (1 - \beta)$$
$$w_{j1} = \beta$$
$$w_{k0} = (1 - \gamma)$$
$$w_{k1} = \gamma$$

The values of multiple texels, together with their weights, are combined to produce a filtered value.

The `VkSamplerReductionModeCreateInfo::reductionMode` can control the process by which multiple
texels, together with their weights, are combined to produce a filtered texture value.

When the `reductionMode` is set (explicitly or implicitly) to `VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE`, a weighted average is computed:

\[
\tau_{3D} = \sum_{k=k_0}^{k_1} \sum_{j=j_0}^{j_1} \sum_{l=l_0}^{l_1} (w_j)(w_k)\tau_{ijk}
\]
\[
\tau_{2D} = \sum_{j=j_0}^{j_1} \sum_{l=l_0}^{l_1} (w_j)\tau_{ij}
\]
\[
\tau_{1D} = \sum_{l=l_0}^{l_1} (w_l)\tau_{i}
\]

However, if the reduction mode is `VK_SAMPLER_REDUCTION_MODE_MIN` or `VK_SAMPLER_REDUCTION_MODE_MAX`, the process operates on the above set of multiple texels, together with their weights, computing a component-wise minimum or maximum, respectively, of the components of the set of texels with non-zero weights.

**Texel Cubic Filtering**

Within a mip level, `VK_FILTER_CUBIC_EXT`, filtering computes a weighted average of 64 (for 3D), 16 (for 2D), or 4 (for 1D) texel values, together with their Catmull-Rom weights.

Catmull-Rom weights are derived from the fractions computed earlier.

\[
\begin{bmatrix}
  w_{i_0} & w_{i_1} & w_{i_2} & w_{i_3} \\
\end{bmatrix} = \frac{1}{2} \begin{bmatrix}
  1 & \alpha & \alpha^2 & \alpha^3 \\
\end{bmatrix} \begin{bmatrix}
  0 & 2 & 0 & 0 \\
  -1 & 0 & 1 & 0 \\
  -2 & -5 & 4 & -1 \\
  -1 & 3 & -3 & 1 \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
  w_{j_0} & w_{j_1} & w_{j_2} & w_{j_3} \\
\end{bmatrix} = \frac{1}{2} \begin{bmatrix}
  1 & \beta & \beta^2 & \beta^3 \\
\end{bmatrix} \begin{bmatrix}
  0 & 2 & 0 & 0 \\
  -1 & 0 & 1 & 0 \\
  -2 & -5 & 4 & -1 \\
  -1 & 3 & -3 & 1 \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
  w_{k_0} & w_{k_1} & w_{k_2} & w_{k_3} \\
\end{bmatrix} = \frac{1}{2} \begin{bmatrix}
  1 & \gamma & \gamma^2 & \gamma^3 \\
\end{bmatrix} \begin{bmatrix}
  0 & 2 & 0 & 0 \\
  -1 & 0 & 1 & 0 \\
  -2 & -5 & 4 & -1 \\
  -1 & 3 & -3 & 1 \\
\end{bmatrix}
\]

The values of multiple texels, together with their weights, are combined to produce a filtered value.

The `VkSamplerReductionModeCreateInfo::reductionMode` can control the process by which multiple texels, together with their weights, are combined to produce a filtered texture value.

When the `reductionMode` is set (explicitly or implicitly) to `VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE`, a weighted average is computed:

\[
\tau_{3D} = \sum_{k=k_0}^{k_1} \sum_{j=j_0}^{j_1} \sum_{l=l_0}^{l_1} (w_j)(w_k)\tau_{ijk}
\]
\[
\tau_{2D} = \sum_{j=j_0}^{j_1} \sum_{l=l_0}^{l_1} (w_j)\tau_{ij}
\]
\[
\tau_{1D} = \sum_{l=l_0}^{l_1} (w_l)\tau_{i}
\]
However, if the reduction mode is `VK_SAMPLER_REDUCTION_MODE_MIN` or `VK_SAMPLER_REDUCTION_MODE_MAX`, the process operates on the above set of multiple texels, together with their weights, computing a component-wise minimum or maximum, respectively, of the components of the set of texels with non-zero weights.

**Texel Mipmap Filtering**

`VK_SAMPLER_MIPMAP_MODE_NEAREST` filtering returns the value of a single mipmap level, 
\[ \tau = \tau[d]. \]

`VK_SAMPLER_MIPMAP_MODE_LINEAR` filtering combines the values of multiple mipmap levels (\(\tau[\text{hi}]\) and \(\tau[\text{lo}]\)), together with their linear weights.

The linear weights are derived from the fraction computed earlier:

\[
\begin{align*}
    w_{\text{hi}} &= (1 - \delta) \\
    w_{\text{lo}} &= (\delta)
\end{align*}
\]

The values of multiple mipmap levels, together with their weights, are combined to produce a final filtered value.

The `VkSamplerReductionModeCreateInfo::reductionMode` can control the process by which multiple texels, together with their weights, are combined to produce a filtered texture value.

When the `reductionMode` is set (explicitly or implicitly) to `VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE`, a weighted average is computed:

\[
\tau = (w_{\text{hi}})\tau[\text{hi}] + (w_{\text{lo}})\tau[\text{lo}]
\]

**Texel Anisotropic Filtering**

Anisotropic filtering is enabled by the `anisotropyEnable` in the sampler. When enabled, the image filtering scheme accounts for a degree of anisotropy.

The particular scheme for anisotropic texture filtering is implementation dependent. Implementations should consider the `magFilter`, `minFilter` and `mipmapMode` of the sampler to control the specifics of the anisotropic filtering scheme used. In addition, implementations should consider `minLod` and `maxLod` of the sampler.

The following describes one particular approach to implementing anisotropic filtering for the 2D Image case, implementations may choose other methods:

Given a `magFilter`, `minFilter` of `VK_FILTER_LINEAR` and a `mipmapMode` of `VK_SAMPLER_MIPMAP_MODE_NEAREST`:

Instead of a single isotropic sample, \(N\) isotropic samples are be sampled within the image footprint of the image level \(d\) to approximate an anisotropic filter. The sum \(\tau_{2D\text{aniso}}\) is defined using the single isotropic \(\tau_{2D}(u,v)\) at level \(d\).
When `VkSamplerReductionModeCreateInfo::reductionMode` is set to `VK_SAMPLER_REDUCTION_MODE_WEIGHTED_AVERAGE`, the above summation is used. However, if the reduction mode is `VK_SAMPLER_REDUCTION_MODE_MIN` or `VK_SAMPLER_REDUCTION_MODE_MAX`, the process operates on the above values, together with their weights, computing a component-wise minimum or maximum, respectively, of the components of the values with non-zero weights.

15.9. Texel Footprint Evaluation

The SPIR-V instruction `OpImageSampleFootprintNV` evaluates the set of texels from a single mip level that would be accessed during a texel filtering operation. In addition to the inputs that would be accepted by an equivalent `OpImageSample*` instruction, `OpImageSampleFootprintNV` accepts two additional inputs. The `Granularity` input is an integer identifying the size of texel groups used to evaluate the footprint. Each bit in the returned footprint mask corresponds to an aligned block of texels whose size is given by the following table:

<table>
<thead>
<tr>
<th>Granularity</th>
<th>Dim = 2D</th>
<th>Dim = 3D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>unsupported</td>
<td>unsupported</td>
</tr>
<tr>
<td>1</td>
<td>2x2</td>
<td>2x2x2</td>
</tr>
<tr>
<td>2</td>
<td>4x2</td>
<td>unsupported</td>
</tr>
<tr>
<td>3</td>
<td>4x4</td>
<td>4x4x2</td>
</tr>
<tr>
<td>4</td>
<td>8x4</td>

<tr>
<td>14</td>
<td>256x128</td>
<td>64x32x32</td>
</tr>
<tr>
<td>15</td>
<td>256x256</td>
<td>unsupported</td>
</tr>
</tbody>
</table>

The `Coarse` input is used to select between the two mip levels that may be accessed during texel filtering when using a `mipmapMode` of `VK_SAMPLER_MIPMAP_MODE_LINEAR`. When filtering between two
mip levels, a **Coarse** value of **true** requests the footprint in the lower-resolution mip level (higher level number), while **false** requests the footprint in the higher-resolution mip level. If texel filtering would access only a single mip level, the footprint in that level would be returned when **Coarse** is set to **false**; an empty footprint would be returned when **Coarse** is set to **true**.

The footprint for **OpImageSampleFootprintNV** is returned in a structure with six members:

- The first member is a boolean value that is true if the texel filtering operation would access only a single mip level.
- The second member is a two- or three-component integer vector holding the footprint anchor location. For two-dimensional images, the returned components are in units of eight texel groups. For three-dimensional images, the returned components are in units of four texel groups.
- The third member is a two- or three-component integer vector holding a footprint offset relative to the anchor. All returned components are in units of texel groups.
- The fourth member is a two-component integer vector mask, which holds a bitfield identifying the set of texel groups in an 8x8 or 4x4x4 neighborhood relative to the anchor and offset.
- The fifth member is an integer identifying the mip level containing the footprint identified by the anchor, offset, and mask.
- The sixth member is an integer identifying the granularity of the returned footprint.

For footprints in two-dimensional images (**Dim2D**), the mask returned by **OpImageSampleFootprintNV** indicates whether each texel group in a 8x8 local neighborhood of texel groups would have one or more texels accessed during texel filtering. In the mask, the texel group with local group coordinates (**lgx**, **lgy**) is considered covered if and only if

\[
0 \neq ((\text{mask}.x + (\text{mask}.y<<32))\&(1<<(\text{lgx} \times 8 + \text{lgy})))
\]

where:

- \(0\leq lgx<8\) and \(0\leq lgy<8\); and
- **mask** is the returned two-component mask.

The local group with coordinates (**lgx**, **lgy**) in the mask is considered covered if and only if the texel filtering operation would access one or more texels in the returned miplevel where:

\[
i0 = \begin{cases} 
  \text{gran}.x \times (8 \times \text{anchor}.x + \text{lgy}) , & \text{if } lgx + offset.x < 8 \\
  \text{gran}.x \times (8 \times (\text{anchor}.x - 1) + \text{lgy}) , & \text{otherwise}
\end{cases}
\]

\[
i1 = i0 + \text{gran}.x - 1
\]

\[
j0 = \begin{cases} 
  \text{gran}.y \times (8 \times \text{anchor}.y + \text{lgx}) , & \text{if } lgy + offset.y < 8 \\
  \text{gran}.y \times (8 \times (\text{anchor}.y - 1) + \text{lgx}) , & \text{otherwise}
\end{cases}
\]

\[
j1 = j0 + \text{gran}.y - 1
\]

and

- \(i0\leq i\leq i1\) and \(j0\leq j\leq j1\);
- **gran** is a two-component vector holding the width and height of the texel group identified by the granularity;
• anchor is the returned two-component anchor vector; and
• offset is the returned two-component offset vector.

For footprints in three-dimensional images (Dim3D), the mask returned by \texttt{OpImageSampleFootprintNV} indicates whether each texel group in a 4x4x4 local neighborhood of texel groups would have one or more texels accessed during texel filtering. In the mask, the texel group with local group coordinates \((l_{gx}, l_{gy}, l_{gz})\), is considered covered if and only if:

\[
0 \neq ((\text{mask}.x + (\text{mask}.y<<32))&(1<<(l_{gz} \times 16 + l_{gy} \times 4 + l_{gx})))
\]

where:

• \(0\leq l_{gx}<4, 0\leq l_{gy}<4, \text{ and } 0\leq l_{gz}<4; \) and
• mask is the returned two-component mask.

The local group with coordinates \((l_{gx}, l_{gy}, l_{gz})\) in the mask is considered covered if and only if the texel filtering operation would access one or more texels \(t_{ijk}\) in the returned miplevel where:

\[
i0 = \begin{cases} 
\text{gran}.x \times (4 \times \text{anchor}.x + l_{gx}), & \text{if} \ l_{gx} + \text{offset}.x < 4 \\
\text{gran}.x \times (4 \times (\text{anchor}.x - 1) + l_{gx}), & \text{otherwise}
\end{cases} \\
i1 = i0 + \text{gran}.x - 1 \\
j0 = \begin{cases} 
\text{gran}.y \times (4 \times \text{anchor}.y + l_{gy}), & \text{if} \ l_{gy} + \text{offset}.y < 4 \\
\text{gran}.y \times (4 \times (\text{anchor}.y - 1) + l_{gy}), & \text{otherwise}
\end{cases} \\
j1 = j0 + \text{gran}.y - 1 \\
k0 = \begin{cases} 
\text{gran}.z \times (4 \times \text{anchor}.z + l_{gz}), & \text{if} \ l_{gz} + \text{offset}.z < 4 \\
\text{gran}.z \times (4 \times (\text{anchor}.z - 1) + l_{gz}), & \text{otherwise}
\end{cases} \\
k1 = k0 + \text{gran}.z - 1
\]

and

• \(i0\leq i\leq i1, j0\leq j\leq j1, k0\leq k\leq k1; \)
• gran is a three-component vector holding the width, height, and depth of the texel group identified by the granularity;
• anchor is the returned three-component anchor vector; and
• offset is the returned three-component offset vector.

If the sampler used by \texttt{OpImageSampleFootprintNV} enables anisotropic texel filtering via \texttt{anisotropyEnable}, it is possible that the set of texel groups accessed in a mip level may be too large to be expressed using an 8x8 or 4x4x4 mask using the granularity requested in the instruction. In this case, the implementation uses a texel group larger than the requested granularity. When a larger texel group size is used, \texttt{OpImageSampleFootprintNV} returns an integer granularity value that can be interpreted in the same manner as the granularity value provided to the instruction to determine the texel group size used. If anisotropic texel filtering is disabled in the sampler, or if an anisotropic footprint can be represented as an 8x8 or 4x4x4 mask with the requested granularity, \texttt{OpImageSampleFootprintNV} will use the requested granularity as-is and return a granularity value of zero.

\texttt{OpImageSampleFootprintNV} supports only two- and three-dimensional image accesses (Dim2D and Dim3D) and the footprint returned is undefined if a sampler uses an addressing mode other than
15.10. Image Operation Steps

Each step described in this chapter is performed by a subset of the image instructions:

- Texel Input Validation Operations, Format Conversion, Texel Replacement, Conversion to RGBA, and Component Swizzle: Performed by all instructions except OpImageWrite.
- Depth Comparison: Performed by OpImage*Dref instructions.
- All Texel output operations: Performed by OpImageWrite.
- Projection: Performed by all OpImage*Proj instructions.
- Derivative Image Operations, Cube Map Operations, Scale Factor Operation, Level-of-Detail Operation and Image Level(s) Selection, and Texel Anisotropic Filtering: Performed by all OpImageSample* and OpImageSparseSample* instructions.
- (s,t,r,q,a) to (u,v,w,a) Transformation, Wrapping, and (u,v,w,a) to (i,j,k,l,n) Transformation And Array Layer Selection: Performed by all OpImageSample, OpImageSparseSample, and OpImage*Gather instructions.
- Texel Filtering: Performed by all OpImageSample* and OpImageSparseSample* instructions.
- Sparse Residency: Performed by all OpImageSparse* instructions.
Chapter 16. Fragment Density Map Operations

16.1. Fragment Density Map Operations Overview

When a fragment is generated in a render pass that has a fragment density map attachment, its area is determined by the properties of the local framebuffer region that the fragment occupies. The framebuffer is divided into a uniform grid of these local regions, and their fragment area property is derived from the density map with the following operations:

- Fetch density value
  - Component swizzle
  - Component mapping
- Fragment area conversion
  - Fragment area filter
  - Fragment area clamp

16.2. Fetch Density Value

Each local framebuffer region at center coordinate (x,y) fetches a texel from the fragment density map at integer coordinates:

\[ i = \left\lfloor \frac{x}{\text{FragmentDensityTexelSize}_{\text{width}}} \right\rfloor \]

\[ j = \left\lfloor \frac{y}{\text{FragmentDensityTexelSize}_{\text{height}}} \right\rfloor \]

Where the size of each region in the framebuffer is:

\[ \text{fragmentDensityTexelSize}_{\text{width}} = 2^\left(\left\lfloor \log_2\left(\frac{\text{bufferWidth}}{\text{FragmentDensityMapWidth}}\right)\right\rfloor\right) \]

\[ \text{fragmentDensityTexelSize}_{\text{height}} = 2^\left(\left\lfloor \log_2\left(\frac{\text{bufferHeight}}{\text{FragmentDensityMapHeight}}\right)\right\rfloor\right) \]

This region is subject to the limits in \text{VkPhysicalDeviceFragmentDensityMapPropertiesEXT} and therefore the final region size is clamped:

\[ \text{fragmentDensityTexelSize}_{\text{width}} = \text{clamp} (\text{fragmentDensityTexelSize}_{\text{width}}, \text{minFragmentDensityTexelSize}_{\text{width}}, \text{maxFragmentDensityTexelSize}_{\text{width}}) \]
When multiview is enabled for the render pass and the fragment density map attachment view was created with `layerCount` greater than 1, the density map layer that the texel is fetched from is:

\[
layer = baseArrayLayer + ViewIndex
\]

Otherwise:

\[
layer = baseArrayLayer
\]

The texel fetched from the density map at (i,j,layer) is next converted to density with the following operations.

### 16.2.1. Component Swizzle

The `components` member of `VkImageViewCreateInfo` is applied to the fetched texel as defined in Image component swizzle.

### 16.2.2. Component Mapping

The swizzled texel's components are mapped to a density value:

\[
densityValue_{xy} = (C^{r}, C^{g})
\]

### 16.3. Fragment Area Conversion

Fragment area for the framebuffer region is undefined if the density fetched is not a normalized floating-point value greater than 0.0. Otherwise, the fetched fragment area for that region is derived as:

\[
fragmentArea_{wh} = \frac{1.0}{densityValue_{xy}}
\]

#### 16.3.1. Fragment Area Filter

Optionally, the implementation may fetch additional density map texels in an implementation defined window around (i,j). The texels follow the standard conversion steps up to and including fragment area conversion.

A single fetched fragment area for the framebuffer region is chosen by the implementation and must have an area between the min and max areas of the fetched set.
16.3.2. Fragment Area Clamp

The implementation may clamp the fetched fragment area to one that it supports. The clamped fragment area must have a size less than or equal to the original fetched value. Implementations may vary the supported set of fragment areas per framebuffer region. Fragment area (1,1) must always be in the supported set.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>
For example, if the fetched fragment area is (1,4) but the implementation only supports areas of {(1,1),(2,2)}, it could choose to clamp the area to (2,2) since it has the same size as (1,4). While this would produce fragments that have lower quality strictly in the x-axis, the overall density is maintained.

The clamped fragment area is assigned to the corresponding framebuffer region.
Chapter 17. Queries

Queries provide a mechanism to return information about the processing of a sequence of Vulkan commands. Query operations are asynchronous, and as such, their results are not returned immediately. Instead, their results, and their availability status are stored in a Query Pool. The state of these queries can be read back on the host, or copied to a buffer object on the device.

The supported query types are Occlusion Queries, Pipeline Statistics Queries, and Timestamp Queries. Performance Queries are also supported if the associated extension is available. Intel performance queries are also supported if the associated extension is available.

17.1. Query Pools

Queries are managed using query pool objects. Each query pool is a collection of a specific number of queries of a particular type.

Query pools are represented by VkQueryPool handles:

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkQueryPool)
```

To create a query pool, call:

```c
VkResult vkCreateQueryPool(
    VkDevice device,
    const VkQueryPoolCreateInfo* pCreateInfo,
    const VkAllocationCallbacks* pAllocator,
    VkQueryPool* pQueryPool);
```

• **device** is the logical device that creates the query pool.
• **pCreateInfo** is a pointer to a VkQueryPoolCreateInfo structure containing the number and type of queries to be managed by the pool.
• **pAllocator** controls host memory allocation as described in the Memory Allocation chapter.
• **pQueryPool** is a pointer to a VkQueryPool handle in which the resulting query pool object is returned.

Valid Usage (Implicit)

• **device** must be a valid VkDevice handle
• **pCreateInfo** must be a valid pointer to a valid VkQueryPoolCreateInfo structure
• If pAllocator is not NULL, **pAllocator** must be a valid pointer to a valid VkAllocationCallbacks structure
• **pQueryPool** must be a valid pointer to a VkQueryPool handle
Return Codes

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY

The `VkQueryPoolCreateInfo` structure is defined as:

```c
typedef struct VkQueryPoolCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkQueryPoolCreateFlags flags;
    VkQueryType queryType;
    uint32_t queryCount;
    VkQueryPipelineStatisticFlags pipelineStatistics;
} VkQueryPoolCreateInfo;
```

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `flags` is reserved for future use.
- `queryType` is a `VkQueryType` value specifying the type of queries managed by the pool.
- `queryCount` is the number of queries managed by the pool.
- `pipelineStatistics` is a bitmask of `VkQueryPipelineStatisticFlagBits` specifying which counters will be returned in queries on the new pool, as described below in Pipeline Statistics Queries.

`pipelineStatistics` is ignored if `queryType` is not `VK_QUERY_TYPE_PIPELINE_STATISTICS`.

Valid Usage

- If the pipeline statistics queries feature is not enabled, `queryType` must not be `VK_QUERY_TYPE_PIPELINE_STATISTICS`.
- If `queryType` is `VK_QUERY_TYPE_PIPELINE_STATISTICS`, `pipelineStatistics` must be a valid combination of `VkQueryPipelineStatisticFlagBits` values.
- If `queryType` is `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, the `pNext` chain must include a structure of type `VkQueryPoolPerformanceCreateInfoKHR`.
- `queryCount` must be greater than 0.
Valid Usage (Implicit)

- **sType** **must** be **VK_STRUCTURE_TYPE_QUERY_POOL_CREATE_INFO**
- Each **pNext** member of any structure (including this one) in the **pNext** chain **must** be either **NULL** or a pointer to a valid instance of **VkQueryPoolPerformanceCreateInfoKHR** or **VkQueryPoolPerformanceQueryCreateInfoINTEL**
- The **sType** value of each struct in the **pNext** chain **must** be unique
- **flags** **must** be **0**
- **queryType** **must** be a valid **VkQueryType** value

```c
typedef VkFlags VkQueryPoolCreateFlags;
```

**VkQueryPoolCreateFlags** is a bitmask type for setting a mask, but is currently reserved for future use.

The **VkQueryPoolPerformanceCreateInfoKHR** structure is defined as:

```c
typedef struct VkQueryPoolPerformanceCreateInfoKHR {
    VkStructureType sType;
    const void* pNext;
    uint32_t queueFamilyIndex;
    uint32_t counterIndexCount;
    const uint32_t* pCounterIndices;
} VkQueryPoolPerformanceCreateInfoKHR;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **queueFamilyIndex** is the queue family index to create this performance query pool for.
- **counterIndexCount** is size of the **pCounterIndices** array.
- **pCounterIndices** is the array of indices into the **vkEnumeratePhysicalDeviceQueueFamilyPerformanceQueryCountersKHR::pCounters** to enable in this performance query pool.

Valid Usage

- **queueFamilyIndex** **must** be a valid queue family index of the device
- The **performanceCounterQueryPools** feature **must** be enabled
- Each element of **pCounterIndices** **must** be in the range of counters reported by **vkEnumeratePhysicalDeviceQueueFamilyPerformanceQueryCountersKHR** for the queue family specified in **queueFamilyIndex**
Valid Usage (Implicit)

- **sType** must be `VK_STRUCTURE_TYPE_QUERY_POOL_PERFORMANCE_CREATE_INFO_KHR`
- **pCounterIndices** must be a valid pointer to an array of `counterIndexCount uint32_t` values
- **counterIndexCount** must be greater than 0

To query the number of passes required to query a performance query pool on a physical device, call:

```c
void vkGetPhysicalDeviceQueueFamilyPerformanceQueryPassesKHR(
    VkPhysicalDevice physicalDevice,
    const VkQueryPoolPerformanceCreateInfoKHR* pPerformanceQueryCreateInfo,
    uint32_t* pNumPasses);
```

- **physicalDevice** is the handle to the physical device whose queue family performance query counter properties will be queried.
- **pPerformanceQueryCreateInfo** is a pointer to a `VkQueryPoolPerformanceCreateInfoKHR` of the performance query that is to be created.
- **pNumPasses** is a pointer to an integer related to the number of passes required to query the performance query pool, as described below.

The **pPerformanceQueryCreateInfo** member `VkQueryPoolPerformanceCreateInfoKHR::queueFamilyIndex` must be a queue family of `physicalDevice`. The number of passes required to capture the counters specified in the **pPerformanceQueryCreateInfo** member `VkQueryPoolPerformanceCreateInfoKHR::pCounters` is returned in `pNumPasses`.

Valid Usage (Implicit)

- **physicalDevice** must be a valid `VkPhysicalDevice` handle
- **pPerformanceQueryCreateInfo** must be a valid pointer to a valid `VkQueryPoolPerformanceCreateInfoKHR` structure
- **pNumPasses** must be a valid pointer to a `uint32_t` value

To destroy a query pool, call:

```c
void vkDestroyQueryPool(
    VkDevice device,            
    VkQueryPool queryPool,     
    const VkAllocationCallbacks* pAllocator);
```

- **device** is the logical device that destroys the query pool.
- **queryPool** is the query pool to destroy.
• `pAllocator` controls host memory allocation as described in the Memory Allocation chapter.

**Valid Usage**

- All submitted commands that refer to `queryPool` must have completed execution
- If `VkAllocationCallbacks` were provided when `queryPool` was created, a compatible set of callbacks must be provided here
- If no `VkAllocationCallbacks` were provided when `queryPool` was created, `pAllocator` must be `NULL`

**Valid Usage (Implicit)**

- `device` must be a valid `VkDevice` handle
- If `queryPool` is not `VK_NULL_HANDLE`, `queryPool` must be a valid `VkQueryPool` handle
- If `pAllocator` is not `NULL`, `pAllocator` must be a valid pointer to a valid `VkAllocationCallbacks` structure
- If `queryPool` is a valid handle, it must have been created, allocated, or retrieved from `device`

**Host Synchronization**

- Host access to `queryPool` must be externally synchronized

Possible values of `VkQueryPoolCreateInfo::queryType`, specifying the type of queries managed by the pool, are:

```c
typedef enum VkQueryType {
    VK_QUERY_TYPE_OCCLUSION = 0,
    VK_QUERY_TYPE_PIPELINE_STATISTICS = 1,
    VK_QUERY_TYPE_TIMESTAMP = 2,
    VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT = 1000028004,
    VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR = 1000116000,
    VK_QUERY_TYPE_ACCELERATION_STRUCTURE_COMPACTED_SIZE_KHR = 1000165000,
    VK_QUERY_TYPE_ACCELERATION_STRUCTURE_SERIALIZATION_SIZE_KHR = 1000150000,
    VK_QUERY_TYPE_PERFORMANCE_QUERY_INTEL = 1000210000,
    VK_QUERY_TYPE_ACCELERATION_STRUCTURE_COMPACTED_SIZE_NV = VK_QUERY_TYPE_ACCELERATION_STRUCTURE_COMPACTED_SIZE_KHR,
} VkQueryType;
```

- `VK_QUERY_TYPE_OCCLUSION` specifies an occlusion query.
- `VK_QUERY_TYPE_PIPELINE_STATISTICS` specifies a pipeline statistics query.
- `VK_QUERY_TYPE_TIMESTAMP` specifies a timestamp query.
• VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR specifies a performance query.
• VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT specifies a transform feedback query.
• VK_QUERY_TYPE_ACCELERATION_STRUCTURE_COMPACTED_SIZE_KHR specifies a ray tracing acceleration structure size query.
• VK_QUERY_TYPE_ACCELERATION_STRUCTURE_SERIALIZATION_SIZE_KHR specifies a ray tracing serialization acceleration structure size query.
• VK_QUERY_TYPE_PERFORMANCE_QUERY_INTEL specifies an Intel performance query.

17.2. Query Operation

The operation of queries is controlled by the commands vkCmdBeginQuery, vkCmdEndQuery, vkCmdBeginQueryIndexedEXT, vkCmdEndQueryIndexedEXT, vkCmdResetQueryPool, vkCmdCopyQueryPoolResults, and vkCmdWriteTimestamp.

In order for a VkCommandBuffer to record query management commands, the queue family for which its VkCommandPool was created must support the appropriate type of operations (graphics, compute) suitable for the query type of a given query pool.

Each query in a query pool has a status that is either unavailable or available, and also has state to store the numerical results of a query operation of the type requested when the query pool was created. Resetting a query via vkCmdResetQueryPool or vkResetQueryPool sets the status to unavailable and makes the numerical results undefined. Performing a query operation with vkCmdBeginQuery and vkCmdEndQuery changes the status to available when the query finishes, and updates the numerical results. Both the availability status and numerical results are retrieved by calling either vkGetQueryPoolResults or vkCmdCopyQueryPoolResults.

Query commands, for the same query and submitted to the same queue, execute in their entirety in submission order, relative to each other. In effect there is an implicit execution dependency from each such query command to all query command previously submitted to the same queue. There is one significant exception to this; if the flags parameter of vkCmdCopyQueryPoolResults does not include VK_QUERY_RESULT_WAIT_BIT, execution of vkCmdCopyQueryPoolResults may happen-before the results of vkCmdEndQuery are available.

After query pool creation, each query must be reset before it is used. Queries must also be reset between uses.

If a logical device includes multiple physical devices, then each command that writes a query must execute on a single physical device, and any call to vkCmdBeginQuery must execute the corresponding vkCmdEndQuery command on the same physical device.

To reset a range of queries in a query pool on a queue, call:
void vkCmdResetQueryPool(
    VkCommandBuffer    commandBuffer,
    VkQueryPool       queryPool,
    uint32_t           firstQuery,
    uint32_t           queryCount);

• `commandBuffer` is the command buffer into which this command will be recorded.
• `queryPool` is the handle of the query pool managing the queries being reset.
• `firstQuery` is the initial query index to reset.
• `queryCount` is the number of queries to reset.

When executed on a queue, this command sets the status of query indices `[firstQuery, firstQuery + queryCount - 1]` to unavailable.

If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, this command sets the status of query indices `[firstQuery, firstQuery + queryCount - 1]` to unavailable for each pass of `queryPool`, as indicated by a call to `vkGetPhysicalDeviceQueueFamilyPerformanceQueryPassesKHR`.

**Note**

Because `vkCmdResetQueryPool` resets all the passes of the indicated queries, applications must not record a `vkCmdResetQueryPool` command for a `queryPool` created with `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR` in a command buffer that needs to be submitted multiple times as indicated by a call to `vkGetPhysicalDeviceQueueFamilyPerformanceQueryPassesKHR`. Otherwise applications will never be able to complete the recorded queries.

**Valid Usage**

• `firstQuery` **must** be less than the number of queries in `queryPool`
• The sum of `firstQuery` and `queryCount` **must** be less than or equal to the number of queries in `queryPool`
• All queries used by the command **must** not be active
• If `queryPool` was created with `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, this command **must** not be recorded in a command buffer that, either directly or through secondary command buffers, also contains begin commands for a query from the set of queries `[firstQuery, firstQuery + queryCount - 1]`
Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `queryPool` **must** be a valid `VkQueryPool` handle
- `commandBuffer` **must** be in the *recording state*
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics, or compute operations
- This command **must** only be called outside of a render pass instance
- Both of `commandBuffer`, and `queryPool` **must** have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>

To reset a range of queries in a query pool on the host, call:

```c
void vkResetQueryPoolEXT(
    VkDevice device,
    VkQueryPool queryPool,
    uint32_t firstQuery,
    uint32_t queryCount);
```

- `device` is the logical device that owns the query pool.
- `queryPool` is the handle of the query pool managing the queries being reset.
- `firstQuery` is the initial query index to reset.
- `queryCount` is the number of queries to reset.

This command sets the status of query indices `[firstQuery, firstQuery + queryCount - 1]` to unavailable.
If `queryPool` is `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR` this command sets the status of query indices `[firstQuery, firstQuery + queryCount - 1]` to unavailable for each pass.

**Valid Usage**

- The `hostQueryReset` feature **must** be enabled
- `firstQuery` **must** be less than the number of queries in `queryPool`
- The sum of `firstQuery` and `queryCount` **must** be less than or equal to the number of queries in `queryPool`
- Submitted commands that refer to the range specified by `firstQuery` and `queryCount` in `queryPool` **must** have completed execution
- The range of queries specified by `firstQuery` and `queryCount` in `queryPool` **must** not be in use by calls to `vkGetQueryPoolResults` or `vkResetQueryPool` in other threads

**Valid Usage (Implicit)**

- `device` **must** be a valid `VkDevice` handle
- `queryPool` **must** be a valid `VkQueryPool` handle
- `queryPool` **must** have been created, allocated, or retrieved from `device`

Once queries are reset and ready for use, query commands **can** be issued to a command buffer. Occlusion queries and pipeline statistics queries count events - drawn samples and pipeline stage invocations, respectively - resulting from commands that are recorded between a `vkCmdBeginQuery` command and a `vkCmdEndQuery` command within a specified command buffer, effectively scoping a set of drawing and/or dispatch commands. Timestamp queries write timestamps to a query pool. Performance queries record performance counters to a query pool.

A query **must** begin and end in the same command buffer, although if it is a primary command buffer, and the inherited queries feature is enabled, it **can** execute secondary command buffers during the query operation. For a secondary command buffer to be executed while a query is active, it **must** set the occlusionQueryEnable, queryFlags, and/or pipelineStatistics members of `VkCommandBufferInheritanceInfo` to conservative values, as described in the Command Buffer Recording section. A query **must** either begin and end inside the same subpass of a render pass instance, or **must** both begin and end outside of a render pass instance (i.e. contain entire render pass instances).

If queries are used while executing a render pass instance that has multiview enabled, the query uses N consecutive query indices in the query pool (starting at `query`) where N is the number of bits set in the view mask in the subpass the query is used in. How the numerical results of the query are distributed among the queries is implementation-dependent. For example, some implementations **may** write each view's results to a distinct query, while other implementations **may** write the total result to the first query and write zero to the other queries. However, the sum of the results in all the queries **must** accurately reflect the total result of the query summed over all views. Applications **can** sum the results from all the queries to compute the total result.
Queries used with multiview rendering **must** not span subpasses, i.e. they **must** begin and end in the same subpass.

To begin a query, call:

```c
void vkCmdBeginQuery(
    VkCommandBuffer commandBuffer,
    VkQueryPool queryPool,
    uint32_t query,
    VkQueryControlFlags flags);
```

- `commandBuffer` is the command buffer into which this command will be recorded.
- `queryPool` is the query pool that will manage the results of the query.
- `query` is the query index within the query pool that will contain the results.
- `flags` is a bitmask of `VkQueryControlFlagBits` specifying constraints on the types of queries that can be performed.

If the `queryType` of the pool is `VK_QUERY_TYPE_OCCLUSION` and `flags` contains `VK_QUERY_CONTROL_PRECISE_BIT`, an implementation **must** return a result that matches the actual number of samples passed. This is described in more detail in Occlusion Queries.

Calling `vkCmdBeginQuery` is equivalent to calling `vkCmdBeginQueryIndexedEXT` with the `index` parameter set to zero.

After beginning a query, that query is considered active within the command buffer it was called in until that same query is ended. Queries active in a primary command buffer when secondary command buffers are executed are considered active for those secondary command buffers.
Valid Usage

- **queryPool** **must** have been created with a **queryType** that differs from that of any queries that are **active** within **commandBuffer**

- All queries used by the command **must** be unavailable

- The **queryType** used to create **queryPool** **must** not be **VK_QUERY_TYPE_TIMESTAMP**

- If the **precise occlusion queries** feature is not enabled, or the **queryType** used to create **queryPool** was not **VK_QUERY_TYPE_OCCLUSION**, **flags** **must** not contain **VK_QUERY_CONTROL_PRECISE_BIT**

- **query** **must** be less than the number of queries in **queryPool**

- If the **queryType** used to create **queryPool** was **VK_QUERY_TYPE_OCCLUSION**, the **VkCommandPool** that **commandBuffer** was allocated from **must** support graphics operations

- If the **queryType** used to create **queryPool** was **VK_QUERY_TYPE_PIPELINE_STATISTICS** and any of the **pipelineStatistics** indicate graphics operations, the **VkCommandPool** that **commandBuffer** was allocated from **must** support graphics operations

- If the **queryType** used to create **queryPool** was **VK_QUERY_TYPE_PIPELINE_STATISTICS** and any of the **pipelineStatistics** indicate compute operations, the **VkCommandPool** that **commandBuffer** was allocated from **must** support compute operations

- If called within a render pass instance, the sum of **query** and the number of bits set in the current subpass’s view mask **must** be less than or equal to the number of queries in **queryPool**

- If the **queryType** used to create **queryPool** was **VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT** the **VkCommandPool** that **commandBuffer** was allocated from **must** support graphics operations

- If the **queryType** used to create **queryPool** was **VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT** then **VkPhysicalDeviceTransformFeedbackPropertiesEXT::transformFeedbackQueries** **must** be supported

- If **queryPool** was created with a **queryType** of **VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR**, the **profiling lock** **must** have been held before **vkBeginCommandBuffer** was called on **commandBuffer**

- If **queryPool** was created with a **queryType** of **VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR** and one of the counters used to create **queryPool** was **VK_PERFORMANCE_COUNTER_SCOPE_COMMAND_BUFFER_KHR**, the query **begin** **must** be the first recorded command in **commandBuffer**

- If **queryPool** was created with a **queryType** of **VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR** and one of the counters used to create **queryPool** was **VK_PERFORMANCE_COUNTER_SCOPE_RENDER_PASS_KHR**, the **begin command** **must** not be recorded within a render pass instance

- If **queryPool** was created with a **queryType** of **VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR** and another query pool with a **queryType** **VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR** has been used within **commandBuffer**, its parent primary command buffer or secondary command buffer recorded within the same parent primary command buffer as **commandBuffer**, the **performanceCounterMultipleQueryPools** feature **must** be enabled
• If `queryPool` was created with a `queryType` of `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, this command **must** not be recorded in a command buffer that, either directly or through secondary command buffers, also contains a `vkCmdResetQueryPool` command affecting the same query.

### Valid Usage (Implicit)

- **commandBuffer** **must** be a valid `VkCommandBuffer` handle.
- **queryPool** **must** be a valid `VkQueryPool` handle.
- **flags** **must** be a valid combination of `VkQueryControlFlagBits` values.
- **commandBuffer** **must** be in the recording state.
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics, or compute operations.
- Both of `commandBuffer`, and `queryPool` **must** have been created, allocated, or retrieved from the same `VkDevice`.

### Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized.
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized.

### Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>

To begin an indexed query, call:

```c
void vkCmdBeginQueryIndexedEXT(
    VkCommandBuffer commandBuffer,
    VkQueryPool queryPool,
    uint32_t query,
    VkQueryControlFlags flags,
    uint32_t index);
```

- **commandBuffer** is the command buffer into which this command will be recorded.
- **queryPool** is the query pool that will manage the results of the query.
• **query** is the query index within the query pool that will contain the results.

• **flags** is a bitmask of `VkQueryControlFlagBits` specifying constraints on the types of queries that can be performed.

• **index** is the query type specific index. When the query type is `VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT` the index represents the vertex stream.

The `vkCmdBeginQueryIndexedEXT` command operates the same as the `vkCmdBeginQuery` command, except that it also accepts a query type specific **index** parameter.
Valid Usage

- `queryPool` must have been created with a `queryType` that differs from that of any queries that are active within `commandBuffer`

- All queries used by the command must be unavailable

- The `queryType` used to create `queryPool` must not be `VK_QUERY_TYPE_TIMESTAMP`

- If the precise occlusion queries feature is not enabled, or the `queryType` used to create `queryPool` was not `VK_QUERY_TYPE_OCCLUSION`, flags must not contain `VK_QUERY_CONTROL_PRECISE_BIT`

- `query` must be less than the number of queries in `queryPool`

- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_OCCLUSION`, the `VkCommandPool` that `commandBuffer` was allocated from must support graphics operations

- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PIPELINE_STATISTICS` and any of the `pipelineStatistics` indicate graphics operations, the `VkCommandPool` that `commandBuffer` was allocated from must support graphics operations

- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PIPELINE_STATISTICS` and any of the `pipelineStatistics` indicate compute operations, the `VkCommandPool` that `commandBuffer` was allocated from must support compute operations

- If called within a render pass instance, the sum of `query` and the number of bits set in the current subpass’s view mask must be less than or equal to the number of queries in `queryPool`

- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT` the `VkCommandPool` that `commandBuffer` was allocated from must support graphics operations

- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT` the index parameter must be less than `VkPhysicalDeviceTransformFeedbackPropertiesEXT::maxTransformFeedbackStreams`

- If the `queryType` used to create `queryPool` was not `VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT` the index must be zero

- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT` then `VkPhysicalDeviceTransformFeedbackPropertiesEXT::transformFeedbackQueries` must be supported

- If `queryPool` was created with a `queryType` of `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, the profiling lock must have been held before `vkBeginCommandBuffer` was called on `commandBuffer`

- If `queryPool` was created with a `queryType` of `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR` and one of the counters used to create `queryPool` was `VK_PERFORMANCE_COUNTER_SCOPE_COMMAND_BUFFER_KHR`, the query begin must be the first recorded command in `commandBuffer`

- If `queryPool` was created with a `queryType` of `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR` and one of the counters used to create `queryPool` was `VK_PERFORMANCE_COUNTER_SCOPE_RENDER_PASS_KHR`, the begin command must not be recorded
within a render pass instance

• If `queryPool` was created with a `queryType` of `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR` and another query pool with a `queryType` `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR` has been used within `commandBuffer`, its parent primary command buffer or secondary command buffer recorded within the same parent primary command buffer as `commandBuffer`, the `performanceCounterMultipleQueryPools` feature must be enabled

• If `queryPool` was created with a `queryType` of `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, this command must not be recorded in a command buffer that, either directly or through secondary command buffers, also contains a `vkCmdResetQueryPool` command affecting the same query

**Valid Usage (Implicit)**

• `commandBuffer` must be a valid `VkCommandBuffer` handle

• `queryPool` must be a valid `VkQueryPool` handle

• `flags` must be a valid combination of `VkQueryControlFlagBits` values

• `commandBuffer` must be in the recording state

• The `VkCommandPool` that `commandBuffer` was allocated from must support graphics, or compute operations

• Both of `commandBuffer`, and `queryPool` must have been created, allocated, or retrieved from the same `VkDevice`

**Host Synchronization**

• Host access to `commandBuffer` must be externally synchronized

• Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

**Command Properties**

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary, Secondary</td>
<td>Both</td>
<td>Graphics, Compute</td>
<td></td>
</tr>
</tbody>
</table>

Bits which can be set in `vkCmdBeginQuery::flags`, specifying constraints on the types of queries that can be performed, are:
typedef enum VkQueryControlFlagBits {
    VK_QUERY_CONTROL_PRECISE_BIT = 0x00000001,
} VkQueryControlFlagBits;

- VK_QUERY_CONTROL_PRECISE_BIT specifies the precision of occlusion queries.

typedef VkFlags VkQueryControlFlags;

VkQueryControlFlags is a bitmask type for setting a mask of zero or more VkQueryControlFlagBits.

To end a query after the set of desired draw or dispatch commands is executed, call:

```c
void vkCmdEndQuery(
    VkCommandBuffer commandBuffer,
    VkQueryPool queryPool,
    uint32_t query);
```

- `commandBuffer` is the command buffer into which this command will be recorded.
- `queryPool` is the query pool that is managing the results of the query.
- `query` is the query index within the query pool where the result is stored.

Calling `vkCmdEndQuery` is equivalent to calling `vkCmdEndQueryIndexedEXT` with the `index` parameter set to zero.

As queries operate asynchronously, ending a query does not immediately set the query's status to available. A query is considered *finished* when the final results of the query are ready to be retrieved by `vkGetQueryPoolResults` and `vkCmdCopyQueryPoolResults`, and this is when the query's status is set to available.

Once a query is ended the query **must** finish in finite time, unless the state of the query is changed using other commands, e.g. by issuing a reset of the query.
Valid Usage

• All queries used by the command must be active

• query must be less than the number of queries in queryPool

• If vkCmdEndQuery is called within a render pass instance, the sum of query and the number of bits set in the current subpass’s view mask must be less than or equal to the number of queries in queryPool

• If queryPool was created with a queryType of VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR and one or more of the counters used to create queryPool was VK_PERFORMANCE_COUNTER_SCOPE_COMMAND_BUFFER_KHR, the vkCmdEndQuery must be the last recorded command in commandBuffer

• If queryPool was created with a queryType of VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR and one or more of the counters used to create queryPool was VK_PERFORMANCE_COUNTER_SCOPE_RENDER_PASS_KHR, the vkCmdEndQuery must not be recorded within a render pass instance

Valid Usage (Implicit)

• commandBuffer must be a valid VkCommandBuffer handle

• queryPool must be a valid VkQueryPool handle

• commandBuffer must be in the recording state

• The VkCommandPool that commandBuffer was allocated from must support graphics, or compute operations

• Both of commandBuffer, and queryPool must have been created, allocated, or retrieved from the same VkDevice

Host Synchronization

• Host access to commandBuffer must be externally synchronized

• Host access to the VkCommandPool that commandBuffer was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>

</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Both</td>
<td>Graphics</td>
<td></td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td>Compute</td>
<td></td>
</tr>
</tbody>
</table>
To end an indexed query after the set of desired draw or dispatch commands is recorded, call:

```c
void vkCmdEndQueryIndexedEXT(
    VkCommandBuffer                             commandBuffer,
    VkQueryPool                                 queryPool,
    uint32_t                                    query,
    uint32_t                                    index);
```

- `commandBuffer` is the command buffer into which this command will be recorded.
- `queryPool` is the query pool that is managing the results of the query.
- `query` is the query index within the query pool where the result is stored.
- `index` is the query type specific index.

The `vkCmdEndQueryIndexedEXT` command operates the same as the `vkCmdEndQuery` command, except that it also accepts a query type specific `index` parameter.

### Valid Usage

- All queries used by the command **must** be active
- `query` **must** be less than the number of queries in `queryPool`
- If `vkCmdEndQueryIndexedEXT` is called within a render pass instance, the sum of `query` and the number of bits set in the current subpass’s view mask **must** be less than or equal to the number of queries in `queryPool`
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT` the `index` parameter **must** be less than `VkPhysicalDeviceTransformFeedbackPropertiesEXT::maxTransformFeedbackStreams`
- If the `queryType` used to create `queryPool` was not `VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT` the `index` **must** be zero
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_TRANSFORM_FEEDBACK_STREAM_EXT` `index` **must** equal the `index` used to begin the query

### Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `queryPool` **must** be a valid `VkQueryPool` handle
- `commandBuffer` **must** be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics, or compute operations
- Both of `commandBuffer`, and `queryPool` **must** have been created, allocated, or retrieved from the same `VkDevice`
### Host Synchronization

- Host access to `commandBuffer` must be externally synchronized.
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized.

### Command Properties

<table>
<thead>

</table>

An application can retrieve results either by requesting they be written into application-provided memory, or by requesting they be copied into a `VkBuffer`. In either case, the layout in memory is defined as follows:

- The first query's result is written starting at the first byte requested by the command, and each subsequent query's result begins `stride` bytes later.

- Occlusion queries, pipeline statistics queries, transform feedback queries, and timestamp queries store results in a tightly packed array of unsigned integers, either 32- or 64-bits as requested by the command, storing the numerical results and, if requested, the availability status.

- Performance queries store results in a tightly packed array whose type is determined by the `unit` member of the corresponding `VkPerformanceCounterKHR`.

- If `VK_QUERY_RESULT_WITH_AVAILABILITY_BIT` is used, the final element of each query's result is an integer indicating whether the query's result is available, with any non-zero value indicating that it is available.

- Occlusion queries write one integer value - the number of samples passed. Pipeline statistics queries write one integer value for each bit that is enabled in the `pipelineStatistics` when the pool is created, and the statistics values are written in bit order starting from the least significant bit. Timestamp queries write one integer value. Performance queries write one `VkPerformanceCounterResultKHR` value for each `VkPerformanceCounterKHR` in the query. Transform feedback queries write two integers; the first integer is the number of primitives successfully written to the corresponding transform feedback buffer and the second is the number of primitives output to the vertex stream, regardless of whether they were successfully captured or not. In other words, if the transform feedback buffer was sized too small for the number of primitives output by the vertex stream, the first integer represents the number of primitives actually written and the second is the number that would have been written if all the transform feedback buffers associated with that vertex stream were large enough.

- If more than one query is retrieved and `stride` is not at least as large as the size of the array of values corresponding to a single query, the values written to memory are undefined.
To retrieve status and results for a set of queries, call:

```c
VkResult vkGetQueryPoolResults(
    VkDevice device,  
    VkQueryPool queryPool, 
    uint32_t firstQuery, 
    uint32_t queryCount, 
    size_t dataSize,  
    void* pData, 
    VkDeviceSize stride, 
    VkQueryResultFlags flags);
```

- **device** is the logical device that owns the query pool.
- **queryPool** is the query pool managing the queries containing the desired results.
- **firstQuery** is the initial query index.
- **queryCount** is the number of queries to read.
- **dataSize** is the size in bytes of the buffer pointed to by `pData`.
- **pData** is a pointer to a user-allocated buffer where the results will be written.
- **stride** is the stride in bytes between results for individual queries within `pData`.
- **flags** is a bitmask of `VkQueryResultFlagBits` specifying how and when results are returned.

The range of queries read is defined by `[firstQuery, firstQuery + queryCount - 1]`. For pipeline statistics queries, each query index in the pool contains one integer value for each bit that is enabled in `VkQueryPoolCreateInfo::pipelineStatistics` when the pool is created.

If no bits are set in `flags`, and all requested queries are in the available state, results are written as an array of 32-bit unsigned integer values. The behavior when not all queries are available, is described below.

If `VK_QUERY_RESULT_64_BIT` is not set and the result overflows a 32-bit value, the value may either wrap or saturate. Similarly, if `VK_QUERY_RESULT_64_BIT` is set and the result overflows a 64-bit value, the value may either wrap or saturate.

If `VK_QUERY_RESULT_WAIT_BIT` is set, Vulkan will wait for each query to be in the available state before retrieving the numerical results for that query. In this case, `vkGetQueryPoolResults` is guaranteed to succeed and return `VK_SUCCESS` if the queries become available in a finite time (i.e. if they have been issued and not reset). If queries will never finish (e.g. due to being reset but not issued), then `vkGetQueryPoolResults` may not return in finite time.

If `VK_QUERY_RESULT_WAIT_BIT` and `VK_QUERY_RESULT_PARTIAL_BIT` are both not set then no result values are written to `pData` for queries that are in the unavailable state at the time of the call, and `vkGetQueryPoolResults` returns `VK_NOT_READY`. However, availability state is still written to `pData` for those queries if `VK_QUERY_RESULT_WITH_AVAILABILITY_BIT` is set.
Applications **must** take care to ensure that use of the `VK_QUERY_RESULT_WAIT_BIT` bit has the desired effect.

For example, if a query has been used previously and a command buffer records the commands `vkCmdResetQueryPool`, `vkCmdBeginQuery`, and `vkCmdEndQuery` for that query, then the query will remain in the available state until `vkResetQueryPool` is called or the `vkCmdResetQueryPool` command executes on a queue. Applications **can** use fences or events to ensure that a query has already been reset before checking for its results or availability status. Otherwise, a stale value could be returned from a previous use of the query.

The above also applies when `VK_QUERY_RESULT_WAIT_BIT` is used in combination with `VK_QUERY_RESULT_WITH_AVAILABILITY_BIT`. In this case, the returned availability status **may** reflect the result of a previous use of the query unless `vkResetQueryPool` is called or the `vkCmdResetQueryPool` command has been executed since the last use of the query.

Applications **can** double-buffer query pool usage, with a pool per frame, and reset queries at the end of the frame in which they are read.

If `VK_QUERY_RESULT_PARTIAL_BIT` is set, `VK_QUERY_RESULT_WAIT_BIT` is not set, and the query's status is unavailable, an intermediate result value between zero and the final result value is written to `pData` for that query.

If `VK_QUERY_RESULT_WITH_AVAILABILITY_BIT` is set, the final integer value written for each query is non-zero if the query's status was available or zero if the status was unavailable. When `VK_QUERY_RESULT_WITH_AVAILABILITY_BIT` is used, implementations **must** guarantee that if they return a non-zero availability value then the numerical results **must** be valid, assuming the results are not reset by a subsequent command.

Satisfying this guarantee **may** require careful ordering by the application, e.g. to read the availability status before reading the results.
Valid Usage

- **firstQuery** must be less than the number of queries in `queryPool`
- If `VK_QUERY_RESULT_64_BIT` is not set in `flags`, then `pData` and `stride` must be multiples of 4
- If `VK_QUERY_RESULT_64_BIT` is not set in `flags` and the `queryType` used to create `queryPool` was not `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, then `pData` and `stride` must be multiples of 4
- If `VK_QUERY_RESULT_64_BIT` is set in `flags` then `pData` and `stride` must be multiples of 8
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, then `pData` and `stride` must be multiples of the size of `VkPerformanceCounterResultKHR`
- The sum of `firstQuery` and `queryCount` must be less than or equal to the number of queries in `queryPool`
- `dataSize` must be large enough to contain the result of each query, as described here
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_TIMESTAMP`, `flags` must not contain `VK_QUERY_RESULT_PARTIAL_BIT`
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, `flags` must not contain `VK_QUERY_RESULT_WITH_AVAILABILITY_BIT`, `VK_QUERY_RESULT_PARTIAL_BIT` or `VK_QUERY_RESULT_64_BIT`
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, the `queryPool` must have been recorded once for each pass as retrieved via a call to `vkGetPhysicalDeviceQueueFamilyPerformanceQueryPassesKHR`

Valid Usage (Implicit)

- `device` must be a valid `VkDevice` handle
- `queryPool` must be a valid `VkQueryPool` handle
- `pData` must be a valid pointer to an array of `dataSize` bytes
- `flags` must be a valid combination of `VkQueryResultFlagBits` values
- `dataSize` must be greater than 0
- `queryPool` must have been created, allocated, or retrieved from `device`
Return Codes

Success

- VK_SUCCESS
- VK_NOT_READY

Failure

- VK_ERROR_OUT_OF_HOST_MEMORY
- VK_ERROR_OUT_OF_DEVICE_MEMORY
- VK_ERROR_DEVICE_LOST

Bits which can be set in `vkGetQueryPoolResults::flags` and `vkCmdCopyQueryPoolResults::flags`, specifying how and when results are returned, are:

```c
typedef enum VkQueryResultFlagBits {
    VK_QUERY_RESULT_64_BIT = 0x00000001,
    VK_QUERY_RESULT_WAIT_BIT = 0x00000002,
    VK_QUERY_RESULT_WITH_AVAILABILITY_BIT = 0x00000004,
    VK_QUERY_RESULT_PARTIAL_BIT = 0x00000008,
} VkQueryResultFlagBits;
```

- **VK_QUERY_RESULT_64_BIT** specifies the results will be written as an array of 64-bit unsigned integer values. If this bit is not set, the results will be written as an array of 32-bit unsigned integer values.

- **VK_QUERY_RESULT_WAIT_BIT** specifies that Vulkan will wait for each query's status to become available before retrieving its results.

- **VK_QUERY_RESULT_WITH_AVAILABILITY_BIT** specifies that the availability status accompanies the results.

- **VK_QUERY_RESULT_PARTIAL_BIT** specifies that returning partial results is acceptable.

```c
typedef VkFlags VkQueryResultFlags;
```

**VkQueryResultFlags** is a bitmask type for setting a mask of zero or more **VkQueryResultFlagBits**.

To copy query statuses and numerical results directly to buffer memory, call:
void vkCmdCopyQueryPoolResults(
    VkCommandBuffer                             commandBuffer,
    VkQueryPool                                 queryPool,
    uint32_t                                    firstQuery,
    uint32_t                                    queryCount,
    VkBuffer                                    dstBuffer,
    VkDeviceSize                                dstOffset,
    VkDeviceSize                                stride,
    VkQueryResultFlags                          flags);

- commandBuffer is the command buffer into which this command will be recorded.
- queryPool is the query pool managing the queries containing the desired results.
- firstQuery is the initial query index.
- queryCount is the number of queries. firstQuery and queryCount together define a range of queries.
- dstBuffer is a VkBuffer object that will receive the results of the copy command.
- dstOffset is an offset into dstBuffer.
- stride is the stride in bytes between results for individual queries within dstBuffer. The required size of the backing memory for dstBuffer is determined as described above for vkGetQueryPoolResults.
- flags is a bitmask of VkQueryResultFlagBits specifying how and when results are returned.

vkCmdCopyQueryPoolResults is guaranteed to see the effect of previous uses of vkCmdResetQueryPool in the same queue, without any additional synchronization. Thus, the results will always reflect the most recent use of the query.

flags has the same possible values described above for the flags parameter of vkGetQueryPoolResults, but the different style of execution causes some subtle behavioral differences. Because vkCmdCopyQueryPoolResults executes in order with respect to other query commands, there is less ambiguity about which use of a query is being requested.

Results for all requested occlusion queries, pipeline statistics queries, transform feedback queries, and timestamp queries are written as 64-bit unsigned integer values if VK_QUERY_RESULT_64_BIT is set or 32-bit unsigned integer values otherwise. Performance queries store results in a tightly packed array whose type is determined by the unit member of the corresponding VkPerformanceCounterKHR.

If neither of VK_QUERY_RESULT_WAIT_BIT and VK_QUERY_RESULT_WITH_AVAILABILITY_BIT are set, results are only written out for queries in the available state.

If VK_QUERY_RESULT_WAIT_BIT is set, the implementation will wait for each query's status to be in the available state before retrieving the numerical results for that query. This is guaranteed to reflect the most recent use of the query on the same queue, assuming that the query is not being simultaneously used by other queues. If the query does not become available in a finite amount of time (e.g. due to not issuing a query since the last reset), a VK_ERROR_DEVICE_LOST error may occur.
Similarly, if `VK_QUERY_RESULT_WITH_AVAILABILITY_BIT` is set and `VK_QUERY_RESULT_WAIT_BIT` is not set, the availability is guaranteed to reflect the most recent use of the query on the same queue, assuming that the query is not being simultaneously used by other queues. As with `vkGetQueryPoolResults`, implementations must guarantee that if they return a non-zero availability value, then the numerical results are valid.

If `VK_QUERY_RESULT_PARTIAL_BIT` is set, `VK_QUERY_RESULT_WAIT_BIT` is not set, and the query’s status is unavailable, an intermediate result value between zero and the final result value is written for that query.

`VK_QUERY_RESULT_PARTIAL_BIT` must not be used if the pool’s `queryType` is `VK_QUERY_TYPE_TIMESTAMP`.

`vkCmdCopyQueryPoolResults` is considered to be a transfer operation, and its writes to buffer memory must be synchronized using `VK_PIPELINE_STAGE_TRANSFER_BIT` and `VK_ACCESS_TRANSFER_WRITE_BIT` before using the results.

---

### Valid Usage

- **dstOffset** must be less than the size of `dstBuffer`
- **firstQuery** must be less than the number of queries in `queryPool`
- The sum of **firstQuery** and **queryCount** must be less than or equal to the number of queries in `queryPool`
- If `VK_QUERY_RESULT_64_BIT` is not set in `flags` then **dstOffset** and **stride** must be multiples of 4
- If `VK_QUERY_RESULT_64_BIT` is set in `flags` then **dstOffset** and **stride** must be multiples of 8
- **dstBuffer** must have enough storage, from **dstOffset**, to contain the result of each query, as described [here](#)
- **dstBuffer** must have been created with `VK_BUFFER_USAGE_TRANSFER_DST_BIT` usage flag
- If **dstBuffer** is non-sparse then it must be bound completely and contiguously to a single `VkDeviceMemory` object
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_TIMESTAMP`, **flags** must not contain `VK_QUERY_RESULT_PARTIAL_BIT`
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, `VkPhysicalDevicePerformanceQueryPropertiesKHR::allowCommandBufferQueryCopies` must be `VK_TRUE`
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, **flags** must not contain `VK_QUERY_RESULT_WITH_AVAILABILITY_BIT`, `VK_QUERY_RESULT_PARTIAL_BIT` or `VK_QUERY_RESULT_64_BIT`
- If the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PERFORMANCE_QUERY_KHR`, the `queryPool` must have been submitted once for each pass as retrieved via a call to `vkGetPhysicalDeviceQueueFamilyPerformanceQueryPassesKHR`
- `vkCmdCopyQueryPoolResults` must not be called if the `queryType` used to create `queryPool` was `VK_QUERY_TYPE_PERFORMANCE_QUERY_INTEL`
Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `queryPool` **must** be a valid `VkQueryPool` handle
- `dstBuffer` **must** be a valid `VkBuffer` handle
- `flags` **must** be a valid combination of `VkQueryResultFlagBits` values
- `commandBuffer` **must** be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics, or compute operations
- This command **must** only be called outside of a render pass instance
- Each of `commandBuffer`, `dstBuffer`, and `queryPool` **must** have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized

Rendering operations such as clears, MSAA resolves, attachment load/store operations, and blits **may** count towards the results of queries. This behavior is implementation-dependent and **may** vary depending on the path used within an implementation. For example, some implementations have several types of clears, some of which **may** include vertices and some not.

17.3. Occlusion Queries

Occlusion queries track the number of samples that pass the per-fragment tests for a set of drawing commands. As such, occlusion queries are only available on queue families supporting graphics operations. The application **can** then use these results to inform future rendering decisions. An occlusion query is begun and ended by calling `vkCmdBeginQuery` and `vkCmdEndQuery`, respectively. When an occlusion query begins, the count of passing samples always starts at zero. For each drawing command, the count is incremented as described in Sample Counting. If `flags` does not contain `VK_QUERY_CONTROL_PRECISE_BIT` an implementation **may** generate any non-zero result value.
for the query if the count of passing samples is non-zero.

**Note**

Not setting `VK_QUERY_CONTROL_PRECISE_BIT` mode **may** be more efficient on some implementations, and **should** be used where it is sufficient to know a boolean result on whether any samples passed the per-fragment tests. In this case, some implementations **may** only return zero or one, indifferent to the actual number of samples passing the per-fragment tests.

When an occlusion query finishes, the result for that query is marked as available. The application **can** then either copy the result to a buffer (via `vkCmdCopyQueryPoolResults`) or request it be put into host memory (via `vkGetQueryPoolResults`).

**Note**

If occluding geometry is not drawn first, samples **can** pass the depth test, but still not be visible in a final image.

### 17.4. Pipeline Statistics Queries

Pipeline statistics queries allow the application to sample a specified set of `VkPipeline` counters. These counters are accumulated by Vulkan for a set of either draw or dispatch commands while a pipeline statistics query is active. As such, pipeline statistics queries are available on queue families supporting either graphics or compute operations. The availability of pipeline statistics queries is indicated by the `pipelineStatisticsQuery` member of the `VkPhysicalDeviceFeatures` object (see `vkGetPhysicalDeviceFeatures` and `vkCreateDevice` for detecting and requesting this query type on a `VkDevice`).

A pipeline statistics query is begun and ended by calling `vkCmdBeginQuery` and `vkCmdEndQuery`, respectively. When a pipeline statistics query begins, all statistics counters are set to zero. While the query is active, the pipeline type determines which set of statistics are available, but these **must** be configured on the query pool when it is created. If a statistic counter is issued on a command buffer that does not support the corresponding operation, the value of that counter is undefined after the query has finished. At least one statistic counter relevant to the operations supported on the recording command buffer **must** be enabled.

Bits which **can** be set to individually enable pipeline statistics counters for query pools with `VkQueryPoolCreateInfo::pipelineStatistics`, and for secondary command buffers with `VkCommandBufferInheritanceInfo::pipelineStatistics`, are:
typedef enum VkQueryPipelineStatisticFlagBits {
    VK_QUERY_PIPELINE_STATISTIC_INPUT_ASSEMBLY_VERTICES_BIT = 0x00000001,
    VK_QUERY_PIPELINE_STATISTIC_INPUT_ASSEMBLY_PRIMITIVES_BIT = 0x00000002,
    VK_QUERY_PIPELINE_STATISTIC_VERTEX_SHADER_INVOCATIONS_BIT = 0x00000004,
    VK_QUERY_PIPELINE_STATISTIC_GEOMETRY_SHADER_INVOCATIONS_BIT = 0x00000008,
    VK_QUERY_PIPELINE_STATISTIC_GEOMETRY_SHADER_PRIMITIVES_BIT = 0x00000010,
    VK_QUERY_PIPELINE_STATISTIC_CLIPPING_INVOCATIONS_BIT = 0x00000020,
    VK_QUERY_PIPELINE_STATISTIC_CLIPPING_PRIMITIVES_BIT = 0x00000040,
    VK_QUERY_PIPELINE_STATISTIC_FRAGMENT_SHADER_INVOCATIONS_BIT = 0x00000080,
    VK_QUERY_PIPELINE_STATISTIC_TESSELLATION_CONTROL_SHADER_PATCHES_BIT = 0x00000100,
    VK_QUERY_PIPELINE_STATISTIC_TESSELLATION_EVALUATION_SHADER_INVOCATIONS_BIT = 0x00000200,
    VK_QUERY_PIPELINE_STATISTIC_COMPUTE_SHADER_INVOCATIONS_BIT = 0x00000400,
} VkQueryPipelineStatisticFlagBits;

• **VK_QUERY_PIPELINE_STATISTIC_INPUT_ASSEMBLY_VERTICES_BIT** specifies that queries managed by the pool will count the number of vertices processed by the **input assembly** stage. Vertices corresponding to incomplete primitives **may** contribute to the count.

• **VK_QUERY_PIPELINE_STATISTIC_INPUT_ASSEMBLY_PRIMITIVES_BIT** specifies that queries managed by the pool will count the number of primitives processed by the **input assembly** stage. If primitive restart is enabled, restarting the primitive topology has no effect on the count. Incomplete primitives **may** be counted.

• **VK_QUERY_PIPELINE_STATISTIC_VERTEX_SHADER_INVOCATIONS_BIT** specifies that queries managed by the pool will count the number of vertex shader invocations. This counter’s value is incremented each time a vertex shader is **invoked**.

• **VK_QUERY_PIPELINE_STATISTIC_GEOMETRY_SHADER_INVOCATIONS_BIT** specifies that queries managed by the pool will count the number of geometry shader invocations. This counter’s value is incremented each time a geometry shader is **invoked**. In the case of **instanced geometry shaders**, the geometry shader invocations count is incremented for each separate instanced invocation.

• **VK_QUERY_PIPELINE_STATISTIC_GEOMETRY_SHADER_PRIMITIVES_BIT** specifies that queries managed by the pool will count the number of primitives generated by geometry shader invocations. The counter’s value is incremented each time the geometry shader emits a primitive. Restarting primitive topology using the SPIR-V instructions **OpEndPrimitive** or **OpEndStreamPrimitive** has no effect on the geometry shader output primitives count.

• **VK_QUERY_PIPELINE_STATISTIC_CLIPPING_INVOCATIONS_BIT** specifies that queries managed by the pool will count the number of primitives processed by the **Primitive Clipping** stage of the pipeline. The counter’s value is incremented each time a primitive reaches the primitive clipping stage.

• **VK_QUERY_PIPELINE_STATISTIC_CLIPPING_PRIMITIVES_BIT** specifies that queries managed by the pool will count the number of primitives output by the **Primitive Clipping** stage of the pipeline. The actual number of primitives output by the primitive clipping stage for a particular input primitive is implementation-dependent but **must** satisfy the following conditions:
  
  ◦ If at least one vertex of the input primitive lies inside the clipping volume, the counter is
incremented by one or more.

- Otherwise, the counter is incremented by zero or more.

- **VK_QUERY_PIPELINE_STATISTIC_FRAGMENT_SHADER_INVOCATIONS_BIT** specifies that queries managed by the pool will count the number of fragment shader invocations. The counter’s value is incremented each time the fragment shader is *invoked*.

- **VK_QUERY_PIPELINE_STATISTIC_TESSELLATION_CONTROL_SHADER_PATCHES_BIT** specifies that queries managed by the pool will count the number of patches processed by the tessellation control shader. The counter’s value is incremented once for each patch for which a tessellation control shader is *invoked*.

- **VK_QUERY_PIPELINE_STATISTIC_TESSELLATION_EVALUATION_SHADER_INVOCATIONS_BIT** specifies that queries managed by the pool will count the number of invocations of the tessellation evaluation shader. The counter’s value is incremented each time the tessellation evaluation shader is *invoked*.

- **VK_QUERY_PIPELINE_STATISTIC_COMPUTE_SHADER_INVOCATIONS_BIT** specifies that queries managed by the pool will count the number of compute shader invocations. The counter’s value is incremented every time the compute shader is invoked. Implementations may skip the execution of certain compute shader invocations or execute additional compute shader invocations for implementation-dependent reasons as long as the results of rendering otherwise remain unchanged.

These values are intended to measure relative statistics on one implementation. Various device architectures will count these values differently. Any or all counters may be affected by the issues described in Query Operation.

---

**Note**

For example, tile-based rendering devices may need to replay the scene multiple times, affecting some of the counts.

If a pipeline has *rasterizerDiscardEnable* enabled, implementations may discard primitives after the final vertex processing stage. As a result, if *rasterizerDiscardEnable* is enabled, the clipping input and output primitives counters may not be incremented.

When a pipeline statistics query finishes, the result for that query is marked as available. The application can copy the result to a buffer (via `vkCmdCopyQueryPoolResults`), or request it be put into host memory (via `vkGetQueryPoolResults`).

```c
typedef VkFlags VkQueryPipelineStatisticFlags;
```

*VkQueryPipelineStatisticFlags* is a bitmask type for setting a mask of zero or more *VkQueryPipelineStatisticFlagBits*.

### 17.5. Timestamp Queries

Timestamps provide applications with a mechanism for timing the execution of commands. A timestamp is an integer value generated by the *VkPhysicalDevice*. Unlike other queries, timestamps
do not operate over a range, and so do not use `vkCmdBeginQuery` or `vkCmdEndQuery`. The mechanism is built around a set of commands that allow the application to tell the `VkPhysicalDevice` to write timestamp values to a query pool and then either read timestamp values on the host (using `vkGetQueryPoolResults`) or copy timestamp values to a `VkBuffer` (using `vkCmdCopyQueryPoolResults`). The application can then compute differences between timestamps to determine execution time.

The number of valid bits in a timestamp value is determined by the `VkQueueFamilyProperties::timestampValidBits` property of the queue on which the timestamp is written. Timestamps are supported on any queue which reports a non-zero value for `timestampValidBits` via `vkGetPhysicalDeviceQueueFamilyProperties`. If the `timestampComputeAndGraphics` limit is `VK_TRUE`, timestamps are supported by every queue family that supports either graphics or compute operations (see `VkQueueFamilyProperties`).

The number of nanoseconds it takes for a timestamp value to be incremented by 1 can be obtained from `VkPhysicalDeviceLimits::timestampPeriod` after a call to `vkGetPhysicalDeviceProperties`.

To request a timestamp, call:

```c
void vkCmdWriteTimestamp(
    VkCommandBuffer commandBuffer,
    VkPipelineStageFlagBits pipelineStage,
    VkQueryPool queryPool,
    uint32_t query);
```

- `commandBuffer` is the command buffer into which the command will be recorded.
- `pipelineStage` is one of the `VkPipelineStageFlagBits`, specifying a stage of the pipeline.
- `queryPool` is the query pool that will manage the timestamp.
- `query` is the query within the query pool that will contain the timestamp.

`vkCmdWriteTimestamp` latches the value of the timer when all previous commands have completed executing as far as the specified pipeline stage, and writes the timestamp value to memory. When the timestamp value is written, the availability status of the query is set to available.

**Note**

If an implementation is unable to detect completion and latch the timer at any specific stage of the pipeline, it may instead do so at any logically later stage.

`vkCmdCopyQueryPoolResults` can then be called to copy the timestamp value from the query pool into buffer memory, with ordering and synchronization behavior equivalent to how other queries operate. Timestamp values can also be retrieved from the query pool using `vkGetQueryPoolResults`. As with other queries, the query must be reset using `vkCmdResetQueryPool` or `vkResetQueryPool` before requesting the timestamp value be written to it.

While `vkCmdWriteTimestamp` can be called inside or outside of a render pass instance, `vkCmdCopyQueryPoolResults` must only be called outside of a render pass instance.
Timestamps **may** only be meaningfully compared if they are written by commands submitted to the same queue.

**Note**
An example of such a comparison is determining the execution time of a sequence of commands.

If `vkCmdWriteTimestamp` is called while executing a render pass instance that has multiview enabled, the timestamp uses N consecutive query indices in the query pool (starting at `query`) where N is the number of bits set in the view mask of the subpass the command is executed in. The resulting query values are determined by an implementation-dependent choice of one of the following behaviors:

- The first query is a timestamp value and (if more than one bit is set in the view mask) zero is written to the remaining queries. If two timestamps are written in the same subpass, the sum of the execution time of all views between those commands is the difference between the first query written by each command.

- All N queries are timestamp values. If two timestamps are written in the same subpass, the sum of the execution time of all views between those commands is the sum of the difference between corresponding queries written by each command. The difference between corresponding queries **may** be the execution time of a single view.

In either case, the application **can** sum the differences between all N queries to determine the total execution time.

---

**Valid Usage**

- `queryPool` **must** have been created with a `queryType` of `VK_QUERY_TYPE_TIMESTAMP`
- The query identified by `queryPool` and `query` **must** be unavailable
- The command pool's queue family **must** support a non-zero `timestampValidBits`
- All queries used by the command **must** be unavailable
- If `vkCmdWriteTimestamp` is called within a render pass instance, the sum of `query` and the number of bits set in the current subpass's view mask **must** be less than or equal to the number of queries in `queryPool`
**Valid Usage (Implicit)**

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `pipelineStage` must be a valid `VkPipelineStageFlagBits` value
- `queryPool` must be a valid `VkQueryPool` handle
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support transfer, graphics, or compute operations
- Both of `commandBuffer` and `queryPool` must have been created, allocated, or retrieved from the same `VkDevice`

**Host Synchronization**

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

**Command Properties**

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>

</tbody>
</table>

**17.6. Performance Queries**

*Performance queries* provide applications with a mechanism for getting performance counter information about the execution of command buffers, render passes, and commands.

Each queue family advertises the performance counters that *can* be queried on a queue of that family via a call to `vkEnumeratePhysicalDeviceQueueFamilyPerformanceQueryCountersKHR`. Implementations *may* limit access to performance counters based on platform requirements or only to specialized drivers for development purposes.

**Note**

This may include no performance counters being enumerated, or a reduced set. Please refer to platform-specific documentation for guidance on any such restrictions.

Performance queries use the existing `vkCmdBeginQuery` and `vkCmdEndQuery` to control what...
command buffers, render passes, or commands to get performance information for.

Implementations may require multiple passes where the command buffer, render passes, or commands being recorded are the same and are executed on the same queue to record performance counter data. This is achieved by submitting the same batch and providing a VkPerformanceQuerySubmitInfoKHR structure containing a counter pass index. The number of passes required for a given performance query pool can be queried via a call to vkGetPhysicalDeviceQueueFamilyPerformanceQueryPassesKHR.

Note
Command buffers created with VK_COMMAND_BUFFER_USAGE_ONE_TIME_SUBMIT_BIT must not be re-submitted. Changing command buffer usage bits may affect performance. To avoid this, the application should re-record any command buffers with the VK_COMMAND_BUFFER_USAGE_ONE_TIME_SUBMIT_BIT when multiple counter passes are required.

Performance counter results from a performance query pool can be obtained with the command vkGetQueryPoolResults.

Performance query results are returned in an array of VkPerformanceCounterResultKHR unions containing the data associated with each counter in the query, stored in the same order as the counters supplied in pCounterIndices when creating the performance query. The VkPerformanceCounterKHR::unit enumeration specifies how to parse the counter data.

```c
typedef union VkPerformanceCounterResultKHR {
    int32_t     int32;
    int64_t     int64;
    uint32_t    uint32;
    uint64_t    uint64;
    float       float32;
    double      float64;
} VkPerformanceCounterResultKHR;
```

### 17.6.1. Profiling Lock

To record and submit a command buffer that contains a performance query pool the profiling lock must be held. The profiling lock must be acquired prior to any call to vkBeginCommandBuffer that will be using a performance query pool. The profiling lock must be held while any command buffer that contains a performance query pool is in the recording, executable, or pending state. To acquire the profiling lock, call:

```c
VkResult vkAcquireProfilingLockKHR(VkDevice device, const VkAcquireProfilingLockInfoKHR* pInfo);
```

- device is the logical device to profile.
• pInfo is a pointer to a VkAcquireProfilingLockInfoKHR structure which contains information about how the profiling is to be acquired.

Implementations may allow multiple actors to hold the profiling lock concurrently.

Valid Usage (Implicit)

• device must be a valid VkDevice handle
• pInfo must be a valid pointer to a valid VkAcquireProfilingLockInfoKHR structure

Return Codes

Success
• VK_SUCCESS

Failure
• VK_TIMEOUT

The VkAcquireProfilingLockInfoKHR structure is defined as:

typedef struct VkAcquireProfilingLockInfoKHR {
    VkStructureType sType;
    const void* pNext;
    VkAcquireProfilingLockFlagsKHR flags;
    uint64_t timeout;
} VkAcquireProfilingLockInfoKHR;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• flags is reserved for future use.
• timeout indicates how long the function waits, in nanoseconds, if the profiling lock is not available.

Valid Usage (Implicit)

• sType must be VK_STRUCTURE_TYPE_ACQUIRE_PROFILING_LOCK_INFO_KHR
• pNext must be NULL
• flags must be 0

If timeout is 0, vkAcquireProfilingLockKHR will not block while attempting to acquire the profiling lock. If timeout is UINT64_MAX, the function will not return until the profiling lock was acquired.
typedef enum VkAcquireProfilingLockFlagBitsKHR {
} VkAcquireProfilingLockFlagBitsKHR;

typedef VkFlags VkAcquireProfilingLockFlagsKHR;

VkAcquireProfilingLockFlagsKHR is a bitmask type for setting a mask, but is currently reserved for future use.

To release the profiling lock, call:

```c
void vkReleaseProfilingLockKHR(
    VkDevice device);
```

- `device` is the logical device to cease profiling on.

**Valid Usage**

- The profiling lock of `device` must have been held via a previous successful call to `vkAcquireProfilingLockKHR`.

**Valid Usage (Implicit)**

- `device` must be a valid `VkDevice` handle.

17.7. Transform Feedback Queries

Transform feedback queries track the number of primitives attempted to be written and actually written, by the vertex stream being captured, to a transform feedback buffer. This query is updated during draw commands while transform feedback is active. The number of primitives actually written will be less than the number attempted to be written if the bound transform feedback buffer size was too small for the number of primitives actually drawn. Primitives are not written beyond the bound range of the transform feedback buffer. A transform feedback query is begun and ended by calling `vkCmdBeginQuery` and `vkCmdEndQuery`, respectively to query for vertex stream zero. `vkCmdBeginQueryIndexedEXT` and `vkCmdEndQueryIndexedEXT` can be used to begin and end transform feedback queries for any supported vertex stream. When a transform feedback query begins, the count of primitives written and primitives needed starts from zero. For each drawing command, the count is incremented as vertex attribute outputs are captured to the transform feedback buffers while transform feedback is active.

When a transform feedback query finishes, the result for that query is marked as available. The application can then either copy the result to a buffer (via `vkCmdCopyQueryPoolResults`) or request it be put into host memory (via `vkGetQueryPoolResults`).
17.8. Intel performance queries

Intel performance queries allow an application to capture performance data for a set of commands. Performance queries are used in a similar way than other types of queries. A main difference with existing queries is that the resulting data should be handed over to a library capable to produce human readable results rather than being read directly by an application.

Prior to creating a performance query pool, initialize the device for performance queries with the call:

```c
VkResult vkInitializePerformanceApiINTEL(
    VkDevice                                    device,
    const VkInitializePerformanceApiInfoINTEL*  pInitializeInfo);
```

- `device` is the logical device used for the queries.
- `pInitializeInfo` is a pointer to a `VkInitializePerformanceApiInfoINTEL` structure specifying initialization parameters.

**Valid Usage (Implicit)**

- `device` **must** be a valid `VkDevice` handle
- `pInitializeInfo` **must** be a valid pointer to a valid `VkInitializePerformanceApiInfoINTEL` structure

**Return Codes**

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_TOO_MANY_OBJECTS`
- `VK_ERROR_OUT_OF_HOST_MEMORY`

The `VkInitializePerformanceApiInfoINTEL` structure is defined as:

```c
typedef struct VkInitializePerformanceApiInfoINTEL {
    VkStructureType sType;
    const void* pNext;
    void* pUserData;
} VkInitializePerformanceApiInfoINTEL;
```

- `sType` is the type of this structure.
- `pNext` is **NULL** or a pointer to an extension-specific structure.
• `pUserData` is a pointer for application data.

**Valid Usage (Implicit)**

- `sType` **must** be `VK_STRUCTURE_TYPE_INITIALIZE_PERFORMANCE_API_INFO_INTEL`
- `pNext` **must** be `NULL`

Once performance query operations have completed, uninitialize the device for performance queries with the call:

```c
void vkUninitializePerformanceApiINTEL(
    VkDevice device);
```

- `device` is the logical device used for the queries.

**Valid Usage (Implicit)**

- `device` **must** be a valid `VkDevice` handle

Some performance query features of a device can be discovered with the call:

```c
VkResult vkGetPerformanceParameterINTEL(
    VkDevice device,
    VkPerformanceParameterTypeINTEL parameter,
    VkPerformanceValueINTEL* pValue);
```

- `device` is the logical device to query.
- `parameter` is the parameter to query.
- `pValue` is a pointer to a `VkPerformanceValueINTEL` structure in which the type and value of the parameter are returned.

**Valid Usage (Implicit)**

- `device` **must** be a valid `VkDevice` handle
- `parameter` **must** be a valid `VkPerformanceParameterTypeINTEL` value
- `pValue` **must** be a valid pointer to a `VkPerformanceValueINTEL` structure
**Return Codes**

**Success**
- `VK_SUCCESS`

**Failure**
- `VK_ERROR_TOO_MANY_OBJECTS`
- `VK_ERROR_OUT_OF_HOST_MEMORY`

Possible values of `vkGetPerformanceParameterINTEL::parameter`, specifying a performance query feature, are:

```c
typedef enum VkPerformanceParameterTypeINTEL {
    VK_PERFORMANCE_PARAMETER_TYPE_HW_COUNTERS_SUPPORTED_INTEL = 0,
    VK_PERFORMANCE_PARAMETER_TYPE_STREAM_MARKER_VALID_BITS_INTEL = 1,
} VkPerformanceParameterTypeINTEL;
```

- `VK_PERFORMANCE_PARAMETER_TYPE_HW_COUNTERS_SUPPORTED_INTEL` has a boolean result which tells whether hardware counters can be captured.
- `VK_PERFORMANCE_PARAMETER_TYPE_STREAM_MARKER_VALID_BITS_INTEL` has a 32 bits integer result which tells how many bits can be written into the `VkPerformanceValueINTEL` value.

The `VkPerformanceValueINTEL` structure is defined as:

```c
typedef struct VkPerformanceValueINTEL {
    VkPerformanceValueTypeINTEL type;
    VkPerformanceValueDataINTEL data;
} VkPerformanceValueINTEL;
```

- `type` is a `VkPerformanceValueTypeINTEL` value specifying the type of the returned data.
- `data` is a `VkPerformanceValueDataINTEL` union specifying the value of the returned data.

**Valid Usage (Implicit)**

- `type` must be a valid `VkPerformanceValueTypeINTEL` value
- `data` must be a valid `VkPerformanceValueDataINTEL` union

Possible values of `VkPerformanceValueINTEL::type`, specifying the type of the data returned in `VkPerformanceValueINTEL::data`, are:

- `VK_PERFORMANCE_VALUE_TYPE_UINT32_INTEL` specifies that unsigned 32-bit integer data is returned in `data.value32`.
- `VK_PERFORMANCE_VALUE_TYPE_UINT64_INTEL` specifies that unsigned 64-bit integer data is returned
• **VK_PERFORMANCE_VALUE_TYPE_FLOAT_INTEL** specifies that floating-point data is returned in `data.valueFloat`.

• **VK_PERFORMANCE_VALUE_TYPE_BOOL_INTEL** specifies that `Bool32` data is returned in `data.valueBool`.

• **VK_PERFORMANCE_VALUE_TYPE_STRING_INTEL** specifies that a pointer to a null-terminated UTF-8 string is returned in `data.valueString`. The pointer is valid for the lifetime of the `device` parameter passed to `vkGetPerformanceParameterINTEL`.

```c
typedef enum VkPerformanceValueTypeINTEL {
    VK_PERFORMANCE_VALUE_TYPE_UINT32_INTEL = 0,
    VK_PERFORMANCE_VALUE_TYPE_UINT64_INTEL = 1,
    VK_PERFORMANCE_VALUE_TYPE_FLOAT_INTEL = 2,
    VK_PERFORMANCE_VALUE_TYPE_BOOL_INTEL = 3,
    VK_PERFORMANCE_VALUE_TYPE_STRING_INTEL = 4,
} VkPerformanceValueTypeINTEL;
```

The `VkPerformanceValueDataINTEL` union is defined as:

```c
typedef union VkPerformanceValueDataINTEL {
    uint32_t       value32;
    uint64_t       value64;
    float          valueFloat;
    VkBool32       valueBool;
    const char*    valueString;
} VkPerformanceValueDataINTEL;
```

• `data.value32` represents 32-bit integer data.

• `data.value64` represents 64-bit integer data.

• `data.valueFloat` represents floating-point data.

• `data.valueBool` represents `Bool32` data.

• `data.valueString` represents a pointer to a null-terminated UTF-8 string.

The correct member of the union is determined by the associated `VkPerformanceValueTypeINTEL` value.

---

**Valid Usage (Implicit)**

• `valueString` must be a null-terminated UTF-8 string

The `VkQueryPoolPerformanceQueryCreateInfoINTEL` structure is defined as:
```c
typedef struct VkQueryPoolPerformanceQueryCreateInfoINTEL {
    VkStructureType   sType;
    const void*       pNext;
    VkQueryPoolSamplingModeINTEL performanceCountersSampling;
} VkQueryPoolPerformanceQueryCreateInfoINTEL;
```

To create a pool for Intel performance queries, set `VkQueryPoolCreateInfo::queryType` to `VK_QUERY_TYPE_PERFORMANCE_QUERY_INTEL` and add a `VkQueryPoolPerformanceQueryCreateInfoINTEL` structure to the `pNext` chain of the `VkQueryPoolCreateInfo` structure.

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
- `performanceCountersSampling` describe how performance queries should be captured.

### Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_QUERY_POOL_PERFORMANCE_QUERY_CREATE_INFO_INTEL`
- `performanceCountersSampling` must be a valid `VkQueryPoolSamplingModeINTEL` value

Possible values of `VkQueryPoolPerformanceQueryCreateInfoINTEL::performanceCountersSampling` are:

```c
typedef enum VkQueryPoolSamplingModeINTEL {
    VK_QUERY_POOL_SAMPLING_MODE_MANUAL_INTEL = 0,
} VkQueryPoolSamplingModeINTEL;
```

- `VK_QUERY_POOL_SAMPLING_MODE_MANUAL_INTEL` is the default mode in which the application calls `vkCmdBeginQuery` and `vkCmdEndQuery` to record performance data.

To help associate query results with a particular point at which an application emitted commands, markers can be set into the command buffers with the call:

```c
VkResult vkCmdSetPerformanceMarkerINTEL(
    VkCommandBuffer   commandBuffer,
    const VkPerformanceMarkerInfoINTEL* pMarkerInfo);
```

The last marker set onto a command buffer before the end of a query will be part of the query result.
Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `pMarkerInfo` must be a valid pointer to a valid `VkPerformanceMarkerInfoINTEL` structure
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics, compute, or transfer operations

Host Synchronization

- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Both</td>

<td></td>
<td>Transfer</td>
<td></td>
</tr>
</tbody>
</table>

Return Codes

Success

- `VK_SUCCESS`

Failure

- `VK_ERROR_TOO_MANY_OBJECTS`
- `VK_ERROR_OUT_OF_HOST_MEMORY`

The `VkPerformanceMarkerInfoINTEL` structure is defined as:

```c
typedef struct VkPerformanceMarkerInfoINTEL {
    VkStructureType    sType;
    const void*        pNext;
    uint64_t           marker;
} VkPerformanceMarkerInfoINTEL;
```

- `sType` is the type of this structure.
- `pNext` is `NULL` or a pointer to an extension-specific structure.
• **marker** is the marker value that will be recorded into the opaque query results.

**Valid Usage (Implicit)**

- **sType** must be `VK_STRUCTURE_TYPE_PERFORMANCE_MARKER_INFO_INTEL`
- **pNext** must be `NULL`

When monitoring the behavior of an application within the dataset generated by the entire set of applications running on the system, it is useful to identify draw calls within a potentially huge amount of performance data. To do so, application can generate stream markers that will be used to trace back a particular draw call with a particular performance data item.

```c
VkResult vkCmdSetPerformanceStreamMarkerINTEL(
    VkCommandBuffer                             commandBuffer,
    const VkPerformanceStreamMarkerInfoINTEL*   pMarkerInfo);
```

**Valid Usage (Implicit)**

- **commandBuffer** must be a valid `VkCommandBuffer` handle
- **pMarkerInfo** must be a valid pointer to a valid `VkPerformanceStreamMarkerInfoINTEL` structure
- **commandBuffer** must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics, compute, or transfer operations

**Host Synchronization**

- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

**Command Properties**

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Both</td>
<td>Graphics</td>
<td></td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td>Compute</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Transfer</td>
<td></td>
</tr>
</tbody>
</table>
**Return Codes**

**Success**
- VK_SUCCESS

**Failure**
- VK_ERROR_TOO_MANY_OBJECTS
- VK_ERROR_OUT_OF_HOST_MEMORY

The `VkPerformanceStreamMarkerInfoINTEL` structure is defined as:

```c
typedef struct VkPerformanceStreamMarkerInfoINTEL {
    VkStructureType sType;
    const void* pNext;
    uint32_t marker;
} VkPerformanceStreamMarkerInfoINTEL;
```

- `sType` is the type of this structure.
- `pNext` is NULL or a pointer to an extension-specific structure.
- `marker` is the marker value that will be recorded into the reports consumed by an external application.

**Valid Usage**
- The value written by the application into `marker` must only used the valid bits as reported by `vkGetPerformanceParameterINTEL` with `VK_PERFORMANCE_PARAMETER_TYPE_STREAM_MARKER_VALID_BITS_INTEL`.

**Valid Usage (Implicit)**
- `sType` must be `VK_STRUCTURE_TYPE_PERFORMANCE_STREAM_MARKER_INFO_INTEL`
- `pNext` must be NULL

Some applications might want measure the effect of a set of commands with a different settings. It is possible to override a particular settings using:

```c
VkResult vkCmdSetPerformanceOverrideINTEL(
    VkCommandBuffer commandBuffer,   // commandBuffer is the command buffer where the override takes place.
    const VkPerformanceOverrideInfoINTEL* pOverrideInfo);
```
• **pOverrideInfo** is a pointer to a **VkPerformanceOverrideInfoINTEL** structure selecting the parameter to override.

### Valid Usage

• **pOverrideInfo must** not be used with a **VkPerformanceOverrideTypeINTEL** that is not reported available by **vkGetPerformanceParameterINTEL**

### Valid Usage (Implicit)

• **commandBuffer must** be a valid **VkCommandBuffer** handle
• **pOverrideInfo must** be a valid pointer to a valid **VkPerformanceOverrideInfoINTEL** structure
• **commandBuffer must** be in the **recording state**
• The **VkCommandPool** that **commandBuffer** was allocated from **must** support graphics, compute, or transfer operations

### Host Synchronization

• Host access to the **VkCommandPool** that **commandBuffer** was allocated from **must** be externally synchronized

### Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Both</td>
<td>Graphics, Compute, Transfer</td>
<td></td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Return Codes

**Success**

• **VK_SUCCESS**

**Failure**

• **VK_ERROR_TOO_MANY_OBJECTS**
• **VK_ERROR_OUT_OF_HOST_MEMORY**

The **VkPerformanceOverrideInfoINTEL** structure is defined as:
typedef struct VkPerformanceOverrideInfoINTEL {
    VkStructureType                   sType;
    const void*                       pNext;
    VkPerformanceOverrideTypeINTEL    type;
    VkBool32                          enable;
    uint64_t                          parameter;
} VkPerformanceOverrideInfoINTEL;

• **type** is the particular `VkPerformanceOverrideTypeINTEL` to set.
• **enable** defines whether the override is enabled.
• **parameter** is a potential required parameter for the override.

### Valid Usage (Implicit)

• **sType** must be `VK_STRUCTURE_TYPE_PERFORMANCE_OVERRIDE_INFO_INTEL`
• **pNext** must be `NULL`
• **type** must be a valid `VkPerformanceOverrideTypeINTEL` value

Possible values of `VkPerformanceOverrideInfoINTEL::type`, specifying performance override types, are:

```c
typedef enum VkPerformanceOverrideTypeINTEL {
    VK_PERFORMANCE_OVERRIDE_TYPE_NULL_HARDWARE_INTEL = 0,
    VK_PERFORMANCE_OVERRIDE_TYPE_FLUSH_GPU_CACHES_INTEL = 1,
} VkPerformanceOverrideTypeINTEL;
```

• **VK_PERFORMANCE_OVERRIDE_TYPE_NULL_HARDWARE_INTEL** turns all rendering operations into noop.
• **VK_PERFORMANCE_OVERRIDE_TYPE_FLUSH_GPU_CACHES_INTEL** stalls the stream of commands until all previously emitted commands have completed and all caches been flushed and invalidated.

Before submitting command buffers containing performance queries commands to a device queue, the application must acquire and set a performance query configuration. The configuration can be released once all command buffers containing performance query commands are not in a pending state.

```c
VK_DEFINE_NON_DISPATCHABLE_HANDLE(VkPerformanceConfigurationINTEL)
```

To acquire a device performance configuration, call:
VkResult vkAcquirePerformanceConfigurationINTEL(
    VkDevice device,
    const VkPerformanceConfigurationAcquireInfoINTEL* pAcquireInfo,
    VkPerformanceConfigurationINTEL* pConfiguration);

• device is the logical device that the performance query commands will be submitted to.
• pAcquireInfo is a pointer to a VkPerformanceConfigurationAcquireInfoINTEL structure, specifying the performance configuration to acquire.
• pConfiguration is a pointer to a VkPerformanceConfigurationINTEL handle in which the resulting configuration object is returned.

Valid Usage (Implicit)

• device must be a valid VkDevice handle
• pAcquireInfo must be a valid pointer to a valid VkPerformanceConfigurationAcquireInfoINTEL structure
• pConfiguration must be a valid pointer to a VkPerformanceConfigurationINTEL handle

Return Codes

Success
• VK_SUCCESS

Failure
• VK_ERROR_TOO_MANY_OBJECTS
• VK_ERROR_OUT_OF_HOST_MEMORY

The VkPerformanceConfigurationAcquireInfoINTEL structure is defined as:

typedef struct VkPerformanceConfigurationAcquireInfoINTEL {
    VkStructureType sType;
    const void* pNext;
    VkPerformanceConfigurationTypeINTEL type;
} VkPerformanceConfigurationAcquireInfoINTEL;

• sType is the type of this structure.
• pNext is NULL or a pointer to an extension-specific structure.
• type is one of the VkPerformanceConfigurationTypeINTEL type of performance configuration that will be acquired.
Valid Usage (Implicit)

- `sType` must be `VK_STRUCTURE_TYPE_PERFORMANCE_CONFIGURATION_ACQUIRE_INFO_INTEL`
- `pNext` must be `NULL`
- `type` must be a valid `VkPerformanceConfigurationTypeINTEL` value

Possible values of `VkPerformanceConfigurationAcquireInfoINTEL::type`, specifying performance configuration types, are:

```c
typedef enum VkPerformanceConfigurationTypeINTEL {
    VK_PERFORMANCE_CONFIGURATION_TYPE_COMMAND_QUEUE_METRICS_DISCOVERY_ACTIVATED_INTEL = 0,
} VkPerformanceConfigurationTypeINTEL;
```

To set a performance configuration, call:

```c
VkResult vkQueueSetPerformanceConfigurationINTEL(
    VkQueue queue,
    VkPerformanceConfigurationINTEL configuration);
```

- `queue` is the queue on which the configuration will be used.
- `configuration` is the configuration to use.

Valid Usage (Implicit)

- `queue` must be a valid `VkQueue` handle
- `configuration` must be a valid `VkPerformanceConfigurationINTEL` handle
- Both of `configuration`, and `queue` must have been created, allocated, or retrieved from the same `VkDevice`

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>Any</td>
<td>-</td>
</tr>
</tbody>
</table>
To release a device performance configuration, call:

```c
VkResult vkReleasePerformanceConfigurationINTEL(
    VkDevice device,                     
    VkPerformanceConfigurationINTEL    configuration);
```

- `device` is the device associated to the configuration object to release.
- `configuration` is the configuration object to release.

**Valid Usage**

- `configuration` **must** not be released before all command buffers submitted while the configuration was set are in **pending state**

**Valid Usage (Implicit)**

- `device` **must** be a valid `VkDevice` handle
- `configuration` **must** be a valid `VkPerformanceConfigurationINTEL` handle
- `configuration` **must** have been created, allocated, or retrieved from `device`

**Return Codes**

**Success**

- `VK_SUCCESS`

**Failure**

- `VK_ERROR_TOO_MANY_OBJECTS`
- `VK_ERROR_OUT_OF_HOST_MEMORY`
Chapter 18. Clear Commands

18.1. Clearing Images Outside A Render Pass Instance

Color and depth/stencil images can be cleared outside a render pass instance using `vkCmdClearColorImage` or `vkCmdClearDepthStencilImage`, respectively. These commands are only allowed outside of a render pass instance.

To clear one or more subranges of a color image, call:

```c
void vkCmdClearColorImage(
    VkCommandBuffer                             commandBuffer,
    VkImage                                     image,
    VkImageLayout                               imageLayout,
    const VkClearColorValue*                    pColor,
    uint32_t                                    rangeCount,
    const VkImageSubresourceRange*              pRanges);
```

- `commandBuffer` is the command buffer into which the command will be recorded.
- `image` is the image to be cleared.
- `imageLayout` specifies the current layout of the image subresource ranges to be cleared, and must be `VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR`, `VK_IMAGE_LAYOUT_GENERAL` or `VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL`.
- `pColor` is a pointer to a `VkClearColorValue` structure containing the values that the image subresource ranges will be cleared to (see Clear Values below).
- `rangeCount` is the number of image subresource range structures in `pRanges`.
- `pRanges` is a pointer to an array of `VkImageSubresourceRange` structures describing a range of mipmap levels, array layers, and aspects to be cleared, as described in Image Views.

Each specified range in `pRanges` is cleared to the value specified by `pColor`. 
Valid Usage

- The format features of image must contain VK_FORMAT_FEATURE_TRANSFER_DST_BIT
- image must have been created with VK_IMAGE_USAGE_TRANSFER_DST_BIT usage flag
- image must not use a format listed in Formats requiring sampler YCbCr conversion for VK_IMAGE_ASPECT_COLOR_BIT image views
- If image is non-sparse then it must be bound completely and contiguously to a single VkDeviceMemory object
- imageLayout must specify the layout of the image subresource ranges of image specified in pRanges at the time this command is executed on a VkDevice
- imageLayout must be VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL, VK_IMAGE_LAYOUT_GENERAL, or VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR
- The VkImageSubresourceRange::aspectMask members of the elements of the pRanges array must each only include VK_IMAGE_ASPECT_COLOR_BIT
- The VkImageSubresourceRange::baseMipLevel members of the elements of the pRanges array must each be less than the mipLevels specified in VkImageCreateInfo when image was created
- For each VkImageSubresourceRange element of pRanges, if the levelCount member is not VK_REMAINING_MIP_LEVELS, then baseMipLevel + levelCount must be less than the mipLevels specified in VkImageCreateInfo when image was created
- The VkImageSubresourceRange::baseArrayLayer members of the elements of the pRanges array must each be less than the arrayLayers specified in VkImageCreateInfo when image was created
- For each VkImageSubresourceRange element of pRanges, if the layerCount member is not VK_REMAINING_ARRAY_LAYERS, then baseArrayLayer + layerCount must be less than the arrayLayers specified in VkImageCreateInfo when image was created
- image must not have a compressed or depth/stencil format
Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `image` must be a valid `VkImage` handle
- `imageLayout` must be a valid `VkImageLayout` value
- `pColor` must be a valid pointer to a valid `VkClearColorValue` union
- `pRanges` must be a valid pointer to an array of `rangeCount` valid `VkImageSubresourceRange` structures
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics, or compute operations
- This command must only be called outside of a render pass instance
- `rangeCount` must be greater than 0
- Both of `commandBuffer`, and `image` must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Outside</td>
<td>Graphics</td>
<td>Transfer</td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td>Compute</td>
<td></td>
</tr>
</tbody>
</table>

To clear one or more subranges of a depth/stencil image, call:

```c
void vkCmdClearDepthStencilImage(
    VkCommandBuffer                             commandBuffer,
    VkImage                                     image,
    VkImageLayout                               imageLayout,
    const VkClearColorValue*                   pDepthStencil,
    uint32_t                                    rangeCount,
    const VkImageSubresourceRange*             pRanges);
```
• **commandBuffer** is the command buffer into which the command will be recorded.

• **image** is the image to be cleared.

• **imageLayout** specifies the current layout of the image subresource ranges to be cleared, and **must** be `VK_IMAGE_LAYOUT_GENERAL` or `VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL`.

• **pDepthStencil** is a pointer to a `VkClearDepthStencilValue` structure containing the values that the depth and stencil image subresource ranges will be cleared to (see [Clear Values](#) below).

• **rangeCount** is the number of image subresource range structures in **pRanges**.

• **pRanges** is a pointer to an array of `VkImageSubresourceRange` structures describing a range of mipmap levels, array layers, and aspects to be cleared, as described in [Image Views](#).
Valid Usage

- The format features of image must contain VK_FORMAT_FEATURE_TRANSFER_DST_BIT.

- If the aspect member of any element of pRanges includes VK_IMAGE_ASPECT_STENCIL_BIT, and image was created with separate stencil usage, VK_IMAGE_USAGE_TRANSFER_DST_BIT must have been included in the VkImageStencilUsageCreateInfo::stencilUsage used to create image.

- If the aspect member of any element of pRanges includes VK_IMAGE_ASPECT_STENCIL_BIT, and image was not created with separate stencil usage, VK_IMAGE_USAGE_TRANSFER_DST_BIT must have been included in the VkImageCreateInfo::usage used to create image.

- If the aspect member of any element of pRanges includes VK_IMAGE_ASPECT_DEPTH_BIT, VK_IMAGE_USAGE_TRANSFER_DST_BIT must have been included in the VkImageCreateInfo::usage used to create image.

- If image is non-sparse then it must be bound completely and contiguously to a single VkDeviceMemory object.

- imageLayout must specify the layout of the image subresource ranges of image specified in pRanges at the time this command is executed on a VkDevice.

- imageLayout must be either of VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL or VK_IMAGE_LAYOUT_GENERAL.

- The VkImageSubresourceRange::aspectMask member of each element of the pRanges array must not include bits other than VK_IMAGE_ASPECT_DEPTH_BIT or VK_IMAGE_ASPECT_STENCIL_BIT.

- If the image’s format does not have a stencil component, then the VkImageSubresourceRange::aspectMask member of each element of the pRanges array must not include the VK_IMAGE_ASPECT_STENCIL_BIT bit.

- If the image’s format does not have a depth component, then the VkImageSubresourceRange::aspectMask member of each element of the pRanges array must not include the VK_IMAGE_ASPECT_DEPTH_BIT bit.

- The VkImageSubresourceRange::baseMipLevel members of the elements of the pRanges array must each be less than the mipLevels specified in VkImageCreateInfo when image was created.

- For each VkImageSubresourceRange element of pRanges, if the levelCount member is not VK_REMAINING_MIP_LEVELS, then baseMipLevel + levelCount must be less than the mipLevels specified in VkImageCreateInfo when image was created.

- The VkImageSubresourceRange::baseArrayLayer members of the elements of the pRanges array must each be less than the arrayLayers specified in VkImageCreateInfo when image was created.

- For each VkImageSubresourceRange element of pRanges, if the layerCount member is not VK_REMAINING_ARRAY_LAYERS, then baseArrayLayer + layerCount must be less than the arrayLayers specified in VkImageCreateInfo when image was created.

- image must have a depth/stencil format.
Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `image` must be a valid `VkImage` handle
- `imageLayout` must be a valid `VkImageLayout` value
- `pDepthStencil` must be a valid pointer to a valid `VkClearDepthStencilValue` structure
- `pRanges` must be a valid pointer to an array of `rangeCount` valid `VkImageSubresourceRange` structures
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support graphics operations
- This command must only be called outside of a render pass instance
- `rangeCount` must be greater than 0
- Both of `commandBuffer`, and `image` must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Clears outside render pass instances are treated as transfer operations for the purposes of memory barriers.

18.2. Clearing Images Inside A Render Pass Instance

To clear one or more regions of color and depth/stencil attachments inside a render pass instance, call:
void vkCmdClearAttachments(
    VkCommandBuffer                             commandBuffer,
    uint32_t                                    attachmentCount,
    const VkClearAttachment*                    pAttachments,
    uint32_t                                    rectCount,
    const VkClearRect*                          pRects);

• commandBuffer is the command buffer into which the command will be recorded.
• attachmentCount is the number of entries in the pAttachments array.
• pAttachments is a pointer to an array of VkClearAttachment structures defining the attachments to clear and the clear values to use. If any attachment to be cleared in the current subpass is VK_ATTACHMENT_UNUSED, then the clear has no effect on that attachment.
• rectCount is the number of entries in the pRects array.
• pRects is a pointer to an array of VkClearRect structures defining regions within each selected attachment to clear.

vkCmdClearAttachments can clear multiple regions of each attachment used in the current subpass of a render pass instance. This command must be called only inside a render pass instance, and implicitly selects the images to clear based on the current framebuffer attachments and the command parameters.

If the render pass has a fragment density map attachment, clears follow the operations of fragment density maps as if each clear region was a primitive which generates fragments. The clear color is applied to all pixels inside each fragment’s area regardless if the pixels lie outside of the clear region. Clears may have a different set of supported fragment areas than draws.

Unlike other clear commands, vkCmdClearAttachments executes as a drawing command, rather than a transfer command, with writes performed by it executing in rasterization order. Clears to color attachments are executed as color attachment writes, by the VK_PIPELINE_STAGE_COLOR_ATTACHMENT_OUTPUT_BIT stage. Clears to depth/stencil attachments are executed as depth writes and writes by the VK_PIPELINE_STAGE_EARLY_FRAGMENT_TESTS_BIT and VK_PIPELINE_STAGE_LATE_FRAGMENT_TESTS_BIT stages.
Valid Usage

- If the aspectMask member of any element of pAttachments contains VK_IMAGE_ASPECT_COLOR_BIT, then the colorAttachment member of that element must either refer to a color attachment which is VK_ATTACHMENT_UNUSED, or must be a valid color attachment.

- If the aspectMask member of any element of pAttachments contains VK_IMAGE_ASPECT_DEPTH_BIT, then the current subpass' depth/stencil attachment must either be VK_ATTACHMENT_UNUSED, or must have a depth component.

- If the aspectMask member of any element of pAttachments contains VK_IMAGE_ASPECT_STENCIL_BIT, then the current subpass' depth/stencil attachment must either be VK_ATTACHMENT_UNUSED, or must have a stencil component.

- The rect member of each element of pRects must have an extent.width greater than 0.

- The rect member of each element of pRects must have an extent.height greater than 0.

- The rectangular region specified by each element of pRects must be contained within the render area of the current render pass instance.

- The layers specified by each element of pRects must be contained within every attachment that pAttachments refers to.

- The layerCount member of each element of pRects must not be 0.

- If the render pass instance this is recorded in uses multiview, then baseArrayLayer must be zero and layerCount must be one.

Valid Usage (Implicit)

- commandBuffer must be a valid VkCommandBuffer handle.

- pAttachments must be a valid pointer to an array of attachmentCount valid VkClearAttachment structures.

- pRects must be a valid pointer to an array of rectCount VkClearRect structures.

- commandBuffer must be in the recording state.

- The VkCommandPool that commandBuffer was allocated from must support graphics operations.

- This command must only be called inside of a render pass instance.

- attachmentCount must be greater than 0.

- rectCount must be greater than 0.
Host Synchronization

- Host access to `commandBuffer` must be externally synchronized.
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized.

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Inside</td>
<td>Graphics</td>
<td>Graphics</td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The `VkClearRect` structure is defined as:

```c
typedef struct VkClearRect {
    VkRect2D    rect;
    uint32_t    baseArrayLayer;
    uint32_t    layerCount;
} VkClearRect;
```

- `rect` is the two-dimensional region to be cleared.
- `baseArrayLayer` is the first layer to be cleared.
- `layerCount` is the number of layers to clear.

The layers `[baseArrayLayer, baseArrayLayer + layerCount)` counting from the base layer of the attachment image view are cleared.

The `VkClearAttachment` structure is defined as:

```c
typedef struct VkClearAttachment {
    VkImageAspectFlags    aspectMask;
    uint32_t              colorAttachment;
    VkClearValue          clearValue;
} VkClearAttachment;
```

- `aspectMask` is a mask selecting the color, depth and/or stencil aspects of the attachment to be cleared.
- `colorAttachment` is only meaningful if `VK_IMAGE_ASPECT_COLOR_BIT` is set in `aspectMask`, in which case it is an index to the `pColorAttachments` array in the `VkSubpassDescription` structure of the current subpass which selects the color attachment to clear.
- `clearValue` is the color or depth/stencil value to clear the attachment to, as described in `Clear`
Values below.

No memory barriers are needed between \texttt{vkCmdClearAttachments} and preceding or subsequent draw or attachment clear commands in the same subpass.

The \texttt{vkCmdClearAttachments} command is not affected by the bound pipeline state.

Attachments can also be cleared at the beginning of a render pass instance by setting loadOp (or stencilLoadOp) of \texttt{VkAttachmentDescription} to \texttt{VK_ATTACHMENT_LOAD_OP_CLEAR}, as described for \texttt{vkCreateRenderPass}.

### Valid Usage

- If aspectMask includes \texttt{VK_IMAGE_ASPECT_COLOR_BIT}, it \textbf{must} not include \texttt{VK_IMAGE_ASPECT_DEPTH_BIT} or \texttt{VK_IMAGE_ASPECT_STENCIL_BIT}
- \textbf{aspectMask must} not include \texttt{VK_IMAGE_ASPECT_METADATA_BIT}
- \textbf{aspectMask must} not include \texttt{VK_IMAGE_ASPECT_MEMORY_PLANE_i_BIT_EXT} for any index \(i\)
- \textbf{clearValue must} be a valid \texttt{VkClearValue} union

### Valid Usage (Implicit)

- \textbf{aspectMask must} be a valid combination of \texttt{VkImageAspectFlagBits} values
- \textbf{aspectMask must} not be 0

### 18.3. Clear Values

The \texttt{VkClearColorValue} structure is defined as:

```c
typedef union VkClearColorValue {
    float     float32[4];
    int32_t   int32[4];
    uint32_t  uint32[4];
} VkClearColorValue;
```

- \texttt{float32} are the color clear values when the format of the image or attachment is one of the formats in the \texttt{Interpretation of Numeric Format} table other than signed integer (\texttt{SINT}) or unsigned integer (\texttt{UINT}). Floating point values are automatically converted to the format of the image, with the clear value being treated as linear if the image is sRGB.

- \texttt{int32} are the color clear values when the format of the image or attachment is signed integer (\texttt{SINT}). Signed integer values are converted to the format of the image by casting to the smaller type (with negative 32-bit values mapping to negative values in the smaller type). If the integer clear value is not representable in the target type (e.g. would overflow in conversion to that type), the clear value is undefined.
• `uint32` are the color clear values when the format of the image or attachment is unsigned integer (`UINT`). Unsigned integer values are converted to the format of the image by casting to the integer type with fewer bits.

The four array elements of the clear color map to R, G, B, and A components of image formats, in order.

If the image has more than one sample, the same value is written to all samples for any pixels being cleared.

The `VkClearDepthStencilValue` structure is defined as:

```c
typedef struct VkClearDepthStencilValue {
    float depth;
    uint32_t stencil;
} VkClearDepthStencilValue;
```

• `depth` is the clear value for the depth aspect of the depth/stencil attachment. It is a floating-point value which is automatically converted to the attachment's format.

• `stencil` is the clear value for the stencil aspect of the depth/stencil attachment. It is a 32-bit integer value which is converted to the attachment's format by taking the appropriate number of LSBs.

**Valid Usage**

• Unless the `VK_EXT_depth_range_unrestricted` extension is enabled `depth` must be between 0.0 and 1.0, inclusive.

The `VkClearValue` union is defined as:

```c
typedef union VkClearValue {
    VkClearColorValue color;
    VkClearDepthStencilValue depthStencil;
} VkClearValue;
```

• `color` specifies the color image clear values to use when clearing a color image or attachment.

• `depthStencil` specifies the depth and stencil clear values to use when clearing a depth/stencil image or attachment.

This union is used where part of the API requires either color or depth/stencil clear values, depending on the attachment, and defines the initial clear values in the `VkRenderPassBeginInfo` structure.
18.4. Filling Buffers

To clear buffer data, call:

```c
void vkCmdFillBuffer(
    VkCommandBuffer                             commandBuffer,
    VkBuffer                                    dstBuffer,
    VkDeviceSize                                dstOffset,
    VkDeviceSize                                size,
    uint32_t                                    data);
```

- **commandBuffer** is the command buffer into which the command will be recorded.
- **dstBuffer** is the buffer to be filled.
- **dstOffset** is the byte offset into the buffer at which to start filling, and **must** be a multiple of 4.
- **size** is the number of bytes to fill, and **must** be either a multiple of 4, or **VK_WHOLE_SIZE** to fill the range from **offset** to the end of the buffer. If **VK_WHOLE_SIZE** is used and the remaining size of the buffer is not a multiple of 4, then the nearest smaller multiple is used.
- **data** is the 4-byte word written repeatedly to the buffer to fill **size** bytes of data. The data word is written to memory according to the host endianness.

`vkCmdFillBuffer` is treated as “transfer” operation for the purposes of synchronization barriers. The **VK_BUFFER_USAGE_TRANSFER_DST_BIT** must be specified in usage of `VkBufferCreateInfo` in order for the buffer to be compatible with `vkCmdFillBuffer`.

### Valid Usage

- **dstOffset** must be less than the size of **dstBuffer**
- **dstOffset** must be a multiple of 4
- If **size** is not equal to **VK_WHOLE_SIZE**, **size** must be greater than 0
- If **size** is not equal to **VK_WHOLE_SIZE**, **size** must be less than or equal to the size of **dstBuffer** minus **dstOffset**
- If **size** is not equal to **VK_WHOLE_SIZE**, **size** must be a multiple of 4
- **dstBuffer** must have been created with **VK_BUFFER_USAGE_TRANSFER_DST_BIT** usage flag
- If **dstBuffer** is non-sparse then it **must** be bound completely and contiguously to a single `VkDeviceMemory` object
Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `dstBuffer` **must** be a valid `VkBuffer` handle
- `commandBuffer` **must** be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support transfer, graphics or compute operations
- This command **must** only be called outside of a render pass instance
- Both of `commandBuffer`, and `dstBuffer` **must** have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary, Secondary</td>
<td>Outside</td>
<td>Transfer, Graphics, Compute</td>
<td>Transfer</td>
</tr>
</tbody>
</table>

18.5. Updating Buffers

To update buffer data inline in a command buffer, call:

```c
void vkCmdUpdateBuffer(
    VkCommandBuffer commandBuffer, 
    VkBuffer dstBuffer, 
    VkDeviceSize dstOffset, 
    VkDeviceSize dataSize, 
    const void* pData);
```

- `commandBuffer` is the command buffer into which the command will be recorded.
- `dstBuffer` is a handle to the buffer to be updated.
- `dstOffset` is the byte offset into the buffer to start updating, and **must** be a multiple of 4.
• `dataSize` is the number of bytes to update, and **must** be a multiple of 4.
• `pData` is a pointer to the source data for the buffer update, and **must** be at least `dataSize` bytes in size.

`dataSize` **must** be less than or equal to 65536 bytes. For larger updates, applications **can** use buffer to buffer copies.

---

**Note**
Buffer updates performed with `vkCmdUpdateBuffer` first copy the data into command buffer memory when the command is recorded (which requires additional storage and may incur an additional allocation), and then copy the data from the command buffer into `dstBuffer` when the command is executed on a device.

The additional cost of this functionality compared to buffer to buffer copies means it is only recommended for very small amounts of data, and is why it is limited to only 65536 bytes.

Applications **can** work around this by issuing multiple `vkCmdUpdateBuffer` commands to different ranges of the same buffer, but it is strongly recommended that they **should** not.

The source data is copied from the user pointer to the command buffer when the command is called.

`vkCmdUpdateBuffer` is only allowed outside of a render pass. This command is treated as “transfer” operation, for the purposes of synchronization barriers. The **must** be specified in `usage` of `VkBufferCreateInfo` in order for the buffer to be compatible with `vkCmdUpdateBuffer`.

---

**Valid Usage**

- `dstOffset` **must** be less than the size of `dstBuffer`
- `dataSize` **must** be less than or equal to the size of `dstBuffer` minus `dstOffset`
- `dstBuffer` **must** have been created with `VK_BUFFER_USAGE_TRANSFER_DST_BIT` usage flag
- If `dstBuffer` is non-sparse then it **must** be bound completely and contiguously to a single `VkDeviceMemory` object
- `dstOffset` **must** be a multiple of 4
- `dataSize` **must** be less than or equal to 65536
- `dataSize` **must** be a multiple of 4
Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `dstBuffer` **must** be a valid `VkBuffer` handle
- `pData` **must** be a valid pointer to an array of `dataSize` bytes
- `commandBuffer` **must** be in the **recording state**
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support transfer, graphics, or compute operations
- This command **must** only be called outside of a render pass instance
- `dataSize` **must** be greater than 0
- Both of `commandBuffer`, and `dstBuffer` **must** have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Outside</td>
<td>Transfer</td>
<td>Transfer</td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td>Graphics</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Compute</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

The `pData` parameter was of type `uint32_t*` instead of `void*` prior to version 1.0.19 of the Specification and `VK_HEADER_VERSION` 19 of the Vulkan Header Files. This was a historical anomaly, as the source data may be of other types.
Chapter 19. Copy Commands

An application can copy buffer and image data using several methods depending on the type of data transfer. Data can be copied between buffer objects with `vkCmdCopyBuffer` and a portion of an image can be copied to another image with `vkCmdCopyImage`. Image data can also be copied to and from buffer memory using `vkCmdCopyImageToBuffer` and `vkCmdCopyBufferToImage`. Image data can be blitted (with or without scaling and filtering) with `vkCmdBlitImage`. Multisampled images can be resolved to a non-multisampled image with `vkCmdResolveImage`.

19.1. Common Operation

The following valid usage rules apply to all copy commands:

- Copy commands must be recorded outside of a render pass instance.
- The set of all bytes bound to all the source regions must not overlap the set of all bytes bound to the destination regions.
- The set of all bytes bound to each destination region must not overlap the set of all bytes bound to another destination region.
- Copy regions must be non-empty.
- Regions must not extend outside the bounds of the buffer or image level, except that regions of compressed images can extend as far as the dimension of the image level rounded up to a complete compressed texel block.
- Source image subresources must be in either the `VK_IMAGE_LAYOUT_GENERAL` or `VK_IMAGE_LAYOUT_TRANSFER_SRC_OPTIMAL` layout. Destination image subresources must be in the `VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR`, `VK_IMAGE_LAYOUT_GENERAL` or `VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL` layout. As a consequence, if an image subresource is used as both source and destination of a copy, it must be in the `VK_IMAGE_LAYOUT_GENERAL` layout.
- Source images must have `VK_FORMAT_FEATURE_TRANSFER_SRC_BIT` in their format features.
- Destination images must have `VK_FORMAT_FEATURE_TRANSFER_DST_BIT` in their format features.
- Source buffers must have been created with the `VK_BUFFER_USAGE_TRANSFER_SRC_BIT` usage bit enabled and destination buffers must have been created with the `VK_BUFFER_USAGE_TRANSFER_DST_BIT` usage bit enabled.
- If the stencil aspect of source image is accessed, and the source image was not created with separate stencil usage, the source image must have been created with `VK_IMAGE_USAGE_TRANSFER_SRC_BIT` set in `VkImageCreateInfo::usage`.
- If the stencil aspect of destination image is accessed, and the destination image was not created with separate stencil usage, the destination image must have been created with `VK_IMAGE_USAGE_TRANSFER_DST_BIT` set in `VkImageCreateInfo::usage`.
- If the stencil aspect of source image is accessed, and the source image was created with separate stencil usage, the source image must have been created with `VK_IMAGE_USAGE_TRANSFER_SRC_BIT` set in `VkImageStenciUsageCreateInfo::stencilUsage`.
- If the stencil aspect of destination image is accessed, and the destination image was created
with separate stencil usage, the destination image must have been created with
VK_IMAGE_USAGE_TRANSFER_DST_BIT set in VkImageStencilUsageCreateInfo::stencilUsage
• If non-stencil aspects of a source image are accessed, the source image must have been created
with VK_IMAGE_USAGE_TRANSFER_SRC_BIT set in VkImageCreateInfo::usage
• If non-stencil aspects of a source image are accessed, the source image must have been created
with VK_IMAGE_USAGE_TRANSFER_DST_BIT set in VkImageCreateInfo::usage

All copy commands are treated as “transfer” operations for the purposes of synchronization barriers.

All copy commands that have a source format with an X component in its format description read
undefined values from those bits.

All copy commands that have a destination format with an X component in its format description
write undefined values to those bits.

19.2. Copying Data Between Buffers

To copy data between buffer objects, call:

```c
void vkCmdCopyBuffer(
    VkCommandBuffer                                 commandBuffer,
    VkBuffer                                        srcBuffer,
    VkBuffer                                        dstBuffer,
    uint32_t                                        regionCount,
    const VkBufferCopy*                            pRegions);
```

• `commandBuffer` is the command buffer into which the command will be recorded.
• `srcBuffer` is the source buffer.
• `dstBuffer` is the destination buffer.
• `regionCount` is the number of regions to copy.
• `pRegions` is a pointer to an array of VkBufferCopy structures specifying the regions to copy.

Each region in `pRegions` is copied from the source buffer to the same region of the destination
buffer. `srcBuffer` and `dstBuffer` can be the same buffer or alias the same memory, but the resulting
values are undefined if the copy regions overlap in memory.
Valid Usage

• The `srcOffset` member of each element of `pRegions` must be less than the size of `srcBuffer`
• The `dstOffset` member of each element of `pRegions` must be less than the size of `dstBuffer`
• The `size` member of each element of `pRegions` must be less than or equal to the size of `srcBuffer` minus `srcOffset`
• The `size` member of each element of `pRegions` must be less than or equal to the size of `dstBuffer` minus `dstOffset`
• The union of the source regions, and the union of the destination regions, specified by the elements of `pRegions`, must not overlap in memory
• `srcBuffer` must have been created with `VK_BUFFER_USAGE_TRANSFER_SRC_BIT` usage flag
• If `srcBuffer` is non-sparse then it must be bound completely and contiguously to a single `VkDeviceMemory` object
• `dstBuffer` must have been created with `VK_BUFFER_USAGE_TRANSFER_DST_BIT` usage flag
• If `dstBuffer` is non-sparse then it must be bound completely and contiguously to a single `VkDeviceMemory` object

Valid Usage (Implicit)

• `commandBuffer` must be a valid `VkCommandBuffer` handle
• `srcBuffer` must be a valid `VkBuffer` handle
• `dstBuffer` must be a valid `VkBuffer` handle
• `pRegions` must be a valid pointer to an array of `regionCount` valid `VkBufferCopy` structures
• `commandBuffer` must be in the recording state
• The `VkCommandPool` that `commandBuffer` was allocated from must support transfer, graphics, or compute operations
• This command must only be called outside of a render pass instance
• `regionCount` must be greater than 0
• Each of `commandBuffer`, `dstBuffer`, and `srcBuffer` must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

• Host access to `commandBuffer` must be externally synchronized
• Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized
The `VkBufferCopy` structure is defined as:

```c
typedef struct VkBufferCopy {
    VkDeviceSize srcOffset;
    VkDeviceSize dstOffset;
    VkDeviceSize size;
} VkBufferCopy;
```

- `srcOffset` is the starting offset in bytes from the start of `srcBuffer`.
- `dstOffset` is the starting offset in bytes from the start of `dstBuffer`.
- `size` is the number of bytes to copy.

## Valid Usage

- The `size` must be greater than 0.

### 19.3. Copying Data Between Images

`vkCmdCopyImage` performs image copies in a similar manner to a host `memcpy`. It does not perform general-purpose conversions such as scaling, resizing, blending, color-space conversion, or format conversions. Rather, it simply copies raw image data. `vkCmdCopyImage` can copy between images with different formats, provided the formats are compatible as defined below.

To copy data between image objects, call:

```c
void vkCmdCopyImage( 
    VkCommandBuffer commandBuffer, 
    VkImage srcImage, 
    VkImageLayout srcImageLayout, 
    VkImage dstImage, 
    VkImageLayout dstImageLayout, 
    uint32_t regionCount, 
    const VkImageCopy* pRegions); 
```

- `commandBuffer` is the command buffer into which the command will be recorded.
• `srcImage` is the source image.
• `srcImageLayout` is the current layout of the source image subresource.
• `dstImage` is the destination image.
• `dstImageLayout` is the current layout of the destination image subresource.
• `regionCount` is the number of regions to copy.
• `pRegions` is a pointer to an array of `VkImageCopy` structures specifying the regions to copy.

Each region in `pRegions` is copied from the source image to the same region of the destination image. `srcImage` and `dstImage` can be the same image or alias the same memory.

The formats of `srcImage` and `dstImage` must be compatible. Formats are compatible if they share the same class, as shown in the Compatible Formats table. Depth/stencil formats must match exactly.

If the format of `srcImage` or `dstImage` is a multi-planar image format, regions of each plane to be copied must be specified separately using the `srcSubresource` and `dstSubresource` members of the `VkImageCopy` structure. In this case, the `aspectMask` of the `srcSubresource` or `dstSubresource` that refers to the multi-planar image must be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT`, or `VK_IMAGE_ASPECT_PLANE_2_BIT`. For the purposes of `vkCmdCopyImage`, each plane of a multi-planar image is treated as having the format listed in Compatible formats of planes of multi-planar formats for the plane identified by the `aspectMask` of the corresponding subresource. This applies both to `VkFormat` and to coordinates used in the copy, which correspond to texels in the `plane` rather than how these texels map to coordinates in the image as a whole.

> **Note**
>
> For example, the `VK_IMAGE_ASPECT_PLANE_1_BIT` plane of a `VK_FORMAT_G8_B8R8_2PLANE_420_UNORM` image is compatible with an image of format `VK_FORMAT_R8G8_UNORM` and (less usefully) with the `VK_IMAGE_ASPECT_PLANE_0_BIT` plane of an image of format `VK_FORMAT_G10X6_B10X6_R10X6_3PLANE_420_UNORM_3PACK16`, as each texel is 2 bytes in size.

`vkCmdCopyImage` allows copying between size-compatible compressed and uncompressed internal formats. Formats are size-compatible if the texel block size of the uncompressed format is equal to the texel block size of the compressed format. Such a copy does not perform on-the-fly compression or decompression. When copying from an uncompressed format to a compressed format, each texel of uncompressed data of the source image is copied as a raw value to the corresponding compressed texel block of the destination image. When copying from a compressed format to an uncompressed format, each compressed texel block of the source image is copied as a raw value to the corresponding texel of uncompressed data in the destination image. Thus, for example, it is legal to copy between a 128-bit uncompressed format and a compressed format which has a 128-bit sized compressed texel block representing 4×4 texels (using 8 bits per texel), or between a 64-bit uncompressed format and a compressed format which has a 64-bit sized compressed texel block representing 4×4 texels (using 4 bits per texel).

When copying between compressed and uncompressed formats the `extent` members represent the texel dimensions of the source image and not the destination. When copying from a compressed
image to an uncompressed image the image texel dimensions written to the uncompressed image will be source extent divided by the compressed texel block dimensions. When copying from an uncompressed image to a compressed image the image texel dimensions written to the compressed image will be the source extent multiplied by the compressed texel block dimensions. In both cases the number of bytes read and the number of bytes written will be identical.

Copying to or from block-compressed images is typically done in multiples of the compressed texel block size. For this reason the extent must be a multiple of the compressed texel block dimension. There is one exception to this rule which is required to handle compressed images created with dimensions that are not a multiple of the compressed texel block dimensions: if the srcImage is compressed, then:

- If extent.width is not a multiple of the compressed texel block width, then (extent.width + srcOffset.x) must equal the image subresource width.
- If extent.height is not a multiple of the compressed texel block height, then (extent.height + srcOffset.y) must equal the image subresource height.
- If extent.depth is not a multiple of the compressed texel block depth, then (extent.depth + srcOffset.z) must equal the image subresource depth.

Similarly, if the dstImage is compressed, then:

- If extent.width is not a multiple of the compressed texel block width, then (extent.width + dstOffset.x) must equal the image subresource width.
- If extent.height is not a multiple of the compressed texel block height, then (extent.height + dstOffset.y) must equal the image subresource height.
- If extent.depth is not a multiple of the compressed texel block depth, then (extent.depth + dstOffset.z) must equal the image subresource depth.

This allows the last compressed texel block of the image in each non-multiple dimension to be included as a source or destination of the copy.

“_422” image formats that are not multi-planar are treated as having a 2×1 compressed texel block for the purposes of these rules.

vkCmdCopyImage can be used to copy image data between multisample images, but both images must have the same number of samples.
Valid Usage

• The union of all source regions, and the union of all destination regions, specified by the elements of `pRegions`, **must** not overlap in memory

• The **format features** of `srcImage` **must** contain `VK_FORMAT_FEATURE_TRANSFER_SRC_BIT`

• `srcImage` **must** have been created with `VK_IMAGE_USAGE_TRANSFER_SRC_BIT` usage flag

• If `srcImage` is non-sparse then the image or *disjoint* plane to be copied **must** be bound completely and contiguously to a single `VkDeviceMemory` object

• `srcImageLayout` **must** specify the layout of the image subresources of `srcImage` specified in `pRegions` at the time this command is executed on a `VkDevice`

• `srcImageLayout` **must** be `VK_IMAGE_LAYOUT_TRANSFER_SRC_OPTIMAL`, `VK_IMAGE_LAYOUT_GENERAL`, or `VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR`

• The **format features** of `dstImage` **must** contain `VK_FORMAT_FEATURE_TRANSFER_DST_BIT`

• `dstImage` **must** have been created with `VK_IMAGE_USAGE_TRANSFER_DST_BIT` usage flag

• If `dstImage` is non-sparse then the image or *disjoint* plane that is the destination of the copy **must** be bound completely and contiguously to a single `VkDeviceMemory` object

• `dstImageLayout` **must** specify the layout of the image subresources of `dstImage` specified in `pRegions` at the time this command is executed on a `VkDevice`

• `dstImageLayout` **must** be `VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL`, `VK_IMAGE_LAYOUT_GENERAL`, or `VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR`

• If the `VkFormat` of each of `srcImage` and `dstImage` is not a *multi-planar format*, the `VkFormat` of each of `srcImage` and `dstImage` **must** be compatible, as defined above

• In a copy to or from a plane of a *multi-planar image*, the `VkFormat` of the image and plane **must** be compatible according to the description of compatible planes for the plane being copied

• The sample count of `srcImage` and `dstImage` **must** match

• The `srcSubresource.mipLevel` member of each element of `pRegions` **must** be less than the `mipLevels` specified in `VkImageCreateInfo` when `srcImage` was created

• The `dstSubresource.mipLevel` member of each element of `pRegions` **must** be less than the `mipLevels` specified in `VkImageCreateInfo` when `dstImage` was created

• The `srcSubresource.baseArrayLayer + srcSubresource.layerCount` of each element of `pRegions` **must** be less than or equal to the `arrayLayers` specified in `VkImageCreateInfo` when `srcImage` was created

• The `dstSubresource.baseArrayLayer + dstSubresource.layerCount` of each element of `pRegions` **must** be less than or equal to the `arrayLayers` specified in `VkImageCreateInfo` when `dstImage` was created

• The `srcOffset` and `extent` members of each element of `pRegions` **must** respect the image transfer granularity requirements of `commandBuffer`’s command pool’s queue family, as described in `VkQueueFamilyProperties`

• The `dstOffset` and `extent` members of each element of `pRegions` **must** respect the image
transfer granularity requirements of commandBuffer’s command pool's queue family, as described in VkQueueFamilyProperties

- dstImage and srcImage must not have been created with flags containing VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT

Valid Usage (Implicit)

- commandBuffer must be a valid VkCommandBuffer handle
- srcImage must be a valid VkImage handle
- srcImageLayout must be a valid VkImageLayout value
- dstImage must be a valid VkImage handle
- dstImageLayout must be a valid VkImageLayout value
- pRegions must be a valid pointer to an array of regionCount valid VkImageCopy structures
- commandBuffer must be in the recording state
- The VkCommandPool that commandBuffer was allocated from must support transfer, graphics, or compute operations
- This command must only be called outside of a render pass instance
- regionCount must be greater than 0
- Each of commandBuffer, dstImage, and srcImage must have been created, allocated, or retrieved from the same VkDevice

Host Synchronization

- Host access to commandBuffer must be externally synchronized
- Host access to the VkCommandPool that commandBuffer was allocated from must be externally synchronized

Command Properties

<table>

The VkImageCopy structure is defined as:
typedef struct VkImageCopy {
    VkImageSubresourceLayers srcSubresource;
    VkOffset3D srcOffset;
    VkImageSubresourceLayers dstSubresource;
    VkOffset3D dstOffset;
    VkExtent3D extent;
} VkImageCopy;

- `srcSubresource` and `dstSubresource` are `VkImageSubresourceLayers` structures specifying the image subresources of the images used for the source and destination image data, respectively.
- `srcOffset` and `dstOffset` select the initial `x`, `y`, and `z` offsets in texels of the sub-regions of the source and destination image data.
- `extent` is the size in texels of the image to copy in `width`, `height` and `depth`.

For `VK_IMAGE_TYPE_3D` images, copies are performed slice by slice starting with the `z` member of the `srcOffset` or `dstOffset`, and copying `depth` slices. For images with multiple layers, copies are performed layer by layer starting with the `baseArrayLayer` member of the `srcSubresource` or `dstSubresource` and copying `layerCount` layers. Image data can be copied between images with different image types. If one image is `VK_IMAGE_TYPE_3D` and the other image is `VK_IMAGE_TYPE_2D` with multiple layers, then each slice is copied to or from a different layer.

Copies involving a multi-planar image format specify the region to be copied in terms of the `plane` to be copied, not the coordinates of the multi-planar image. This means that copies accessing the R/B planes of “_422” format images must fit the copied region within half the `width` of the parent image, and that copies accessing the R/B planes of “_420” format images must fit the copied region within half the `width` and `height` of the parent image.
Valid Usage

• If neither the calling command’s `srcImage` nor the calling command’s `dstImage` has a multi-planar image format then the `aspectMask` member of `srcSubresource` and `dstSubresource` must match.

• If the calling command’s `srcImage` has a `VkFormat` with two planes then the `srcSubresource` `aspectMask` must be `VK_IMAGE_ASPECT_PLANE_0_BIT` or `VK_IMAGE_ASPECT_PLANE_1_BIT`.

• If the calling command’s `srcImage` has a `VkFormat` with three planes then the `srcSubresource` `aspectMask` must be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT`, or `VK_IMAGE_ASPECT_PLANE_2_BIT`.

• If the calling command’s `dstImage` has a `VkFormat` with two planes then the `dstSubresource` `aspectMask` must be `VK_IMAGE_ASPECT_PLANE_0_BIT` or `VK_IMAGE_ASPECT_PLANE_1_BIT`.

• If the calling command’s `dstImage` has a `VkFormat` with three planes then the `dstSubresource` `aspectMask` must be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT`, or `VK_IMAGE_ASPECT_PLANE_2_BIT`.

• If the calling command’s `srcImage` has a multi-planar image format and the `dstImage` does not have a multi-planar image format, the `dstSubresource` `aspectMask` must be `VK_IMAGE_ASPECT_COLOR_BIT`.

• If the calling command’s `dstImage` has a multi-planar image format and the `srcImage` does not have a multi-planar image format, the `srcSubresource` `aspectMask` must be `VK_IMAGE_ASPECT_COLOR_BIT`.

• The number of slices of the `extent` (for 3D) or layers of the `srcSubresource` (for non-3D) must match the number of slices of the `extent` (for 3D) or layers of the `dstSubresource` (for non-3D).

• If either of the calling command’s `srcImage` or `dstImage` parameters are of `VkImageType VK_IMAGE_TYPE_3D`, the `baseArrayLayer` and `layerCount` members of the corresponding subresource must be 0 and 1, respectively.

• The `aspectMask` member of `srcSubresource` must specify aspects present in the calling command’s `srcImage`.

• The `aspectMask` member of `dstSubresource` must specify aspects present in the calling command’s `dstImage`.

• `srcOffset.x` and `(extent.width + srcOffset.x)` must both be greater than or equal to 0 and less than or equal to the source image subresource width.

• `srcOffset.y` and `(extent.height + srcOffset.y)` must both be greater than or equal to 0 and less than or equal to the source image subresource height.

• If the calling command’s `srcImage` is of type `VK_IMAGE_TYPE_1D`, then `srcOffset.y` must be 0 and `extent.height` must be 1.

• `srcOffset.z` and `(extent.depth + srcOffset.z)` must both be greater than or equal to 0 and less than or equal to the source image subresource depth.

• If the calling command’s `srcImage` is of type `VK_IMAGE_TYPE_1D`, then `srcOffset.z` must be 0.
and $extent\text{.depth}$ must be 1

- If the calling command’s $dstImage$ is of type VK_IMAGE_TYPE_1D, then $dstOffset.z$ must be 0 and $extent\text{.depth}$ must be 1

- If the calling command’s $srcImage$ is of type VK_IMAGE_TYPE_2D, then $srcOffset.z$ must be 0

- If the calling command’s $dstImage$ is of type VK_IMAGE_TYPE_2D, then $dstOffset.z$ must be 0

- If both $srcImage$ and $dstImage$ are of type VK_IMAGE_TYPE_2D then $extent\text{.depth}$ must be 1

- If the calling command’s $srcImage$ is of type VK_IMAGE_TYPE_2D, and the $dstImage$ is of type VK_IMAGE_TYPE_3D, then $extent\text{.depth}$ must equal to the layerCount member of $srcSubresource$

- If the calling command’s $dstImage$ is of type VK_IMAGE_TYPE_2D, and the $srcImage$ is of type VK_IMAGE_TYPE_3D, then $extent\text{.depth}$ must equal to the layerCount member of $dstSubresource$

- $dstOffset.x$ and $(extent\text{.width} + dstOffset.x)$ must both be greater than or equal to 0 and less than or equal to the destination image subresource width

- $dstOffset.y$ and $(extent\text{.height} + dstOffset.y)$ must both be greater than or equal to 0 and less than or equal to the destination image subresource height

- If the calling command’s $dstImage$ is of type VK_IMAGE_TYPE_1D, then $dstOffset.y$ must be 0 and $extent\text{.height}$ must be 1

- $dstOffset.z$ and $(extent\text{.depth} + dstOffset.z)$ must both be greater than or equal to 0 and less than or equal to the destination image subresource depth

- If the calling command’s $srcImage$ is a compressed image, or a single-plane, “.422” image format, all members of $srcOffset$ must be a multiple of the corresponding dimensions of the compressed texel block

- If the calling command’s $srcImage$ is a compressed image, or a single-plane, “.422” image format, $extent\text{.width}$ must be a multiple of the compressed texel block width or $(extent\text{.width} + srcOffset.x)$ must equal the source image subresource width

- If the calling command’s $srcImage$ is a compressed image, or a single-plane, “.422” image format, $extent\text{.height}$ must be a multiple of the compressed texel block height or $(extent\text{.height} + srcOffset.y)$ must equal the source image subresource height

- If the calling command’s $srcImage$ is a compressed image, or a single-plane, “.422” image format, $extent\text{.depth}$ must be a multiple of the compressed texel block depth or $(extent\text{.depth} + srcOffset.z)$ must equal the source image subresource depth

- If the calling command’s $dstImage$ is a compressed format image, or a single-plane, “.422” image format, all members of $dstOffset$ must be a multiple of the corresponding dimensions of the compressed texel block

- If the calling command’s $dstImage$ is a compressed format image, or a single-plane, “.422” image format, $extent\text{.width}$ must be a multiple of the compressed texel block width or $(extent\text{.width} + dstOffset.x)$ must equal the destination image subresource width

- If the calling command’s $dstImage$ is a compressed format image, or a single-plane, “.422” image format, $extent\text{.height}$ must be a multiple of the compressed texel block height or $(extent\text{.height} + dstOffset.y)$ must equal the destination image subresource height
• If the calling command's `dstImage` is a compressed format image, or a single-plane, “.422” image format, `extent.depth` must be a multiple of the compressed texel block depth or `(extent.depth + dstOffset.z)` must equal the destination image subresource depth.

---

**Valid Usage (Implicit)**

• `srcSubresource` must be a valid `VkImageSubresourceLayers` structure
• `dstSubresource` must be a valid `VkImageSubresourceLayers` structure

The `VkImageSubresourceLayers` structure is defined as:

```c
typedef struct VkImageSubresourceLayers {
    VkImageAspectFlags    aspectMask;
    uint32_t              mipLevel;
    uint32_t              baseArrayLayer;
    uint32_t              layerCount;
} VkImageSubresourceLayers;
```

• `aspectMask` is a combination of `VkImageAspectFlagBits`, selecting the color, depth and/or stencil aspects to be copied.
• `mipLevel` is the mipmap level to copy from.
• `baseArrayLayer` and `layerCount` are the starting layer and number of layers to copy.

---

**Valid Usage**

• If `aspectMask` contains `VK_IMAGE_ASPECT_COLOR_BIT`, it must not contain either of `VK_IMAGE_ASPECT_DEPTH_BIT` or `VK_IMAGE_ASPECT_STENCIL_BIT`
• `aspectMask` must not contain `VK_IMAGE_ASPECT_METADATA_BIT`
• `aspectMask` must not include `VK_IMAGE_ASPECT_MEMORY_PLANE_i_BIT_EXT` for any index `i`
• `layerCount` must be greater than 0

---

**Valid Usage (Implicit)**

• `aspectMask` must be a valid combination of `VkImageAspectFlagBits` values
• `aspectMask` must not be 0

---

**19.4. Copying Data Between Buffers and Images**

To copy data from a buffer object to an image object, call:
```c
void vkCmdCopyBufferToImage(
    VkCommandBuffer                             commandBuffer,  // commandBuffer is the command buffer into which the command will be recorded.
    VkBuffer                                    srcBuffer,       // srcBuffer is the source buffer.
    VkImage                                     dstImage,        // dstImage is the destination image.
    VkImageLayout                               dstImageLayout,  // dstImageLayout is the layout of the destination image subresources for the copy.
    uint32_t                                    regionCount,     // regionCount is the number of regions to copy.
    const VkBufferImageCopy*                    pRegions);       // pRegions is a pointer to an array of VkBufferImageCopy structures specifying the regions to copy.
```

Each region in `pRegions` is copied from the specified region of the source buffer to the specified region of the destination image.

If the format of `dstImage` is a **multi-planar image format**), regions of each plane to be a target of a copy **must** be specified separately using the `pRegions` member of the `VkBufferImageCopy` structure. In this case, the `aspectMask` of `imageSubresource` **must** be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT`, or `VK_IMAGE_ASPECT_PLANE_2_BIT`. For the purposes of `vkCmdCopyBufferToImage`, each plane of a multi-planar image is treated as having the format listed in **Compatible formats of planes of multi-planar formats** for the plane identified by the `aspectMask` of the corresponding subresource. This applies both to `VkFormat` and to coordinates used in the copy, which correspond to texels in the **plane** rather than how these texels map to coordinates in the image as a whole.
Valid Usage

- **srcBuffer** must be large enough to contain all buffer locations that are accessed according to Buffer and Image Addressing, for each element of **pRegions**

- The image region specified by each element of **pRegions** must be a region that is contained within **dstImage** if the **dstImage**’s **VkFormat** is not a multi-planar format, and must be a region that is contained within the plane being copied to if the **dstImage**’s **VkFormat** is a multi-planar format

- The union of all source regions, and the union of all destination regions, specified by the elements of **pRegions**, must not overlap in memory

- **srcBuffer** must have been created with **VK_BUFFER_USAGE_TRANSFER_SRC_BIT** usage flag

- The format features of **dstImage** must contain **VK_FORMAT_FEATURE_TRANSFER_DST_BIT**

- If **srcBuffer** is non-sparse then it must be bound completely and contiguously to a single **VkDeviceMemory** object

- **dstImage** must have been created with **VK_IMAGE_USAGE_TRANSFER_DST_BIT** usage flag

- If **dstImage** is non-sparse then it must be bound completely and contiguously to a single **VkDeviceMemory** object

- **dstImage** must have a sample count equal to **VK_SAMPLE_COUNT_1_BIT**

- **dstImageLayout** must specify the layout of the image subresources of **dstImage** specified in **pRegions** at the time this command is executed on a **VkDevice**

- **dstImageLayout** must be **VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL**, **VK_IMAGE_LAYOUT_GENERAL**, or **VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR**

- The imageSubresource.mipLevel member of each element of **pRegions** must be less than the mipLevels specified in **VkImageCreateInfo** when **dstImage** was created

- The imageSubresource.baseArrayLayer + imageSubresource.layerCount of each element of **pRegions** must be less than or equal to the arrayLayers specified in **VkImageCreateInfo** when **dstImage** was created

- The imageOffset and imageExtent members of each element of **pRegions** must respect the image transfer granularity requirements of commandBuffer’s command pool’s queue family, as described in **VkQueueFamilyProperties**

- **dstImage** must not have been created with flags containing **VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT**
Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `srcBuffer` must be a valid `VkBuffer` handle
- `dstImage` must be a valid `VkImage` handle
- `dstImageLayout` must be a valid `VkImageLayout` value
- `pRegions` must be a valid pointer to an array of `regionCount` valid `VkBufferImageCopy` structures
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support transfer, graphics, or compute operations
- This command must only be called outside of a render pass instance
- `regionCount` must be greater than 0
- Each of `commandBuffer`, `dstImage`, and `srcBuffer` must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>

<td>Compute</td>
<td></td>
</tr>
</tbody>
</table>

To copy data from an image object to a buffer object, call:

```c
void vkCmdCopyImageToBuffer(
    VkCommandBuffer commandBuffer,
    VkImage srcImage,
    VkImageLayout srcImageLayout,
    VkBuffer dstBuffer,
    uint32_t regionCount,
    const VkBufferImageCopy* pRegions);
```
• `commandBuffer` is the command buffer into which the command will be recorded.
• `srcImage` is the source image.
• `srcImageLayout` is the layout of the source image subresources for the copy.
• `dstBuffer` is the destination buffer.
• `regionCount` is the number of regions to copy.
• `pRegions` is a pointer to an array of `VkBufferImageCopy` structures specifying the regions to copy.

Each region in `pRegions` is copied from the specified region of the source image to the specified region of the destination buffer.

If the `VkFormat` of `srcImage` is a multi-planar image format, regions of each plane to be a source of a copy **must** be specified separately using the `pRegions` member of the `VkBufferImageCopy` structure. In this case, the `aspectMask` of `imageSubresource` **must** be `VK_IMAGE_ASPECT_PLANE_0_BIT`, `VK_IMAGE_ASPECT_PLANE_1_BIT`, or `VK_IMAGE_ASPECT_PLANE_2_BIT`. For the purposes of `vkCmdCopyBufferToImage`, each plane of a multi-planar image is treated as having the format listed in Compatible formats of planes of multi-planar formats for the plane identified by the `aspectMask` of the corresponding subresource. This applies both to `VkFormat` and to coordinates used in the copy, which correspond to texels in the plane rather than how these texels map to coordinates in the image as a whole.
Valid Usage

- The image region specified by each element of `pRegions` must be a region that is contained within `srcImage` if the `srcImage`'s `VkFormat` is not a multi-planar format, and must be a region that is contained within the plane being copied if the `srcImage`'s `VkFormat` is a multi-planar format.

- `dstBuffer` must be large enough to contain all buffer locations that are accessed according to Buffer and Image Addressing, for each element of `pRegions`.

- The union of all source regions, and the union of all destination regions, specified by the elements of `pRegions`, must not overlap in memory.

- The format features of `srcImage` must contain `VK_FORMAT_FEATURE_TRANSFER_SRC_BIT`.

- `srcImage` must have been created with `VK_IMAGE_USAGE_TRANSFER_SRC_BIT` usage flag.

- If `srcImage` is non-sparse then it must be bound completely and contiguously to a single `VkDeviceMemory` object.

- `srcImage` must have a sample count equal to `VK_SAMPLE_COUNT_1_BIT`.

- `srcImageLayout` must specify the layout of the image subresources of `srcImage` specified in `pRegions` at the time this command is executed on a `VkDevice`.

- `srcImageLayout` must be `VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR`, `VK_IMAGE_LAYOUT_TRANSFER_SRC_OPTIMAL` or `VK_IMAGE_LAYOUT_GENERAL`.

- `dstBuffer` must have been created with `VK_BUFFER_USAGE_TRANSFER_DST_BIT` usage flag.

- If `dstBuffer` is non-sparse then it must be bound completely and contiguously to a single `VkDeviceMemory` object.

- The `imageSubresource.mipLevel` member of each element of `pRegions` must be less than the `mipLevels` specified in `VkImageCreateInfo` when `srcImage` was created.

- The `imageSubresource.baseArrayLayer + imageSubresource.layerCount` of each element of `pRegions` must be less than or equal to the `arrayLayers` specified in `VkImageCreateInfo` when `srcImage` was created.

- The `imageOffset` and `imageExtent` members of each element of `pRegions` must respect the image transfer granularity requirements of `commandBuffer`'s command pool's queue family, as described in `VkQueueFamilyProperties`.

- `srcImage` must not have been created with flags containing `VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT`.
Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `srcImage` must be a valid `VkImage` handle
- `srcImageLayout` must be a valid `VkImageLayout` value
- `dstBuffer` must be a valid `VkBuffer` handle
- `pRegions` must be a valid pointer to an array of `regionCount` valid `VkBufferImageCopy` structures
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support transfer, graphics, or compute operations
- This command must only be called outside of a render pass instance
- `regionCount` must be greater than 0
- Each of `commandBuffer`, `dstBuffer`, and `srcImage` must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Outside</td>
<td>Transfer</td>
<td>Transfer</td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td>Graphics</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Compute</td>
<td></td>
</tr>
</tbody>
</table>

For both `vkCmdCopyBufferToImage` and `vkCmdCopyImageToBuffer`, each element of `pRegions` is a structure defined as:
typedef struct VkBufferImageCopy {
    VkDeviceSize                bufferOffset;
    uint32_t                    bufferRowLength;
    uint32_t                    bufferImageHeight;
    VkImageSubresourceLayers    imageSubresource;
    VkOffset3D                  imageOffset;
    VkExtent3D                  imageExtent;
} VkBufferImageCopy;

- bufferOffset is the offset in bytes from the start of the buffer object where the image data is copied from or to.
- bufferRowLength and bufferImageHeight specify in texels a subregion of a larger two- or three-dimensional image in buffer memory, and control the addressing calculations. If either of these values is zero, that aspect of the buffer memory is considered to be tightly packed according to the imageExtent.
- imageSubresource is a VkImageSubresourceLayers used to specify the specific image subresources of the image used for the source or destination image data.
- imageOffset selects the initial x, y, z offsets in texels of the sub-region of the source or destination image data.
- imageExtent is the size in texels of the image to copy in width, height and depth.

When copying to or from a depth or stencil aspect, the data in buffer memory uses a layout that is a (mostly) tightly packed representation of the depth or stencil data. Specifically:

- data copied to or from the stencil aspect of any depth/stencil format is tightly packed with one VK_FORMAT_S8_UINT value per texel.
- data copied to or from the depth aspect of a VK_FORMAT_D16_UNORM or VK_FORMAT_D16_UNORM_S8_UINT format is tightly packed with one VK_FORMAT_D16_UNORM value per texel.
- data copied to or from the depth aspect of a VK_FORMAT_D32_SFLOAT or VK_FORMAT_D32_SFLOAT_S8_UINT format is tightly packed with one VK_FORMAT_D32_SFLOAT value per texel.
- data copied to or from the depth aspect of a VK_FORMAT_X8_D24_UNORM_PACK32 or VK_FORMAT_D24_UNORM_S8_UINT format is packed with one 32-bit word per texel with the D24 value in the LSBs of the word, and undefined values in the eight MSBs.

Note

To copy both the depth and stencil aspects of a depth/stencil format, two entries in pRegions can be used, where one specifies the depth aspect in imageSubresource, and the other specifies the stencil aspect.

Because depth or stencil aspect buffer to image copies may require format conversions on some implementations, they are not supported on queues that do not support graphics.

When copying to a depth aspect, and the VK_EXT_depth_range_unrestricted extension is not enabled, the data in buffer memory must be in the range [0,1], or the resulting values are undefined.
Copies are done layer by layer starting with image layer baseArrayLayer member of imageSubresource. layerCount layers are copied from the source image or to the destination image.
Valid Usage

• If the calling command’s VkImage parameter’s format is not a depth/stencil format or a multi-planar format, then bufferOffset must be a multiple of the format’s texel block size.

• If the calling command’s VkImage parameter’s format is a multi-planar format, then bufferOffset must be a multiple of the element size of the compatible format for the format and the aspectMask of the imageSubresource as defined in Compatible formats of planes of multi-planar formats.

• bufferOffset must be a multiple of 4.

• bufferRowLength must be 0, or greater than or equal to the width member of imageExtent.

• bufferOffsetHeight must be 0, or greater than or equal to the height member of imageExtent.

• imageOffset.x and (imageExtent.width + imageOffset.x) must both be greater than or equal to 0 and less than or equal to the image subresource width where this refers to the width of the plane of the image involved in the copy in the case of a multi-planar format.

• imageOffset.y and (imageExtent.height + imageOffset.y) must both be greater than or equal to 0 and less than or equal to the image subresource height where this refers to the height of the plane of the image involved in the copy in the case of a multi-planar format.

• If the calling command’s srcImage (vkCmdCopyImageToBuffer) or dstImage (vkCmdCopyBufferToImage) is of type VK_IMAGE_TYPE_1D, then imageOffset.y must be 0 and imageExtent.height must be 1.

• imageOffset.z and (imageExtent.depth + imageOffset.z) must both be greater than or equal to 0 and less than or equal to the image subresource depth.

• If the calling command’s srcImage (vkCmdCopyImageToBuffer) or dstImage (vkCmdCopyBufferToImage) is of type VK_IMAGE_TYPE_1D or VK_IMAGE_TYPE_2D, then imageOffset.z must be 0 and imageExtent.depth must be 1.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, bufferRowLength must be a multiple of the compressed texel block width.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, bufferImageHeight must be a multiple of the compressed texel block height.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, all members of imageOffset must be a multiple of the corresponding dimensions of the compressed texel block.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, bufferOffset must be a multiple of the compressed texel block size in bytes.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, imageExtent.width must be a multiple of the compressed texel block width or (imageExtent.width + imageOffset.x) must equal the image subresource width.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, imageExtent.height must be a multiple of the compressed texel block height.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, all members of imageOffset must be a multiple of the corresponding dimensions of the compressed texel block.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, bufferOffset must be a multiple of the compressed texel block size in bytes.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, imageExtent.width must be a multiple of the compressed texel block width or (imageExtent.width + imageOffset.x) must equal the image subresource width.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, imageExtent.height must be a multiple of the compressed texel block height.

• If the calling command’s VkImage parameter is a compressed image, or a single-plane, “_422” image format, all members of imageOffset must be a multiple of the corresponding dimensions of the compressed texel block.
image format, \texttt{imageExtent.height} must be a multiple of the compressed texel block height or \((\texttt{imageExtent.height} + \texttt{imageOffset.y})\) must equal the image subresource height.

- If the calling command’s \texttt{VkImage} parameter is a compressed image, or a \textit{single-plane}, “\_422” image format, \texttt{imageExtent.depth} must be a multiple of the compressed texel block depth or \((\texttt{imageExtent.depth} + \texttt{imageOffset.z})\) must equal the image subresource depth.

- The \texttt{aspectMask} member of \texttt{imageSubresource} must specify aspects present in the calling command’s \texttt{VkImage} parameter.

- If the calling command’s \texttt{VkImage} parameter’s format is a \textit{multi-planar format}, then the \texttt{aspectMask} member of \texttt{imageSubresource} must be \texttt{VK_IMAGE_ASPECT_PLANE_0_BIT}, \texttt{VK_IMAGE_ASPECT_PLANE_1_BIT}, or \texttt{VK_IMAGE_ASPECT_PLANE_2_BIT} (with \texttt{VK_IMAGE_ASPECT_PLANE_2_BIT} valid only for image formats with three planes).

- The \texttt{aspectMask} member of \texttt{imageSubresource} must only have a single bit set.

- If the calling command’s \texttt{VkImage} parameter is of \texttt{VkImageType VK_IMAGE_TYPE_3D}, the \texttt{baseArrayLayer} and \texttt{layerCount} members of \texttt{imageSubresource} must be \texttt{0} and \texttt{1}, respectively.

### Valid Usage (Implicit)

- \texttt{imageSubresource} must be a valid \texttt{VkImageSubresourceLayers} structure.

### 19.4.1. Buffer and Image Addressing

Pseudocode for image/buffer addressing of uncompressed formats is:

```plaintext
rowLength = region->bufferRowLength;
if (rowLength == 0)
    rowLength = region->imageExtent.width;

imageHeight = region->bufferImageHeight;
if (imageHeight == 0)
    imageHeight = region->imageExtent.height;

texelBlockSize = \langle\text{texel block size of the format of the src/dstImage}\rangle;

address of (x,y,z) = region->bufferOffset + (((z * imageHeight) + y) * rowLength + x) * texelBlockSize;

where x,y,z range from \((0,0,0)\) to region->imageExtent.{width,height,depth}.
```

Note that \texttt{imageOffset} does not affect addressing calculations for buffer memory. Instead, \texttt{bufferOffset} can be used to select the starting address in buffer memory.

For block-compressed formats, all parameters are still specified in texels rather than compressed texel blocks, but the addressing math operates on whole compressed texel blocks. Pseudocode for compressed copy addressing is:
rowLength = region->bufferRowLength;
if (rowLength == 0)
    rowLength = region->imageExtent.width;

imageHeight = region->bufferImageHeight;
if (imageHeight == 0)
    imageHeight = region->imageExtent.height;

compressedTexelBlockSizeInBytes = <compressed texel block size taken from the src/dstImage>;
rowLength /= compressedTexelBlockWidth;
imageHeight /= compressedTexelBlockHeight;

address of (x,y,z) = region->bufferOffset + (((z * imageHeight) + y) * rowLength + x) * compressedTexelBlockSizeInBytes;

where x,y,z range from (0,0,0) to region->imageExtent.{width/compressedTexelBlockWidth,height/compressedTexelBlockHeight,depth/compressedTexelBlockDepth}.

Copying to or from block-compressed images is typically done in multiples of the compressed texel block size. For this reason the imageExtent must be a multiple of the compressed texel block dimension. There is one exception to this rule which is required to handle compressed images created with dimensions that are not a multiple of the compressed texel block dimensions:

- If imageExtent.width is not a multiple of the compressed texel block width, then (imageExtent.width + imageOffset.x) must equal the image subresource width.
- If imageExtent.height is not a multiple of the compressed texel block height, then (imageExtent.height + imageOffset.y) must equal the image subresource height.
- If imageExtent.depth is not a multiple of the compressed texel block depth, then (imageExtent.depth + imageOffset.z) must equal the image subresource depth.

This allows the last compressed texel block of the image in each non-multiple dimension to be included as a source or destination of the copy.

19.5. Image Copies with Scaling

To copy regions of a source image into a destination image, potentially performing format conversion, arbitrary scaling, and filtering, call:
void vkCmdBlitImage(
    VkCommandBuffer                             commandBuffer,
    VkImage                                     srcImage,
    VkImageLayout                               srcImageLayout,
    VkImage                                     dstImage,
    VkImageLayout                               dstImageLayout,
    uint32_t                                    regionCount,
    const VkImageBlit*                          pRegions,
    VkFilter                                    filter);

- **commandBuffer** is the command buffer into which the command will be recorded.
- **srcImage** is the source image.
- **srcImageLayout** is the layout of the source image subresources for the blit.
- **dstImage** is the destination image.
- **dstImageLayout** is the layout of the destination image subresources for the blit.
- **regionCount** is the number of regions to blit.
- **pRegions** is a pointer to an array of VkImageBlit structures specifying the regions to blit.
- **filter** is a VkFilter specifying the filter to apply if the blits require scaling.

vkCmdBlitImage **must** not be used for multisampled source or destination images. Use vkCmdResolveImage for this purpose.

As the sizes of the source and destination extents **can** differ in any dimension, texels in the source extent are scaled and filtered to the destination extent. Scaling occurs via the following operations:

- For each destination texel, the integer coordinate of that texel is converted to an unnormalized texture coordinate, using the effective inverse of the equations described in **unnormalized to integer conversion**:

  \[ u_{\text{base}} = i + \frac{1}{2} \]

  \[ v_{\text{base}} = j + \frac{1}{2} \]

  \[ w_{\text{base}} = k + \frac{1}{2} \]

- These base coordinates are then offset by the first destination offset:

  \[ u_{\text{offset}} = u_{\text{base}} - x_{\text{dst0}} \]

  \[ v_{\text{offset}} = v_{\text{base}} - y_{\text{dst0}} \]
\[ w_{\text{offset}} = w_{\text{base}} - z_{\text{dst}} \]

\[ a_{\text{offset}} = a - \text{baseArrayCount}_{\text{dst}} \]

- The scale is determined from the source and destination regions, and applied to the offset coordinates:

\[ \text{scale}_u = \frac{x_{\text{src}1} - x_{\text{src}0}}{x_{\text{dst}1} - x_{\text{dst}0}} \]

\[ \text{scale}_v = \frac{y_{\text{src}1} - y_{\text{src}0}}{y_{\text{dst}1} - y_{\text{dst}0}} \]

\[ \text{scale}_w = \frac{z_{\text{src}1} - z_{\text{src}0}}{z_{\text{dst}1} - z_{\text{dst}0}} \]

\[ u_{\text{scaled}} = u_{\text{offset}} \times \text{scale}_u \]

\[ v_{\text{scaled}} = v_{\text{offset}} \times \text{scale}_v \]

\[ w_{\text{scaled}} = w_{\text{offset}} \times \text{scale}_w \]

- Finally the source offset is added to the scaled coordinates, to determine the final unnormalized coordinates used to sample from \textit{srcImage}:

\[ u = u_{\text{scaled}} + x_{\text{src}0} \]

\[ v = v_{\text{scaled}} + y_{\text{src}0} \]

\[ w = w_{\text{scaled}} + z_{\text{src}0} \]

\[ q = \text{mipLevel} \]

\[ a = a_{\text{offset}} + \text{baseArrayCount}_{\text{src}} \]

These coordinates are used to sample from the source image, as described in \textit{Image Operations} chapter, with the filter mode equal to that of \textit{filter}, a mipmap mode of \textit{VK_SAMPLER_MIPMAP_MODE_NEAREST} and an address mode of \textit{VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE}. 
Implementations **must** clamp at the edge of the source image, and **may** additionally clamp to the edge of the source region.

**Note**

Due to allowable rounding errors in the generation of the source texture coordinates, it is not always possible to guarantee exactly which source texels will be sampled for a given blit. As rounding errors are implementation dependent, the exact results of a blitting operation are also implementation dependent.

Blits are done layer by layer starting with the `baseArrayLayer` member of `srcSubresource` for the source and `dstSubresource` for the destination. `layerCount` layers are blitted to the destination image.

3D textures are blitted slice by slice. Slices in the source region bounded by `srcOffsets[0].z` and `srcOffsets[1].z` are copied to slices in the destination region bounded by `dstOffsets[0].z` and `dstOffsets[1].z`. For each destination slice, a source z coordinate is linearly interpolated between `srcOffsets[0].z` and `srcOffsets[1].z`. If the `filter` parameter is `VK_FILTER_LINEAR` then the value sampled from the source image is taken by doing linear filtering using the interpolated z coordinate. If `filter` parameter is `VK_FILTER_NEAREST` then the value sampled from the source image is taken from the single nearest slice, with an implementation-dependent arithmetic rounding mode.

The following filtering and conversion rules apply:

- Integer formats **can** only be converted to other integer formats with the same signedness.
- No format conversion is supported between depth/stencil images. The formats **must** match.
- Format conversions on unorm, snorm, unscaled and packed float formats of the copied aspect of the image are performed by first converting the pixels to float values.
- For sRGB source formats, nonlinear RGB values are converted to linear representation prior to filtering.
- After filtering, the float values are first clamped and then cast to the destination image format. In case of sRGB destination format, linear RGB values are converted to nonlinear representation before writing the pixel to the image.

Signed and unsigned integers are converted by first clamping to the representable range of the destination format, then casting the value.
Valid Usage

- The source region specified by each element of \( p\text{Regions} \) must be a region that is contained within \( \text{srcImage} \).
- The destination region specified by each element of \( p\text{Regions} \) must be a region that is contained within \( \text{dstImage} \).
- The union of all destination regions, specified by the elements of \( p\text{Regions} \), must not overlap in memory with any texel that may be sampled during the blit operation.
- The format features of \( \text{srcImage} \) must contain \( \text{VK_FORMAT_FEATURE_BLIT_SRC_BIT} \).
- \( \text{srcImage} \) must not use a format listed in Formats requiring sampler \( \text{Y}'C_bC_r \) conversion for \( \text{VK_IMAGE_ASPECT_COLOR_BIT} \) image views.
- \( \text{srcImage} \) must have been created with \( \text{VK_IMAGE_USAGE_TRANSFER_SRC_BIT} \) usage flag.
- If \( \text{srcImage} \) is non-sparse then it must be bound completely and contiguously to a single \( \text{VkDeviceMemory} \) object.
- \( \text{srcImageLayout} \) must specify the layout of the image subresources of \( \text{srcImage} \) specified in \( p\text{Regions} \) at the time this command is executed on a \( \text{VkDevice} \).
- \( \text{srcImageLayout} \) must be \( \text{VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR} \), \( \text{VK_IMAGE_LAYOUT_TRANSFER_SRC_OPTIMAL} \) or \( \text{VK_IMAGE_LAYOUT_GENERAL} \).
- The format features of \( \text{dstImage} \) must contain \( \text{VK_FORMAT_FEATURE_BLIT_DST_BIT} \).
- \( \text{dstImage} \) must not use a format listed in Formats requiring sampler \( \text{Y}'C_bC_r \) conversion for \( \text{VK_IMAGE_ASPECT_COLOR_BIT} \) image views.
- \( \text{dstImage} \) must have been created with \( \text{VK_IMAGE_USAGE_TRANSFER_DST_BIT} \) usage flag.
- If \( \text{dstImage} \) is non-sparse then it must be bound completely and contiguously to a single \( \text{VkDeviceMemory} \) object.
- \( \text{dstImageLayout} \) must specify the layout of the image subresources of \( \text{dstImage} \) specified in \( p\text{Regions} \) at the time this command is executed on a \( \text{VkDevice} \).
- \( \text{dstImageLayout} \) must be \( \text{VK_IMAGE_LAYOUT_SHARED_PRESENT_KHR} \), \( \text{VK_IMAGE_LAYOUT_TRANSFER_DST_OPTIMAL} \) or \( \text{VK_IMAGE_LAYOUT_GENERAL} \).
- If either of \( \text{srcImage} \) or \( \text{dstImage} \) was created with a signed integer \( \text{VkFormat} \), the other must also have been created with a signed integer \( \text{VkFormat} \).
- If either of \( \text{srcImage} \) or \( \text{dstImage} \) was created with an unsigned integer \( \text{VkFormat} \), the other must also have been created with an unsigned integer \( \text{VkFormat} \).
- If either of \( \text{srcImage} \) or \( \text{dstImage} \) was created with a depth/stencil format, the other must have exactly the same format.
- If \( \text{srcImage} \) was created with a depth/stencil format, \( \text{filter} \) must be \( \text{VK_FILTER_NEAREST} \).
- \( \text{srcImage} \) must have been created with a \( \text{samples} \) value of \( \text{VK_SAMPLE_COUNT_1_BIT} \).
- \( \text{dstImage} \) must have been created with a \( \text{samples} \) value of \( \text{VK_SAMPLE_COUNT_1_BIT} \).
- If \( \text{filter} \) is \( \text{VK_FILTER_LINEAR} \), then the format features of \( \text{srcImage} \) must contain \( \text{VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_LINEAR_BIT} \).
• If `filter` is `VK_FILTER_CUBIC_EXT`, then the `format features` of `srcImage` must contain `VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_CUBIC_BIT_EXT`

• If `filter` is `VK_FILTER_CUBIC_EXT`, `srcImage` must have a `VkImageType` of `VK_IMAGE_TYPE_2D`

• The `srcSubresource.mipLevel` member of each element of `pRegions` must be less than the `mipLevels` specified in `VkImageCreateInfo` when `srcImage` was created

• The `dstSubresource.mipLevel` member of each element of `pRegions` must be less than the `mipLevels` specified in `VkImageCreateInfo` when `dstImage` was created

• The `srcSubresource.baseArrayLayer + srcSubresource.layerCount` of each element of `pRegions` must be less than or equal to the `arrayLayers` specified in `VkImageCreateInfo` when `srcImage` was created

• The `dstSubresource.baseArrayLayer + dstSubresource.layerCount` of each element of `pRegions` must be less than or equal to the `arrayLayers` specified in `VkImageCreateInfo` when `dstImage` was created

• `dstImage` and `srcImage` must not have been created with `flags` containing `VK_IMAGE_CREATE_SUBSAMPLED_BIT_EXT`

---

**Valid Usage (Implicit)**

• `commandBuffer` must be a valid `VkCommandBuffer` handle

• `srcImage` must be a valid `VkImage` handle

• `srcImageLayout` must be a valid ` VkImageLayout` value

• `dstImage` must be a valid `VkImage` handle

• `dstImageLayout` must be a valid `VkImageLayout` value

• `pRegions` must be a valid pointer to an array of `regionCount` valid `VkImageBlit` structures

• `filter` must be a valid `VkFilter` value

• `commandBuffer` must be in the recording state

• The `VkCommandPool` that `commandBuffer` was allocated from must support graphics operations

• This command must only be called outside of a render pass instance

• `regionCount` must be greater than 0

• Each of `commandBuffer`, `dstImage`, and `srcImage` must have been created, allocated, or retrieved from the same `VkDevice`

---

**Host Synchronization**

• Host access to `commandBuffer` must be externally synchronized

• Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized
Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>

The `VkImageBlit` structure is defined as:

```c
typedef struct VkImageBlit {
    VkImageSubresourceLayers srcSubresource;
    VkOffset3D srcOffsets[2];
    VkImageSubresourceLayers dstSubresource;
    VkOffset3D dstOffsets[2];
} VkImageBlit;
```

- `srcSubresource` is the subresource to blit from.
- `srcOffsets` is a pointer to an array of two `VkOffset3D` structures specifying the bounds of the source region within `srcSubresource`.
- `dstSubresource` is the subresource to blit into.
- `dstOffsets` is a pointer to an array of two `VkOffset3D` structures specifying the bounds of the destination region within `dstSubresource`.

For each element of the `pRegions` array, a blit operation is performed the specified source and destination regions.
Valid Usage

• The `aspectMask` member of `srcSubresource` and `dstSubresource` **must** match

• The `layerCount` member of `srcSubresource` and `dstSubresource` **must** match

• If either of the calling command’s `srcImage` or `dstImage` parameters are of `VkImageType VK_IMAGE_TYPE_3D`, the `baseArrayLayer` and `layerCount` members of both `srcSubresource` and `dstSubresource` **must** be 0 and 1, respectively

• The `aspectMask` member of `srcSubresource` **must** specify aspects present in the calling command’s `srcImage`

• The `aspectMask` member of `dstSubresource` **must** specify aspects present in the calling command’s `dstImage`

  - `srcOffset[0].x` and `srcOffset[1].x` **must** both be greater than or equal to 0 and less than or equal to the source image subresource width

  - `srcOffset[0].y` and `srcOffset[1].y` **must** both be greater than or equal to 0 and less than or equal to the source image subresource height

  - If the calling command’s `srcImage` is of type `VK_IMAGE_TYPE_1D`, then `srcOffset[0].y` **must** be 0 and `srcOffset[1].y` **must** be 1

  - `srcOffset[0].z` and `srcOffset[1].z` **must** both be greater than or equal to 0 and less than or equal to the source image subresource depth

  - If the calling command’s `srcImage` is of type `VK_IMAGE_TYPE_1D` or `VK_IMAGE_TYPE_2D`, then `srcOffset[0].z` **must** be 0 and `srcOffset[1].z` **must** be 1

  - `dstOffset[0].x` and `dstOffset[1].x` **must** both be greater than or equal to 0 and less than or equal to the destination image subresource width

  - `dstOffset[0].y` and `dstOffset[1].y` **must** both be greater than or equal to 0 and less than or equal to the destination image subresource height

  - If the calling command’s `dstImage` is of type `VK_IMAGE_TYPE_1D`, then `dstOffset[0].y` **must** be 0 and `dstOffset[1].y` **must** be 1

  - `dstOffset[0].z` and `dstOffset[1].z` **must** both be greater than or equal to 0 and less than or equal to the destination image subresource depth

  - If the calling command’s `dstImage` is of type `VK_IMAGE_TYPE_1D` or `VK_IMAGE_TYPE_2D`, then `dstOffset[0].z` **must** be 0 and `dstOffset[1].z` **must** be 1

Valid Usage (Implicit)

• `srcSubresource` **must** be a valid `VkImageSubresourceLayers` structure

• `dstSubresource` **must** be a valid `VkImageSubresourceLayers` structure
19.6. Resolving Multisample Images

To resolve a multisample image to a non-multisample image, call:

```c
void vkCmdResolveImage(
    VkCommandBuffer commandBuffer,
    VkImage srcImage,
    VkImageLayout srcImageLayout,
    VkImage dstImage,
    VkImageLayout dstImageLayout,
    uint32_t regionCount,
    const VkImageResolve* pRegions);
```

- **commandBuffer** is the command buffer into which the command will be recorded.
- **srcImage** is the source image.
- **srcImageLayout** is the layout of the source image subresources for the resolve.
- **dstImage** is the destination image.
- **dstImageLayout** is the layout of the destination image subresources for the resolve.
- **regionCount** is the number of regions to resolve.
- **pRegions** is a pointer to an array of **VkImageResolve** structures specifying the regions to resolve.

During the resolve the samples corresponding to each pixel location in the source are converted to a single sample before being written to the destination. If the source formats are floating-point or normalized types, the sample values for each pixel are resolved in an implementation-dependent manner. If the source formats are integer types, a single sample's value is selected for each pixel.

**srcOffset** and **dstOffset** select the initial x, y, and z offsets in texels of the sub-regions of the source and destination image data. **extent** is the size in texels of the source image to resolve in width, height and depth.

Resolves are done layer by layer starting with **baseArrayLayer** member of **srcSubresource** for the source and **dstSubresource** for the destination. **layerCount** layers are resolved to the destination image.
Valid Usage

- The source region specified by each element of \texttt{pRegions must} be a region that is contained within \texttt{srcImage}
- The destination region specified by each element of \texttt{pRegions must} be a region that is contained within \texttt{dstImage}
- The union of all source regions, and the union of all destination regions, specified by the elements of \texttt{pRegions, must} not overlap in memory
- If \texttt{srcImage} is non-sparse then it \texttt{must} be bound completely and contiguously to a single \texttt{VkDeviceMemory} object
- \texttt{srcImage must} have a sample count equal to any valid sample count value other than \texttt{VK\_SAMPLE\_COUNT\_1\_BIT}
- If \texttt{dstImage} is non-sparse then it \texttt{must} be bound completely and contiguously to a single \texttt{VkDeviceMemory} object
- \texttt{dstImage must} have a sample count equal to \texttt{VK\_SAMPLE\_COUNT\_1\_BIT}
- \texttt{srcImageLayout must} specify the layout of the image subresources of \texttt{srcImage} specified in \texttt{pRegions} at the time this command is executed on a \texttt{VkDevice}
- \texttt{srcImageLayout must} be \texttt{VK\_IMAGE\_LAYOUT\_SHARED\_PRESENT\_KHR, VK\_IMAGE\_LAYOUT\_TRANSFER\_SRC\_OPTIMAL} or \texttt{VK\_IMAGE\_LAYOUT\_GENERAL}
- \texttt{dstImageLayout must} specify the layout of the image subresources of \texttt{dstImage} specified in \texttt{pRegions} at the time this command is executed on a \texttt{VkDevice}
- \texttt{dstImageLayout must} be \texttt{VK\_IMAGE\_LAYOUT\_SHARED\_PRESENT\_KHR, VK\_IMAGE\_LAYOUT\_TRANSFER\_DST\_OPTIMAL} or \texttt{VK\_IMAGE\_LAYOUT\_GENERAL}
- The \texttt{format features} of \texttt{dstImage must} contain \texttt{VK\_FORMAT\_FEATURE\_COLOR\_ATTACHMENT\_BIT}
- \texttt{srcImage} and \texttt{dstImage must} have been created with the same image format
- The \texttt{srcSubresource.mipLevel} member of each element of \texttt{pRegions must} be less than the \texttt{mipLevels} specified in \texttt{VkImageCreateInfo} when \texttt{srcImage} was created
- The \texttt{dstSubresource.mipLevel} member of each element of \texttt{pRegions must} be less than the \texttt{mipLevels} specified in \texttt{VkImageCreateInfo} when \texttt{dstImage} was created
- The \texttt{srcSubresource.baseArrayLayer + srcSubresource.layerCount} of each element of \texttt{pRegions must} be less than or equal to the \texttt{arrayLayers} specified in \texttt{VkImageCreateInfo} when \texttt{srcImage} was created
- The \texttt{dstSubresource.baseArrayLayer + dstSubresource.layerCount} of each element of \texttt{pRegions must} be less than or equal to the \texttt{arrayLayers} specified in \texttt{VkImageCreateInfo} when \texttt{dstImage} was created
- \texttt{dstImage} and \texttt{srcImage must} not have been created with \texttt{flags} containing \texttt{VK\_IMAGE\_CREATE\_SUBSAMPLED\_BIT\_EXT}
Valid Usage (Implicit)

- **commandBuffer** must be a valid `VkCommandBuffer` handle
- **srcImage** must be a valid `VkImage` handle
- **srcImageLayout** must be a valid `VkImageLayout` value
- **dstImage** must be a valid `VkImage` handle
- **dstImageLayout** must be a valid `VkImageLayout` value
- **pRegions** must be a valid pointer to an array of `regionCount` valid `VkImageResolve` structures
- **commandBuffer** must be in the recording state
- The `VkCommandPool` that **commandBuffer** was allocated from must support graphics operations
- This command must only be called outside of a render pass instance
- **regionCount** must be greater than 0
- Each of **commandBuffer**, **dstImage**, and **srcImage** must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to **commandBuffer** must be externally synchronized
- Host access to the `VkCommandPool` that **commandBuffer** was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>

The `VkImageResolve` structure is defined as:

typedef struct VkImageResolve {
    VkImageSubresourceLayers srcSubresource;
    VkOffset3D srcOffset;
    VkImageSubresourceLayers dstSubresource;
    VkOffset3D dstOffset;
    VkExtent3D extent;
} VkImageResolve;
• srcSubresource and dstSubresource are VkImageSubresourceLayers structures specifying the image subresources of the images used for the source and destination image data, respectively. Resolve of depth/stencil images is not supported.

• srcOffset and dstOffset select the initial x, y, and z offsets in texels of the sub-regions of the source and destination image data.

• extent is the size in texels of the source image to resolve in width, height and depth.

Valid Usage

• The aspectMask member of srcSubresource and dstSubresource must only contain VK_IMAGE_ASPECT_COLOR_BIT

• The layerCount member of srcSubresource and dstSubresource must match

• If either of the calling command’s srcImage or dstImage parameters are of VkImageType VK_IMAGE_TYPE_3D, the baseArrayLayer and layerCount members of both srcSubresource and dstSubresource must be 0 and 1, respectively

• srcOffset.x and (extent.width + srcOffset.x) must both be greater than or equal to 0 and less than or equal to the source image subresource width

• srcOffset.y and (extent.height + srcOffset.y) must both be greater than or equal to 0 and less than or equal to the source image subresource height

• If the calling command’s srcImage is of type VK_IMAGE_TYPE_1D, then srcOffset.y must be 0 and extent.height must be 1

• srcOffset.z and (extent.depth + srcOffset.z) must both be greater than or equal to 0 and less than or equal to the source image subresource depth

• If the calling command’s srcImage is of type VK_IMAGE_TYPE_1D or VK_IMAGE_TYPE_2D, then srcOffset.z must be 0 and extent.depth must be 1

• dstOffset.x and (extent.width + dstOffset.x) must both be greater than or equal to 0 and less than or equal to the destination image subresource width

• dstOffset.y and (extent.height + dstOffset.y) must both be greater than or equal to 0 and less than or equal to the destination image subresource height

• If the calling command’s dstImage is of type VK_IMAGE_TYPE_1D, then dstOffset.y must be 0 and extent.height must be 1

• dstOffset.z and (extent.depth + dstOffset.z) must both be greater than or equal to 0 and less than or equal to the destination image subresource depth

• If the calling command’s dstImage is of type VK_IMAGE_TYPE_1D or VK_IMAGE_TYPE_2D, then dstOffset.z must be 0 and extent.depth must be 1

Valid Usage (Implicit)

• srcSubresource must be a valid VkImageSubresourceLayers structure

• dstSubresource must be a valid VkImageSubresourceLayers structure
19.7. Buffer Markers

To write a 32-bit marker value into a buffer as a pipelined operation, call:

```c
void vkCmdWriteBufferMarkerAMD(
    VkCommandBuffer                             commandBuffer,
    VkPipelineStageFlagBits                     pipelineStage,
    VkBuffer                                    dstBuffer,
    VkDeviceSize                                dstOffset,
    uint32_t                                    marker);
```

- `commandBuffer` is the command buffer into which the command will be recorded.
- `pipelineStage` is one of the `VkPipelineStageFlagBits` values, specifying the pipeline stage whose completion triggers the marker write.
- `dstBuffer` is the buffer where the marker will be written to.
- `dstOffset` is the byte offset into the buffer where the marker will be written to.
- `marker` is the 32-bit value of the marker.

The command will write the 32-bit marker value into the buffer only after all preceding commands have finished executing up to at least the specified pipeline stage. This includes the completion of other preceding `vkCmdWriteBufferMarkerAMD` commands so long as their specified pipeline stages occur either at the same time or earlier than this command's specified `pipelineStage`.

While consecutive buffer marker writes with the same `pipelineStage` parameter are implicitly complete in submission order, memory and execution dependencies between buffer marker writes and other operations must still be explicitly ordered using synchronization commands. The access scope for buffer marker writes falls under the `VK_ACCESS_TRANSFER_WRITE_BIT`, and the pipeline stages for identifying the synchronization scope must include both `pipelineStage` and `VK_PIPELINE_STAGE_TRANSFER_BIT`.

**Note**
Similar to `vkCmdWriteTimestamp`, if an implementation is unable to write a marker at any specific pipeline stage, it may instead do so at any logically later stage.

**Note**
Implementations may only support a limited number of pipelined marker write operations in flight at a given time, thus excessive number of marker write operations may degrade command execution performance.
Valid Usage

- `dstOffset` must be less than or equal to the size of `dstBuffer` minus 4
- `dstBuffer` must have been created with `VK_BUFFER_USAGE_TRANSFER_DST_BIT` usage flag
- If `dstBuffer` is non-sparse then it must be bound completely and contiguously to a single `VkDeviceMemory` object
- `dstOffset` must be a multiple of 4

Valid Usage (Implicit)

- `commandBuffer` must be a valid `VkCommandBuffer` handle
- `pipelineStage` must be a valid `VkPipelineStageFlagBits` value
- `dstBuffer` must be a valid `VkBuffer` handle
- `commandBuffer` must be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from must support transfer, graphics, or compute operations
- Both of `commandBuffer`, and `dstBuffer` must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

- Host access to `commandBuffer` must be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Chapter 20. Drawing Commands

_Drawing commands_ (commands with **Draw** in the name) provoke work in a graphics pipeline. Drawing commands are recorded into a command buffer and when executed by a queue, will produce work which executes according to the bound graphics pipeline. A graphics pipeline must be bound to a command buffer before any drawing commands are recorded in that command buffer.

Drawing can be achieved in two modes:

- **Programmable Mesh Shading**, the mesh shader assembles primitives, or
- **Programmable Primitive Shading**, the input primitives are assembled

as follows.

Each draw is made up of zero or more vertices and zero or more instances, which are processed by the device and result in the assembly of primitives. Primitives are assembled according to the `pInputAssemblyState` member of the `VkGraphicsPipelineCreateInfo` structure, which is of type `VkPipelineInputAssemblyStateCreateInfo`:

```c
typedef struct VkPipelineInputAssemblyStateCreateInfo {
    VkStructureType sType;
    const void* pNext;
    VkPipelineInputAssemblyStateCreateFlags flags;
    VkPrimitiveTopology topology;
    VkBool32 primitiveRestartEnable;
} VkPipelineInputAssemblyStateCreateInfo;
```

- **sType** is the type of this structure.
- **pNext** is **NULL** or a pointer to an extension-specific structure.
- **flags** is reserved for future use.
- **topology** is a `VkPrimitiveTopology` defining the primitive topology, as described below.
- **primitiveRestartEnable** controls whether a special vertex index value is treated as restarting the assembly of primitives. This enable only applies to indexed draws (**vkCmdDrawIndexed** and **vkCmdDrawIndexedIndirect**), and the special index value is either 0xFFFFFFFF when the `indexType` parameter of `vkCmdBindIndexBuffer` is equal to `VK_INDEX_TYPE_UINT32`, 0xFF when `indexType` is equal to `VK_INDEX_TYPE_UINT8_EXT`, or 0xFFFF when `indexType` is equal to `VK_INDEX_TYPE_UINT16`. Primitive restart is not allowed for “list” topologies.

Restarting the assembly of primitives discards the most recent index values if those elements formed an incomplete primitive, and restarts the primitive assembly using the subsequent indices, but only assembling the immediately following element through the end of the originally specified elements. The primitive restart index value comparison is performed before adding the `vertexOffset` value to the index value.
20.1. Primitive Topologies

Primitive topology determines how consecutive vertices are organized into primitives, and determines the type of primitive that is used at the beginning of the graphics pipeline. The effective topology for later stages of the pipeline is altered by tessellation or geometry shading (if either is in use) and depends on the execution modes of those shaders. In the case of mesh shading the only effective topology is defined by the execution mode of the mesh shader.

The primitive topologies defined by VkPrimitiveTopology are:
typedef enum VkPrimitiveTopology {
    VK_PRIMITIVE_TOPOLOGY_POINT_LIST = 0,
    VK_PRIMITIVE_TOPOLOGY_LINE_LIST = 1,
    VK_PRIMITIVE_TOPOLOGY_LINE_STRIP = 2,
    VK_PRIMITIVE_TOPOLOGY_TRIANGLE_LIST = 3,
    VK_PRIMITIVE_TOPOLOGY_TRIANGLE_STRIP = 4,
    VK_PRIMITIVE_TOPOLOGY_TRIANGLE_FAN = 5,
    VK_PRIMITIVE_TOPOLOGY_LINE_LIST_WITH_ADJACENCY = 6,
    VK_PRIMITIVE_TOPOLOGY_LINE_STRIP_WITH_ADJACENCY = 7,
    VK_PRIMITIVE_TOPOLOGY_TRIANGLE_LIST_WITH_ADJACENCY = 8,
    VK_PRIMITIVE_TOPOLOGY_TRIANGLE_STRIP_WITH_ADJACENCY = 9,
    VK_PRIMITIVE_TOPOLOGY_PATCH_LIST = 10,
} VkPrimitiveTopology;

• VK_PRIMITIVE_TOPOLOGY_POINT_LIST specifies a series of separate point primitives.
• VK_PRIMITIVE_TOPOLOGY_LINE_LIST specifies a series of separate line primitives.
• VK_PRIMITIVE_TOPOLOGY_LINE_STRIP specifies a series of connected line primitives with consecutive lines sharing a vertex.
• VK_PRIMITIVE_TOPOLOGY_TRIANGLE_LIST specifies a series of separate triangle primitives.
• VK_PRIMITIVE_TOPOLOGY_TRIANGLE_STRIP specifies a series of connected triangle primitives with consecutive triangles sharing an edge.
• VK_PRIMITIVE_TOPOLOGY_TRIANGLE_FAN specifies a series of connected triangle primitives with all triangles sharing a common vertex.
• VK_PRIMITIVE_TOPOLOGY_LINE_LIST_WITH_ADJACENCY specifies a series of separate line primitives with adjacency.
• VK_PRIMITIVE_TOPOLOGY_LINE_STRIP_WITH_ADJACENCY specifies a series of connected line primitives with adjacency, with consecutive primitives sharing three vertices.
• VK_PRIMITIVE_TOPOLOGY_TRIANGLE_LIST_WITH_ADJACENCY specifies a series of separate triangle primitives with adjacency.
• VK_PRIMITIVE_TOPOLOGY_TRIANGLE_STRIP_WITH_ADJACENCY specifies connected triangle primitives with adjacency, with consecutive triangles sharing an edge.
• VK_PRIMITIVE_TOPOLOGY_PATCH_LIST specifies separate patch primitives.

Each primitive topology, and its construction from a list of vertices, is described in detail below with a supporting diagram, according to the following key:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>•</td>
<td>Vertex</td>
</tr>
<tr>
<td>5</td>
<td>Vertex Number</td>
</tr>
<tr>
<td>←</td>
<td>Provoking Vertex</td>
</tr>
</tbody>
</table>

- **Vertex**: A point in 3-dimensional space. Positions chosen within the diagrams are arbitrary and for illustration only.
- **Vertex Number**: Sequence position of a vertex within the provided vertex data.
- **Provoking Vertex**: Provoking vertex within the main primitive. The arrow points along an edge of the relevant primitive, following winding order. Used in flat shading.
### Primitive Edge

An edge connecting the points of a main primitive.

### Adjacency Edge

Points connected by these lines do not contribute to a main primitive, and are only accessible in a geometry shader.

### Winding Order

The relative order in which vertices are defined within a primitive, used in the facing determination. This ordering has no specific start or end point.

The diagrams are supported with mathematical definitions where the vertices (v) and primitives (p) are numbered starting from 0; \( v_0 \) is the first vertex in the provided data and \( p_0 \) is the first primitive in the set of primitives defined by the vertices and topology.

#### 20.1.1. Point Lists

When the topology is `VK_PRIMITIVE_TOPOLOGY_POINT_LIST`, each consecutive vertex defines a single point primitive, according to the equation:

\[
p_i = \{v_i\}
\]

As there is only one vertex, that vertex is the provoking vertex. The number of primitives generated is equal to `vertexCount`.

#### 20.1.2. Line Lists

When the topology is `VK_PRIMITIVE_TOPOLOGY_LINE_LIST`, each consecutive pair of vertices defines a single line primitive, according to the equation:

\[
p_i = \{v_{2i}, v_{2i+1}\}
\]

The provoking vertex for \( p_i \) is \( v_{2i} \). The number of primitives generated is equal to \( \lfloor \text{vertexCount}/2 \rfloor \).
20.1.3. Line Strips

When the topology is VK_PRIMITIVE_TOPOLOGY_LINE_STRIP, one line primitive is defined by each vertex and the following vertex, according to the equation:

\[ p_i = \{v_i, v_{i+1}\} \]

The provoking vertex for \( p_i \) is \( v_i \). The number of primitives generated is equal to \( \max(0, \text{vertexCount} - 1) \).

![Line Strips Diagram]

20.1.4. Triangle Lists

When the topology is VK_PRIMITIVE_TOPOLOGY_TRIANGLE_LIST, each consecutive set of three vertices defines a single triangle primitive, according to the equation:

\[ p_i = \{v_{3i}, v_{3i+1}, v_{3i+2}\} \]

The provoking vertex for \( p_i \) is \( v_{3i} \). The number of primitives generated is equal to \( \lfloor \text{vertexCount}/3 \rfloor \).

![Triangle Lists Diagram]

20.1.5. Triangle Strips

When the topology is VK_PRIMITIVE_TOPOLOGY_TRIANGLE_STRIP, one triangle primitive is defined by each vertex and the two vertices that follow it, according to the equation:

\[ p_i = \{v_i, v_{i+(1+i\%2)}, v_{i+(2-i\%2)}\} \]

The provoking vertex for \( p_i \) is \( v_i \). The number of primitives generated is equal to \( \max(0, \text{vertexCount} - 2) \).

![Triangle Strips Diagram]

**Note**

The ordering of the vertices in each successive triangle is reversed, so that the winding order is consistent throughout the strip.
20.1.6. Triangle Fans

When the topology is VK_PRIMITIVE_TOPOLOGY_TRIANGLE_FAN, triangle primitives are defined around a shared common vertex, according to the equation:

\[ p_i = \{v_{i+1}, v_{i+2}, v_0\} \]

The provoking vertex for \( p_i \) is \( v_{i+1} \). The number of primitives generated is equal to \( \max(0, \text{vertexCount}-2) \).

20.1.7. Line Lists With Adjacency

When the topology is VK_PRIMITIVE_TOPOLOGY_LINE_LIST_WITH_ADJACENCY, each consecutive set of four vertices defines a single line primitive with adjacency, according to the equation:

\[ p_i = \{v_{4i}, v_{4i+1}, v_{4i+2}, v_{4i+3}\} \]

A line primitive is described by the second and third vertices of the total primitive, with the remaining two vertices only accessible in a geometry shader.

The provoking vertex for \( p_i \) is \( v_{4i+1} \). The number of primitives generated is equal to \( \lfloor \text{vertexCount}/4 \rfloor \).

20.1.8. Line Strips With Adjacency

When the topology is VK_PRIMITIVE_TOPOLOGY_LINE_STRIP_WITH_ADJACENCY, one line primitive with adjacency is defined by each vertex and the following vertex, according to the equation:

\[ p_i = \{v_i, v_{i+1}, v_{i+2}, v_{i+3}\} \]

A line primitive is described by the second and third vertices of the total primitive, with the remaining two vertices only accessible in a geometry shader.

The provoking vertex for \( p_i \) is \( v_{i+1} \). The number of primitives generated is equal to \( \max(0, \text{vertexCount}-3) \).
20.1.9. Triangle Lists With Adjacency

When the topology is `VK_PRIMITIVE_TOPOLOGY_TRIANGLE_LIST_WITH_ADJACENCY`, each consecutive set of six vertices defines a single triangle primitive with adjacency, according to the equations:

\[ p_i = \{v_{6i}, v_{6i+1}, v_{6i+2}, v_{6i+3}, v_{6i+4}, v_{6i+5}\} \]

A triangle primitive is described by the first, third, and fifth vertices of the total primitive, with the remaining three vertices only accessible in a geometry shader.

The provoking vertex for \( p_i \) is \( v_{6i} \). The number of primitives generated is equal to \( \lfloor \text{vertexCount}/6 \rfloor \).

20.1.10. Triangle Strips With Adjacency

When the topology is `VK_PRIMITIVE_TOPOLOGY_TRIANGLE_STRIP_WITH_ADJACENCY`, one triangle primitive with adjacency is defined by each vertex and the following 5 vertices.

The number of primitives generated, \( n \), is equal to \( \lfloor \max(0, \text{vertexCount} - 4)/2 \rfloor \).

If \( n=1 \), the primitive is defined as:

\[ p = \{v_0, v_1, v_2, v_5, v_4, v_3\} \]

If \( n>1 \), the total primitive consists of different vertices according to where it is in the strip:

\[ p_i = \{v_{2i}, v_{2i+1}, v_{2i+2}, v_{2i+5}, v_{2i+4}, v_{2i+3}\} \text{ when } i=0 \]

\[ p_i = \{v_{2i}, v_{2i+3}, v_{2i+4}, v_{2i+6}, v_{2i+2}, v_{2i+1}\} \text{ when } i>0, i<n-1, \text{ and } i\%2=1 \]

\[ p_i = \{v_{2i}, v_{2i+2}, v_{2i+3}, v_{2i+6}, v_{2i+4}, v_{2i+5}\} \text{ when } i>0, i<n-1, \text{ and } i\%2=0 \]

\[ p_i = \{v_{2i}, v_{2i+3}, v_{2i+4}, v_{2i+5}, v_{2i+2}, v_{2i+1}\} \text{ when } i=n-1 \text{ and } i\%2=1 \]
\[ p_i = \{v_{2i}, v_{2i+2}, v_{2i+5}, v_{2i+4}, v_{2i+3}\} \text{ when } i=n-1 \text{ and } i\%2=0 \]

A triangle primitive is described by the first, third, and fifth vertices of the total primitive in all cases, with the remaining three vertices only accessible in a geometry shader.

**Note**
The ordering of the vertices in each successive triangle is altered so that the winding order is consistent throughout the strip.

The provoking vertex for \( p_i \) is always \( v_{2i} \).

### 20.1.11. Patch Lists

When the topology is `VK_PRIMITIVE_TOPOLOGY_PATCH_LIST`, each consecutive set of \( m \) vertices defines a single patch primitive, according to the equation:

\[ p_i = \{v_{mi}, v_{mi+1}, \ldots, v_{mi+(m-2)}, v_{mi+(m-1)}\} \]

where \( m \) is equal to `VkPipelineTessellationStateCreateInfo::patchControlPoints`.

Patch lists are never passed to vertex post-processing, and as such no provoking vertex is defined for patch primitives. The number of primitives generated is equal to \( \lfloor \text{vertexCount}/m \rfloor \).
The vertices comprising a patch have no implied geometry, and are used as inputs to tessellation shaders and the fixed-function tessellator to generate new point, line, or triangle primitives.

### 20.2. Primitive Order

Primitives generated by drawing commands progress through the stages of the graphics pipeline in **primitive order**. Primitive order is initially determined in the following way:

1. Submission order determines the initial ordering
2. For indirect draw commands, the order in which accessed instances of the `VkDrawIndirectCommand` are stored in buffer, from lower indirect buffer addresses to higher addresses.
3. If a draw command includes multiple instances, the order in which instances are executed, from lower numbered instances to higher.
4. The order in which primitives are specified by a draw command:
   - For non-indexed draws, from vertices with a lower numbered `vertexIndex` to a higher numbered `vertexIndex`.
   - For indexed draws, vertices sourced from a lower index buffer addresses to higher addresses.
   - For draws using mesh shaders, the order is provided by mesh shading.

Within this order implementations further sort primitives:

5. If tessellation shading is active, by an implementation-dependent order of new primitives generated by tessellation.
6. If geometry shading is active, by the order new primitives are generated by geometry shading.
7. If the polygon mode is not `VK_POLYGON_MODE_FILL`, or `VK_POLYGON_MODE_FILL_RECTANGLE_NV`, by an implementation-dependent ordering of the new primitives generated within the original primitive.

Primitive order is later used to define rasterization order, which determines the order in which fragments output results to a framebuffer.

### 20.3. Programmable Primitive Shading

Once primitives are assembled, they proceed to the vertex shading stage of the pipeline. If the draw includes multiple instances, then the set of primitives is sent to the vertex shading stage multiple times, once for each instance.

It is implementation-dependent whether vertex shading occurs on vertices that are discarded as part of incomplete primitives, but if it does occur then it operates as if they were vertices in complete primitives and such invocations can have side effects.

Vertex shading receives two per-vertex inputs from the primitive assembly stage - the `vertexIndex` and the `instanceIndex`. How these values are generated is defined below, with each command.
Drawing commands fall roughly into two categories:

- Non-indexed drawing commands present a sequential `vertexIndex` to the vertex shader. The sequential index is generated automatically by the device (see Fixed-Function Vertex Processing for details on both specifying the vertex attributes indexed by `vertexIndex`, as well as binding vertex buffers containing those attributes to a command buffer). These commands are:
  - `vkCmdDraw`
  - `vkCmdDrawIndirect`
  - `vkCmdDrawIndirectCountKHR`
  - `vkCmdDrawIndirectCountAMD`

- Indexed drawing commands read index values from an index buffer and use this to compute the `vertexIndex` value for the vertex shader. These commands are:
  - `vkCmdDrawIndexed`
  - `vkCmdDrawIndexedIndirect`
  - `vkCmdDrawIndexedIndirectCountKHR`
  - `vkCmdDrawIndexedIndirectCountAMD`

To bind an index buffer to a command buffer, call:

```c
void vkCmdBindIndexBuffer(
    VkCommandBuffer commandBuffer,
    VkBuffer buffer,
    VkDeviceSize offset,
    VkIndexType indexType);
```

- `commandBuffer` is the command buffer into which the command is recorded.
- `buffer` is the buffer being bound.
- `offset` is the starting offset in bytes within `buffer` used in index buffer address calculations.
- `indexType` is a `VkIndexType` value specifying whether indices are treated as 16 bits or 32 bits.

### Valid Usage

- `offset` must be less than the size of `buffer`
- The sum of `offset` and the address of the range of `VkDeviceMemory` object that is backing `buffer` must be a multiple of the type indicated by `indexType`
- `buffer` must have been created with the `VK_BUFFER_USAGE_INDEX_BUFFER_BIT` flag
- If `buffer` is non-sparse then it must be bound completely and contiguously to a single `VkDeviceMemory` object
- `indexType` must not be `VK_INDEX_TYPE_NONE_KHR`
- If `indexType` is `VK_INDEX_TYPE_UINT8_EXT`, the `indexTypeUint8` feature must be enabled
Valid Usage (Implicit)

• **commandBuffer** must be a valid `VkCommandBuffer` handle
• **buffer** must be a valid `VkBuffer` handle
• **indexType** must be a valid `VkIndexType` value
• **commandBuffer** must be in the recording state
• The `VkCommandPool` that `commandBuffer` was allocated from must support graphics operations
• Both of **buffer**, and **commandBuffer** must have been created, allocated, or retrieved from the same `VkDevice`

Host Synchronization

• Host access to **commandBuffer** must be externally synchronized
• Host access to the `VkCommandPool` that `commandBuffer` was allocated from must be externally synchronized

Command Properties

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Both</td>
<td>Graphics</td>
<td></td>
</tr>
<tr>
<td>Secondary</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Possible values of `vkCmdBindIndexBuffer::indexType`, specifying the size of indices, are:

```c
typedef enum VkIndexType {
    VK_INDEX_TYPE_UINT16 = 0,
    VK_INDEX_TYPE_UINT32 = 1,
    VK_INDEX_TYPE_NONE_KHR = 1000165000,
    VK_INDEX_TYPE_UINT8_EXT = 1000265000,
    VK_INDEX_TYPE_NONE_NV = VK_INDEX_TYPE_NONE_KHR,
} VkIndexType;
```

• `VK_INDEX_TYPE_UINT16` specifies that indices are 16-bit unsigned integer values.
• `VK_INDEX_TYPE_UINT32` specifies that indices are 32-bit unsigned integer values.
• `VK_INDEX_TYPE_NONE_KHR` specifies that no indices are provided.
• `VK_INDEX_TYPE_UINT8_EXT` specifies that indices are 8-bit unsigned integer values.

The parameters for each drawing command are specified directly in the command or read from

Chapter 20. Drawing Commands | 943
buffer memory, depending on the command. Drawing commands that source their parameters from buffer memory are known as *indirect* drawing commands.

All drawing commands interact with the Robust Buffer Access feature.

To record a non-indexed draw, call:

```c
void vkCmdDraw(
    VkCommandBuffer commandBuffer,
    uint32_t vertexCount,
    uint32_t instanceCount,
    uint32_t firstVertex,
    uint32_t firstInstance);
```

- `commandBuffer` is the command buffer into which the command is recorded.
- `vertexCount` is the number of vertices to draw.
- `instanceCount` is the number of instances to draw.
- `firstVertex` is the index of the first vertex to draw.
- `firstInstance` is the instance ID of the first instance to draw.

When the command is executed, primitives are assembled using the current primitive topology and `vertexCount` consecutive vertex indices with the first `vertexIndex` value equal to `firstVertex`. The primitives are drawn `instanceCount` times with `instanceIndex` starting with `firstInstance` and increasing sequentially for each instance. The assembled primitives execute the bound graphics pipeline.
Valid Usage

- If a VkImageView is sampled with \( \text{VK}\_\text{FILTER}\_\text{LINEAR} \) as a result of this command, then the image view’s format features must contain \( \text{VK}\_\text{FORMAT}\_\text{FEATURE}\_\text{SAMPLED}\_\text{IMAGE}\_\text{FILTER}\_\text{LINEAR}\_\text{BIT} \).

- If a VkImageView is accessed using atomic operations as a result of this command, then the image view’s format features must contain \( \text{VK}\_\text{FORMAT}\_\text{FEATURE}\_\text{STORAGE}\_\text{IMAGE}\_\text{ATOMIC}\_\text{BIT} \).

- If a VkImageView is sampled with \( \text{VK}\_\text{FILTER}\_\text{CUBIC}\_\text{EXT} \) as a result of this command, then the image view’s format features must contain \( \text{VK}\_\text{FORMAT}\_\text{FEATURE}\_\text{SAMPLED}\_\text{IMAGE}\_\text{FILTER}\_\text{CUBIC}\_\text{BIT}\_\text{EXT} \).

- Any VkImageView being sampled with \( \text{VK}\_\text{FILTER}\_\text{CUBIC}\_\text{EXT} \) as a result of this command must have a VkImageViewType and format that supports cubic filtering, as specified by \( \text{VkFilterCubicImageViewImageFormatPropertiesEXT}::\text{filterCubic} \) returned by \( \text{vkGetPhysicalDeviceImageFormatProperties2} \).

- Any VkImageView being sampled with \( \text{VK}\_\text{FILTER}\_\text{CUBIC}\_\text{EXT} \) with a reduction mode of either \( \text{VK}\_\text{SAMPLER}\_\text{REDUCTION}\_\text{MODE}\_\text{MIN} \) or \( \text{VK}\_\text{SAMPLER}\_\text{REDUCTION}\_\text{MODE}\_\text{MAX} \) as a result of this command must have a VkImageViewType and format that supports cubic filtering together with \text{minmax} filtering, as specified by \( \text{VkFilterCubicImageViewImageFormatPropertiesEXT}::\text{filterCubicMinmax} \) returned by \( \text{vkGetPhysicalDeviceImageFormatProperties2} \).

- Any VkImage created with a VkImageCreateInfo::flags containing \( \text{VK}\_\text{IMAGE}\_\text{CREATE}\_\text{CORNER}\_\text{SAMPLED}\_\text{BIT}\_\text{NV} \) sampled as a result of this command must only be sampled using a VkSamplerAddressMode of \( \text{VK}\_\text{SAMPLER}\_\text{ADDRESS}\_\text{MODE}\_\text{CLAMP}\_\text{TO}\_\text{EDGE} \).

- For each set \( n \) that is statically used by the VkPipeline bound to the pipeline bind point used by this command, a descriptor set must have been bound to \( n \) at the same pipeline bind point, with a VkPipelineLayout that is compatible for set \( n \), with the VkPipelineLayout used to create the current VkPipeline, as described in Pipeline Layout Compatibility.

- For each push constant that is statically used by the VkPipeline bound to the pipeline bind point used by this command, a push constant value must have been set for the same pipeline bind point, with a VkPipelineLayout that is compatible for push constants, with the VkPipelineLayout used to create the current VkPipeline, as described in Pipeline Layout Compatibility.

- Descriptors in each bound descriptor set, specified via vkCmdBindDescriptorSets, must be valid if they are statically used by the VkPipeline bound to the pipeline bind point used by this command.

- A valid pipeline must be bound to the pipeline bind point used by this command.

- If the VkPipeline object bound to the pipeline bind point used by this command requires any dynamic state, that state must have been set for commandBuffer, and done so after any previously bound pipeline with the corresponding state not specified as dynamic.

- There must not have been any calls to dynamic state setting commands for any state not specified as dynamic in the VkPipeline object bound to the pipeline bind point used by this command, since that pipeline was bound.

- If the VkPipeline object bound to the pipeline bind point used by this command accesses a VkSampler object that uses unnormalized coordinates, that sampler must not be used to...
sample from any VkImage with a VkImageView of the type VK_IMAGE_VIEW_TYPE_3D,
VK_IMAGE_VIEW_TYPE_CUBE, VK_IMAGE_VIEW_TYPE_1D_ARRAY, VK_IMAGE_VIEW_TYPE_2D_ARRAY or
VK_IMAGE_VIEW_TYPE_CUBE_ARRAY, in any shader stage

- If the VkPipeline object bound to the pipeline bind point used by this command accesses a
  VkSampler object that uses unnormalized coordinates, that sampler must not be used with
  any of the SPIR-V OpImageSample* or OpImageSparseSample* instructions with ImplicitLod,
  Dref or Proj in their name, in any shader stage

- If the VkPipeline object bound to the pipeline bind point used by this command accesses a
  VkSampler object that uses unnormalized coordinates, that sampler must not be used with
  any of the SPIR-V OpImageSample* or OpImageSparseSample* instructions that includes a LOD
  bias or any offset values, in any shader stage

- If the robust buffer access feature is not enabled, and if the VkPipeline object bound to the
  pipeline bind point used by this command accesses a uniform buffer, it must not access
  values outside of the range of the buffer as specified in the descriptor set bound to the
  same pipeline bind point

- If the robust buffer access feature is not enabled, and if the VkPipeline object bound to the
  pipeline bind point used by this command accesses a storage buffer, it must not access
  values outside of the range of the buffer as specified in the descriptor set bound to the
  same pipeline bind point

- The current render pass must be compatible with the renderPass member of the
  VkGraphicsPipelineCreateInfo structure specified when creating the VkPipeline bound to
  VK_PIPELINE_BIND_POINT_GRAPHICS

- The subpass index of the current render pass must be equal to the subpass member of the
  VkGraphicsPipelineCreateInfo structure specified when creating the VkPipeline bound to
  VK_PIPELINE_BIND_POINT_GRAPHICS

- Every input attachment used by the current subpass must be bound to the pipeline via a
descriptor set

- Image subresources used as attachments in the current render pass must not be accessed
  in any way other than as an attachment by this command

- If the draw is recorded in a render pass instance with multiview enabled, the maximum
  instance index must be less than or equal to VkPhysicalDeviceMultiviewProperties::maxMultiviewInstanceIndex

- If the bound graphics pipeline was created with
  VkPipelineSampleLocationsStateCreateInfoEXT::sampleLocationsEnable set to VK_TRUE and
  the current subpass has a depth/stencil attachment, then that attachment must have been
  created with the VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT bit set

- All vertex input bindings accessed via vertex input variables declared in the vertex
  shader entry point's interface must have either valid or VK_NULL_HANDLE buffers bound

- If the nullDescriptor feature is not enabled, all vertex input bindings accessed via vertex
  input variables declared in the vertex shader entry point's interface must not be
  VK_NULL_HANDLE

- For a given vertex buffer binding, any attribute data fetched must be entirely contained
within the corresponding vertex buffer binding, as described in Vertex Input Description

Valid Usage (Implicit)

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `commandBuffer` **must** be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics operations
- This command **must** only be called inside of a render pass instance

Host Synchronization

- Host access to `commandBuffer` **must** be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized

To record an indexed draw, call:

```c
void vkCmdDrawIndexed(
    VkCommandBuffer                             commandBuffer,  
    uint32_t                                    indexCount,       
    uint32_t                                    instanceCount,    
    uint32_t                                    firstIndex,       
    int32_t                                     vertexOffset,     
    uint32_t                                    firstInstance);   
```

- `commandBuffer` is the command buffer into which the command is recorded.
- `indexCount` is the number of vertices to draw.
- `instanceCount` is the number of instances to draw.
- `firstIndex` is the base index within the index buffer.
- `vertexOffset` is the value added to the vertex index before indexing into the vertex buffer.
- `firstInstance` is the instance ID of the first instance to draw.
When the command is executed, primitives are assembled using the current primitive topology and
indexCount vertices whose indices are retrieved from the index buffer. The index buffer is treated
as an array of tightly packed unsigned integers of size defined by the vkCmdBindIndexBuffer
::indexType parameter with which the buffer was bound.

The first vertex index is at an offset of firstIndex * indexSize + offset within the bound index
buffer, where offset is the offset specified by vkCmdBindIndexBuffer and indexSize is the byte size of
the type specified by indexType. Subsequent index values are retrieved from consecutive locations
in the index buffer. Indices are first compared to the primitive restart value, then zero extended to
32 bits (if the indexType is VK_INDEX_TYPE_UINT8_EXT or VK_INDEX_TYPE_UINT16) and have vertexOffset
added to them, before being supplied as the vertexIndex value.

The primitives are drawn instanceCount times with instanceIndex starting with firstInstance and
increasing sequentially for each instance. The assembled primitives execute the bound graphics
pipeline.
Valid Usage

- If a VkImageView is sampled with VK_FILTER_LINEAR as a result of this command, then the image view's format features must contain VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_LINEAR_BIT.

- If a VkImageView is accessed using atomic operations as a result of this command, then the image view's format features must contain VK_FORMAT_FEATURE_STORAGE_IMAGE_ATOMIC_BIT.

- If a VkImageView is sampled with VK_FILTER_CUBIC_EXT as a result of this command, then the image view's format features must contain VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_CUBIC_BIT_EXT.

- Any VkImageView being sampled with VK_FILTER_CUBIC_EXT as a result of this command must have a VkImageViewType and format that supports cubic filtering, as specified by VkFilterCubicImageViewImageFormatPropertiesEXT::filterCubic returned by vkGetPhysicalDeviceImageFormatProperties2.

- Any VkImageView being sampled with VK_FILTER_CUBIC_EXT with a reduction mode of either VK_SAMPLER_REDUCTION_MODE_MIN or VK_SAMPLER_REDUCTION_MODE_MAX as a result of this command must have a VkImageViewType and format that supports cubic filtering together with minmax filtering, as specified by VkFilterCubicImageViewImageFormatPropertiesEXT::filterCubicMinmax returned by vkGetPhysicalDeviceImageFormatProperties2.

- Any VkImage created with a VkImageCreateInfo::flags containing VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV sampled as a result of this command must only be sampled using a VkSamplerAddressMode of VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE.

- For each set \( n \) that is statically used by the VkPipeline bound to the pipeline bind point used by this command, a descriptor set must have been bound to \( n \) at the same pipeline bind point, with a VkPipelineLayout that is compatible for set \( n \), with the VkPipelineLayout used to create the current VkPipeline, as described in Pipeline Layout Compatibility.

- For each push constant that is statically used by the VkPipeline bound to the pipeline bind point used by this command, a push constant value must have been set for the same pipeline bind point, with a VkPipelineLayout that is compatible for push constants, with the VkPipelineLayout used to create the current VkPipeline, as described in Pipeline Layout Compatibility.

- Descriptors in each bound descriptor set, specified via vkCmdBindDescriptorSets, must be valid if they are statically used by the VkPipeline bound to the pipeline bind point used by this command.

- A valid pipeline must be bound to the pipeline bind point used by this command.

- If the VkPipeline object bound to the pipeline bind point used by this command requires any dynamic state, that state must have been set for commandBuffer, and done so after any previously bound pipeline with the corresponding state not specified as dynamic.

- There must not have been any calls to dynamic state setting commands for any state not specified as dynamic in the VkPipeline object bound to the pipeline bind point used by this command, since that pipeline was bound.

- If the VkPipeline object bound to the pipeline bind point used by this command accesses a VkSampler object that uses unnormalized coordinates, that sampler must not be used to...
sample from any VkImage with a VkImageView of the type VK_IMAGE_VIEW_TYPE_3D, VK_IMAGE_VIEW_TYPE_CUBE, VK_IMAGE_VIEW_TYPE_1D_ARRAY, VK_IMAGE_VIEW_TYPE_2D_ARRAY or VK_IMAGE_VIEW_TYPE_CUBE_ARRAY, in any shader stage

• If the VkPipeline object bound to the pipeline bind point used by this command accesses a VkSampler object that uses unnormalized coordinates, that sampler must not be used with any of the SPIR-V OpImageSample* or OpImageSparseSample* instructions with ImplicitLod, Dref or Proj in their name, in any shader stage

• If the VkPipeline object bound to the pipeline bind point used by this command accesses a VkSampler object that uses unnormalized coordinates, that sampler must not be used with any of the SPIR-V OpImageSample* or OpImageSparseSample* instructions that includes a LOD bias or any offset values, in any shader stage

• If the robust buffer access feature is not enabled, and if the VkPipeline object bound to the pipeline bind point used by this command accesses a uniform buffer, it must not access values outside of the range of the buffer as specified in the descriptor set bound to the same pipeline bind point

• If the robust buffer access feature is not enabled, and if the VkPipeline object bound to the pipeline bind point used by this command accesses a storage buffer, it must not access values outside of the range of the buffer as specified in the descriptor set bound to the same pipeline bind point

• The current render pass must be compatible with the renderPass member of the VkGraphicsPipelineCreateInfo structure specified when creating the VkPipeline bound to VK_PIPELINE_BIND_POINT_GRAPHICS

• The subpass index of the current render pass must be equal to the subpass member of the VkGraphicsPipelineCreateInfo structure specified when creating the VkPipeline bound to VK_PIPELINE_BIND_POINT_GRAPHICS

• Every input attachment used by the current subpass must be bound to the pipeline via a descriptor set

• Image subresources used as attachments in the current render pass must not be accessed in any way other than as an attachment by this command

• If the draw is recorded in a render pass instance with multiview enabled, the maximum instance index must be less than or equal to VkPhysicalDeviceMultiviewProperties::maxMultiviewInstanceIndex

• If the bound graphics pipeline was created with VkPipelineSampleLocationsStateCreateInfoEXT::sampleLocationsEnable set to VK_TRUE and the current subpass has a depth/stencil attachment, then that attachment must have been created with the VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT bit set

• All vertex input bindings accessed via vertex input variables declared in the vertex shader entry point’s interface must have either valid or VK_NULL_HANDLE buffers bound

• If the nullDescriptor feature is not enabled, all vertex input bindings accessed via vertex input variables declared in the vertex shader entry point’s interface must not be VK_NULL_HANDLE

• For a given vertex buffer binding, any attribute data fetched must be entirely contained
within the corresponding vertex buffer binding, as described in **Vertex Input Description**

- \([(\text{indexSize} \times (\text{firstIndex} + \text{indexCount}) + \text{offset}) \text{ must be less than or equal to the size of the bound index buffer, with indexSize being based on the type specified by indexType, where the index buffer, indexType, and offset are specified via vkCmdBindIndexBuffer}]

**Valid Usage (Implicit)**

- `commandBuffer` **must** be a valid `VkCommandBuffer` handle
- `commandBuffer` **must** be in the recording state
- The `VkCommandPool` that `commandBuffer` was allocated from **must** support graphics operations
- This command **must** only be called inside of a render pass instance

**Host Synchronization**

- Host access to `commandBuffer` **must** be externally synchronized
- Host access to the `VkCommandPool` that `commandBuffer` was allocated from **must** be externally synchronized

**Command Properties**

<table>
<thead>
<tr>
<th>Command Buffer Levels</th>
<th>Render Pass Scope</th>
<th>Supported Queue Types</th>
<th>Pipeline Type</th>

To record a non-indexed indirect draw, call:

```c
void vkCmdDrawIndirect(
    VkCommandBuffer commandBuffer,
    VkBuffer buffer,
    VkDeviceSize offset,
    uint32_t drawCount,
    uint32_t stride);
```

- `commandBuffer` is the command buffer into which the command is recorded.
- `buffer` is the buffer containing draw parameters.
- `offset` is the byte offset into `buffer` where parameters begin.
- `drawCount` is the number of draws to execute, and can be zero.
• **stride** is the byte stride between successive sets of draw parameters.

*vkCmdDrawIndirect* behaves similarly to *vkCmdDraw* except that the parameters are read by the device from a buffer during execution. *drawCount* draws are executed by the command, with parameters taken from *buffer* starting at *offset* and increasing by *stride* bytes for each successive draw. The parameters of each draw are encoded in an array of *VkDrawIndirectCommand* structures. If *drawCount* is less than or equal to one, *stride* is ignored.
Valid Usage

• If a VkImageView is sampled with VK_FILTER_LINEAR as a result of this command, then the image view’s format features must contain VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_LINEAR_BIT

• If a VkImageView is accessed using atomic operations as a result of this command, then the image view’s format features must contain VK_FORMAT_FEATURE_STORAGE_IMAGE_ATOMIC_BIT

• If a VkImageView is sampled with VK_FILTER_CUBIC_EXT as a result of this command, then the image view’s format features must contain VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_CUBIC_BIT_EXT

• If any VkImageView being sampled with VK_FILTER_CUBIC_EXT as a result of this command must have a VkImageViewType and format that supports cubic filtering, as specified by VkFilterCubicImageViewImageFormatPropertiesEXT::filterCubic returned by vkGetPhysicalDeviceImageFormatProperties2

• Any VkImageView being sampled with VK_FILTER_CUBIC_EXT with a reduction mode of either VK_SAMPLER_REDUCTION_MODE_MIN or VK_SAMPLER_REDUCTION_MODE_MAX as a result of this command must have a VkImageViewType and format that supports cubic filtering together with minmax filtering, as specified by VkFilterCubicImageViewImageFormatPropertiesEXT::filterCubicMinmax returned by vkGetPhysicalDeviceImageFormatProperties2

• Any VkImage created with a VkImageCreateInfo::flags containing VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV sampled as a result of this command must only be sampled using a VkSamplerAddressMode of VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE

• For each set n that is statically used by the VkPipeline bound to the pipeline bind point used by this command, a descriptor set must have been bound to n at the same pipeline bind point, with a VkPipelineLayout that is compatible for set n, with the VkPipelineLayout used to create the current VkPipeline, as described in Pipeline Layout Compatibility

• For each push constant that is statically used by the VkPipeline bound to the pipeline bind point used by this command, a push constant value must have been set for the same pipeline bind point, with the VkPipelineLayout that is compatible for push constants, with the VkPipelineLayout used to create the current VkPipeline, as described in Pipeline Layout Compatibility

• Descriptors in each bound descriptor set, specified via vkCmdBindDescriptorSets, must be valid if they are statically used by the VkPipeline bound to the pipeline bind point used by this command

• A valid pipeline must be bound to the pipeline bind point used by this command

• If the VkPipeline object bound to the pipeline bind point used by this command requires any dynamic state, that state must have been set for commandBuffer, and done so after any previously bound pipeline with the corresponding state not specified as dynamic

• There must not have been any calls to dynamic state setting commands for any state not specified as dynamic in the VkPipeline object bound to the pipeline bind point used by this command, since that pipeline was bound

• If the VkPipeline object bound to the pipeline bind point used by this command accesses a VkSampler object that uses unnormalized coordinates, that sampler must not be used to
sample from any VkImage with a VkImageView of the type VK_IMAGE_VIEW_TYPE_3D, VK_IMAGE_VIEW_TYPE_CUBE, VK_IMAGE_VIEW_TYPE_1D_ARRAY, VK_IMAGE_VIEW_TYPE_2D_ARRAY or VK_IMAGE_VIEW_TYPE_CUBE_ARRAY, in any shader stage

- If the VkPipeline object bound to the pipeline bind point used by this command accesses a VkSampler object that uses unnormalized coordinates, that sampler must not be used with any of the SPIR-V OpImageSample* or OpImageSparseSample* instructions with ImplicitLod, Dref or Proj in their name, in any shader stage
- If the VkPipeline object bound to the pipeline bind point used by this command accesses a VkSampler object that uses unnormalized coordinates, that sampler must not be used with any of the SPIR-V OpImageSample* or OpImageSparseSample* instructions that includes a LOD bias or any offset values, in any shader stage
- If the robust buffer access feature is not enabled, and if the VkPipeline object bound to the pipeline bind point used by this command accesses a uniform buffer, it must not access values outside of the range of the buffer as specified in the descriptor set bound to the same pipeline bind point
- If the robust buffer access feature is not enabled, and if the VkPipeline object bound to the pipeline bind point used by this command accesses a storage buffer, it must not access values outside of the range of the buffer as specified in the descriptor set bound to the same pipeline bind point
- The current render pass must be compatible with the renderPass member of the VkGraphicsPipelineCreateInfo structure specified when creating the VkPipeline bound to VK_PIPELINE_BIND_POINT_GRAPHICS
- The subpass index of the current render pass must be equal to the subpass member of the VkGraphicsPipelineCreateInfo structure specified when creating the VkPipeline bound to VK_PIPELINE_BIND_POINT_GRAPHICS
- Every input attachment used by the current subpass must be bound to the pipeline via a descriptor set
- Image subresources used as attachments in the current render pass must not be accessed in any way other than as an attachment by this command
- If the draw is recorded in a render pass instance with multiview enabled, the maximum instance index must be less than or equal to VkPhysicalDeviceMultiviewProperties::maxMultiviewInstanceIndex
- If the bound graphics pipeline was created with VkPipelineSampleLocationsStateCreateInfoEXT::sampleLocationsEnable set to VK_TRUE and the current subpass has a depth/stencil attachment, then that attachment must have been created with the VK_IMAGE_CREATE_SAMPLE_LOCATIONS_COMPATIBLE_DEPTH_BIT_EXT bit set
- All vertex input bindings accessed via vertex input variables declared in the vertex shader entry point's interface must have either valid or VK_NULL_HANDLE buffers bound
- If the nullDescriptor feature is not enabled, all vertex input bindings accessed via vertex input variables declared in the vertex shader entry point's interface must not be VK_NULL_HANDLE
- For a given vertex buffer binding, any attribute data fetched must be entirely contained
within the corresponding vertex buffer binding, as described in Vertex Input Description

- If buffer is non-sparse then it **must** be bound completely and contiguously to a single VkDeviceMemory object
- buffer **must** have been created with the VK_BUFFER_USAGE_INDIRECT_BUFFER_BIT bit set
- offset **must** be a multiple of 4
- If the multi-draw indirect feature is not enabled, drawCount **must** be 0 or 1
- drawCount **must** be less than or equal to VkPhysicalDeviceLimits::maxDrawIndirectCount
- If the drawIndirectFirstInstance feature is not enabled, all the firstInstance members of the VkDrawIndirectCommand structures accessed by this command **must** be 0
- If drawCount is greater than 1, stride **must** be a multiple of 4 and **must** be greater than or equal to sizeof(VkDrawIndirectCommand)
- If drawCount is equal to 1, (offset + sizeof(VkDrawIndirectCommand)) **must** be less than or equal to the size of buffer
- If drawCount is greater than 1, (stride × (drawCount - 1) + offset + sizeof(VkDrawIndirectCommand)) **must** be less than or equal to the size of buffer

**Valid Usage (Implicit)**

- commandBuffer **must** be a valid VkCommandBuffer handle
- buffer **must** be a valid VkBuffer handle
- commandBuffer **must** be in the recording state
- The VkCommandPool that commandBuffer was allocated from **must** support graphics operations
- This command **must** only be called inside of a render pass instance
- Both of buffer, and commandBuffer **must** have been created, allocated, or retrieved from the same VkDevice

**Host Synchronization**

- Host access to commandBuffer **must** be externally synchronized
- Host access to the VkCommandPool that commandBuffer was allocated from **must** be externally synchronized
The `VkDrawIndirectCommand` structure is defined as:

```c
typedef struct VkDrawIndirectCommand {
    uint32_t    vertexCount;
    uint32_t    instanceCount;
    uint32_t    firstVertex;
    uint32_t    firstInstance;
} VkDrawIndirectCommand;
```

- `vertexCount` is the number of vertices to draw.
- `instanceCount` is the number of instances to draw.
- `firstVertex` is the index of the first vertex to draw.
- `firstInstance` is the instance ID of the first instance to draw.

The members of `VkDrawIndirectCommand` have the same meaning as the similarly named parameters of `vkCmdDraw`.

### Valid Usage

- For a given vertex buffer binding, any attribute data fetched must be entirely contained within the corresponding vertex buffer binding, as described in Vertex Input Description.
- If the `drawIndirectFirstInstance` feature is not enabled, `firstInstance` must be 0.

To record a non-indexed draw call with a draw call count sourced from a buffer, call:

```c
void vkCmdDrawIndirectCountKHR(
    VkCommandBuffer                             commandBuffer,
    VkBuffer                                    buffer,
    VkDeviceSize                                offset,
    VkBuffer                                    countBuffer,
    VkDeviceSize                                countBufferOffset,
    uint32_t                                    maxDrawCount,
    uint32_t                                    stride);
```

or the equivalent command
```c
void vkCmdDrawIndirectCountAMD(
    VkCommandBuffer                             commandBuffer,
    VkBuffer                                    buffer,
    VkDeviceSize                                offset,
    VkBuffer                                    countBuffer,
    VkDeviceSize                                countBufferOffset,
    uint32_t                                    maxDrawCount,
    uint32_t                                    stride);
```

- `commandBuffer` is the command buffer into which the command is recorded.
- `buffer` is the buffer containing draw parameters.
- `offset` is the byte offset into `buffer` where parameters begin.
- `countBuffer` is the buffer containing the draw count.
- `countBufferOffset` is the byte offset into `countBuffer` where the draw count begins.
- `maxDrawCount` specifies the maximum number of draws that will be executed. The actual number of executed draw calls is the minimum of the count specified in `countBuffer` and `maxDrawCount`.
- `stride` is the byte stride between successive sets of draw parameters.

`vkCmdDrawIndirectCount` behaves similarly to `vkCmdDrawIndirect` except that the draw count is read by the device from a buffer during execution. The command will read an unsigned 32-bit integer from `countBuffer` located at `countBufferOffset` and use this as the draw count.
Valid Usage

- If a VkImageView is sampled with VK_FILTER_LINEAR as a result of this command, then the image view's format features must contain VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_LINEAR_BIT.

- If a VkImageView is accessed using atomic operations as a result of this command, then the image view's format features must contain VK_FORMAT_FEATURE_STORAGE_IMAGE_ATOMIC_BIT.

- If a VkImageView is sampled with VK_FILTER_CUBIC_EXT as a result of this command, then the image view's format features must contain VK_FORMAT_FEATURE_SAMPLED_IMAGE_FILTER_CUBIC_BIT_EXT.

- Any VkImageView being sampled with VK_FILTER_CUBIC_EXT as a result of this command must have a VkImageViewType and format that supports cubic filtering, as specified by VkFilterCubicImageViewImageFormatPropertiesEXT::filterCubic returned by vkGetPhysicalDeviceImageFormatProperties2.

- Any VkImageView being sampled with VK_FILTER_CUBIC_EXT with a reduction mode of either VK_SAMPLER_REDUCTION_MODE_MIN or VK_SAMPLER_REDUCTION_MODE_MAX as a result of this command must have a VkImageViewType and format that supports cubic filtering together with minmax filtering, as specified by VkFilterCubicImageViewImageFormatPropertiesEXT::filterCubicMinmax returned by vkGetPhysicalDeviceImageFormatProperties2.

- Any VkImage created with a VkImageCreateInfo::flags containing VK_IMAGE_CREATE_CORNER_SAMPLED_BIT_NV sampled as a result of this command must only be sampled using a VkSamplerAddressMode of VK_SAMPLER_ADDRESS_MODE_CLAMP_TO_EDGE.

- For each set $n$ that is statically used by the VkPipeline bound to the pipeline bind point used by this command, a descriptor set must have been bound to $n$ at the same pipeline bind point, with a VkPipelineLayout that is compatible for set $n$, with the VkPipelineLayout used to create the current VkPipeline, as described in Pipeline Layout Compatibility.
